and where desired or necessary converting the resultant compound of formula I, or another salt thereof, to a pharmaceutically acceptable salt thereof, or vice versa.

In process (a) the reaction of compounds of formulae II and III may be carried out by stirring the reactants in an inert solvent at a temperature between room temperature and the boiling point of the solvent, or without solvent at a temperature between room temperature and  $200^\circ\text{C}$ . for a period of 1 to 72 hours, or until reaction is complete. We have found that it is frequently desirable to use the carbonyl compound III in protected form as an acetal or ketal; we find the ethylene ketal to be particularly suitable for ketones. Eth-

ylene ketals may be formed readily by condensing a ketone with ethylene glycol under conditions well known in the art.

In process (b) the alkylation reaction may be performed by processes well known in the art. For example, the amine can be reacted with an alkyl halide, especially the bromide or iodide.

In process (c) the reduction may be carried out catalytically by stirring the reactant in an inert solvent under an atmosphere of hydrogen in the presence of a metal catalyst, or for example by the action of a metal or metal halide (e.g. iron, tin or tin(II) chloride) in an acid, e.g. hydrochloric acid.

In process (d) the reaction of the acid and amine may be carried out in an inert solvent in the presence of a condensing agent, for example  $\text{N,N}'$ -carbonyldiimidazole or dicyclohexylcarbodiimide, or the acid may be first activated by conversion to e.g. and acyl chloride before reaction with the amine.

In processes (e) and (f) the reaction may be performed by combining the reactants in an inert solvent at ambient temperature in the presence of a base e.g. pyridine or triethylamine. Although a number of leaving groups  $\text{L}$  might be suitable we prefer that  $\text{L}$  represent a halogen, especially chlorine or bromine.

In process (g) the esterification reaction may be performed under conditions well known to a person skilled in the art. For example, the acid, which may be optionally activated (e.g. as the acyl chloride), may be reacted with an appropriate alcohol under conditions of acid or basic catalysis.

In process (h), protecting groups for amines and hydroxyl groups include, alky, aralkyl, acyl, alkoxyacyl, alkylsulphonyl, arylsulphonyl and triallylsilyl. When the group is alkyl, acyl, or alkoxyacyl this group may be removed by hydrolysis. Aralkyl groups may be removed by hydrogenolysis. Alkylsulphonyl or arylsulphonyl groups may be removed by reduction with, for example, zinc and acetic acid or sodium and ammonia. Trialkylsilyl groups may be removed by reaction with tetra-*n*-butylammonium fluoride. Other protecting groups and further details of processes for their removal may be found by reference to the standard text "Protecting Groups in Organic Synthesis", 2nd. Edition (1991) by Greene and Wuts.

In process (i), suitable leaving groups  $\text{L}''$  include chlorine, alkoxy, alkylthio and trifluoromethanesulphonyloxy. The reaction may be carried out with ammonia in a solvent, or with a metal amide salt.

In processes (j) and (k), any suitable means of reduction may be used, such as catalytic hydrogenation or reaction with a hydride reagent.

Salts of compounds of formula I may be formed by reacting the free base or a salt thereof, with one or more equivalents of the appropriate acid. The reaction may be carried out in a solvent or medium in which the salt is insoluble e.g. diethyl ether or in a solvent in which the salt is soluble e.g. dioxane, ethanol, tetrahydrofuran or water, or a mixture of solvents which may be removed in vacuo or by freeze drying. The reaction may be a metathetical process or it may be carried out on an ion exchange resin.

Compounds of formula II may be prepared by reduction of compounds of formula VI:

wherein  $R^1$ ,  $R^2$  and  $R^{19}$  are as defined above.

This reaction process may be performed by treating the compound with Raney nickel and hydrogen gas in a polar solvent e.g. ethanol at elevated temperature and pressure, typically  $65^\circ\text{C}$ . and 3 atmospheres pressure. Alternative reaction procedures which are considered suitable include treatment of the compound of formula VI under a hydrogen atmosphere with palladium on charcoal or rhodium on alumina.

Compounds of formula VI may be prepared by reaction of a compound of formula VII:

wherein  $R^1$ ,  $R^2$  and  $R^{19}$  are as defined above,

with hydroxylamine hydrochloride.

In this reaction the two reactants may be heated in the presence of a base, such as sodium methoxide in a solvent e.g. methanol.

Alternative preparation methods for compounds of formula II include, reaction of a compound of formula VII with ammonium chloride in the presence of a trialkylaluminium reagent, or reaction of a compound formula VII with a primary alcohol e.g. ethanol in the presence of acid and subsequent treatment with ammonium chloride.

Compounds of formula II in which  $R^{19}$  is 5-hydroxy may be prepared by reduction of a benzisoxazole derivative of formula VIII:

in which R represents  $-\text{NO}_2$ , to give the compound in which  $R^2$  represents hydrogen, or  $-\text{NHR}^2$  and  $R^1$  and  $R^2$  are as previously defined.

In this reaction the reduction may be carried out by stirring the compound of formula VIII with Raney nickel under hydrogen in a polar solvent e.g. ethanol at elevated temperatures and pressures typically  $65^\circ\text{C}$ . and 3 atmospheres pressure.

Compounds of formula VIII may be prepared by reaction of a compound of formula

The compounds of formula I, and pharmaceutically acceptable salts thereof, are useful because they possess pharmacological activity in animals. In particular, the compounds are active as inhibitors of the inducible isoform of the enzyme nitric oxide synthase and as such are expected to be useful as anti-inflammatory agents.

The activity of compounds according to the invention was tested in the following screen:

The activity of compounds of formula I, or a pharmaceutically acceptable salt thereof, may be screened for nitric oxide synthase inhibiting activity by a procedure based on that of Förstermarm et al. (1992), *Eur. J. Pharm.* 225, 161-165. Nitric oxide synthase converts [<sup>3</sup>H]-L-arginine to [<sup>3</sup>H]-L-citrulline which can be separated by cation exchange chromatography and quantified by liquid scintillation counting.

Enzyme is prepared, after induction, from the cultured murine macrophage cell line J774A-1 (obtained from the laboratories of the Imperial Cancer Research Fund). J774A-1 cells are cultured in Dulbeccos Modified Eagles Medium (DMEM) supplemented with 10% foetal bovine serum, 4 mM L-glutamine and antibiotics (100 units/ml penicillin G, 100 µg/ml streptomycin & 0.25 µg/ml amphotericin B). Cells are routinely grown in 225 cm<sup>3</sup> flasks

containing 35 ml medium kept at 37° C. and in a humidified atmosphere containing 5% CO<sub>2</sub>.

Nitric oxide synthase is produced by J774A-1 cells in response to interferon-γ (IFN<sub>γ</sub>) and lipopolysaccharide (LPS). The medium from confluent culture flasks is removed and is replaced with 25 ml (per flask) of fresh medium containing 1 µg/ml LPS and 10 units/ml IFN<sub>γ</sub>. After a period of 17-20 hours in culture, harvesting of cells is accomplished by scraping the cell sheet from the flask surface into the culture medium. Cells are collected by centrifugation (1000 g for 10 minutes) and lysate prepared by adding to the cell pellet a solution containing 50 mM Tris-HCl (pH 7.5 at 20° C.), 10% (v/v) glycerol, 0.1% (v/v) Triton-X-100, 0.1 mM dithiothreitol and a cocktail of protease inhibitors comprising leupeptin (2 µg/ml), soya bean trypsin inhibitor (10 µg/ml), aprotinin (5 µg/ml) and phenylmethylsulphonyl fluoride (50 µg/ml).

For the assay, 25 µl substrate cocktail (50 mM Tris-HCl (pH 7.5 at 20° C.), 400 µM NADPH, 20 µM flavin adenine dinucleotide, 20 µM flavin mononucleotide, 4 µM tetrahydrobiopterin, 12 µM L-arginine and 0.025 mCi L-[<sup>3</sup>H] arginine) is added to wells of a 96 well filter plate (0.45 µm pore size) containing 25 µl of a solution of test compound in 50 mM Tris-HCl. The reaction is started by adding 50 µl of cell lysate (prepared as above) and after incubation for 1 hour at room temperature is terminated by addition of 50 µl of an aqueous solution of 3 mM nitroarginine and 21 mM EDTA.

Labelled L-citrulline is separated from labelled L-arginine using Dowex AG-50W. 150 µl of a 25% aqueous slurry of Dowex 50W (Na<sup>+</sup> form) is added to the assay after which the whole is filtered into 96 well plates. 75 µl of filtrate is sampled and added to wells of 96 well plates containing solid scintillant. After allowing the samples to dry the L-citrulline is quantified by scintillation counting.

In a typical experiment basal activity is 300 dpm per 75 µl sample which is increased to 1900 dpm in the reagent controls. Compound activity is expressed as IC<sub>50</sub> (the concentration of drug substance which gives 50% enzyme inhibition in the assay) and aminoguanidine, which gives an IC<sub>50</sub> (50% inhibitory concentration) of 10 µM, is tested as a standard to verify the procedure. Compounds are tested at a range of concentrations and from the inhibitions obtained IC<sub>50</sub> values are calculated. Compounds that inhibit the enzyme by at least 25% at 100 µM are classed as being active and are subjected to at least one retest.

In the above screen, the compounds were tested and most gave IC<sub>50</sub> values of less than 25 µM indicating that they are expected to show useful therapeutic activity.

Compounds also show activity against the human form of induced nitric oxide synthase as can be demonstrated in the following assay.

Enzyme is prepared, after induction, from the cultured human colon adenocarcinoma cell line DLD1 (obtained from the European Collection of Animal Cell Culture—cell line number 90102540). DLD1 cells are cultured in RPMI 1640 medium supplemented with 10% foetal bovine serum, 4 mM L-glutamine and antibiotics (100 units/ml penicillin G, 100 µg/ml streptomycin and 0.25 µg/ml amphotericin B). Cells are routinely grown in 225 cm<sup>3</sup> flasks containing 35 ml kept at 37° C. and in a humidified atmosphere containing 5% CO<sub>2</sub>.

Nitric oxide synthase is produced by cells in response to interferon-γ (IFN-γ) and inter-leukin-1β (IL-1β). The medium from confluent flasks is removed and replaced with 25 ml (per flask) of fresh medium containing 250 units/ml IL-1β and 1000 units/ml IFN-γ. After a period of 17-20 hours in culture, harvesting of cells is accomplished by

scraping the cell monolayer from the flask surface into the culture medium. Cells are collected by centrifugation (1000 g for 10 minutes) and lysate prepared by adding to the cell pellet a solution containing 50 mM Tris-HCl (pH 7.5 at 20° C.), 10% (v/v) glycerol, 0.1% (v/v) Triton-X100, 0.1 mM 5 dithiothreitol and a cocktail of protease inhibitors including leupeptin (2 µg/ml), soya bean trypsin inhibitor (10 µg/ml), aprotonin (5 µg/ml) and phenylmethylsulphonyl fluoride (50 µg/ml).

For the assay, 25 µl of substrate cocktail (50 mM Tris-HCl 10 (pH 7.5), 400 µM NADPH, 20 µM flavin adenine dinucleotide, 20 µM flavin mononucleotide and 4 µM tetrahydrobiopterin) is added to the wells of a 96-well plate. Test compounds are preincubated with enzyme by adding together with 40 µl of cell lysate (prepared as above) and 15 incubating for 1 hour at 37° C. at the end of which period 10 µl of 30 µM L-arginine and 0.025 µCi of L-[<sup>3</sup>H]-arginine in 50 mM Tris-HCl is added to start the enzymic reaction. Incubation is continued for a further 1 hour at 37° C. The reaction is terminated by addition of 50 µl of an aqueous 20 solution of 3 mM nitroarginine and 21 mM EDTA.

Labelled L-citrulline is separated from labelled L-arginine using Dowex AG-50W. 120 µl of a 25% aqueous slurry of Dowex 50W is added to 96 well filter plates (0.45 µm pore size). To this is added 120 µl of terminated assay mix. 75 µl 25 of filtrate is sampled and added to the wells of 96 well plates containing solid scintillant. After allowing the samples to dry the L-citrulline is quantified by scintillation counting.

In a typical experiment basal activity is 300 dpm per 75 µl sample of reagent controls, which is increased to 3000 30 dpm in the presence of enzyme. Compound activity is expressed as IC<sub>50</sub> (the concentration of drug substance which gives 50% enzyme inhibition in the assay) and L-NMMA, which gives an IC<sub>50</sub> of about 0.4 µM is tested as a standard to verify the procedure. Compounds are tested at 35 a range of concentrations and from the inhibitions obtained IC<sub>50</sub> values are calculated.

In the above screen the compounds of Examples 1, 3 to 7, 10 to 18, 20 to 23, 27 to 49, 52, 54 to 62, 64 to 67, 69 to 72, 74 to 82, 84 to 88, 90 to 93, 98 to 170, 173 to 180, 182 to 40 242, 245 to 251 and 253 to 257 were tested and gave IC<sub>50</sub> values less than 25 µM, indicating that they are expected to show useful therapeutic activity.

 $R^7$  and  $R^8$  independently represent hydrogen, alkyl C1 to 6 or phenyl optionally substituted by one or more groups selected from alkyl C1 to 6, halogen, cyano, nitro, hydroxyl, alkoxy C1 to 6, trifluoromethyl and trifluoromethoxy; provided that  
 (a) when  $R^3$  and  $R^4$  taken together represent a group  $(CH_2)_a.Z.(CH_2)_b$ , in which Z represents a group  $>NCOX(CH_2)_n.YR^{13}$ , a group  $>NCSX(CH_2)_n.YR^{13}$ , or a group  $>NCNHX(CH_2)_n.YR^{13}$  in which neither X nor Y represents a bond then n represents an integer 2 to 4; and  
 (b) when  $R^3$  and  $R^4$  taken together represent a group  $(CH_2)_a.Z.(CH_2)_b$ , in which Z represents a group  $>NCOX(CH_2)_n.YCN$ , a group  $>NCSX(CH_2)_n.YCN$ , or a group  $>NCNHX(CH_2)_n.YCN$ , then Y represents a bond and either X also represents a bond or X does not represent a bond and n represents an integer 1 to 4;  
 or a pharmaceutically acceptable salt thereof.
