(57) **ABSTRACT**

A cable television system (100) having forward and reverse paths includes, in the reverse path, a digital optical transmitter (200) for receiving an RF signal, converting it to a digital signal, and adding a digital pilot tone thereto. A laser is driven in accordance with the summed digital signal to generate a digital optical signal representative of the pilot tone and the RF signal. The cable television system (100) also includes an optical receiver (305) for receiving the digital optical signal and recovering therefrom the RF signal and the pilot tone. The optical transmitter (200) and receiver (305) are coupled by fiber optic communication media (110).

**DIGITAL OPTICAL TRANSMITTER****FIELD OF THE INVENTION**

This invention relates generally to fiber optic communications, and more specifically to optical transmitters for use in fiber optic communications.

**BACKGROUND OF THE INVENTION**

Cable television systems typically include a headend section for receiving satellite signals and demodulating the signals to baseband. The baseband signal is then converted to an optical signal for transmission from the headend section over fiber optic cable. Optical transmitters are distributed throughout the cable system for splitting and transmitting optical signals, and optical receivers are provided for receiving the optical signals and converting them to radio frequency (RF) signals that are further transmitted along branches of the system over coaxial cable rather than fiber optic cable. Taps are situated along the coaxial cable to tap off the cable signals to subscribers of the system.

Various factors influence the ability to accurately transmit and receive optical signals within a cable television system. As the length of fiber optic cable within a system increases, for example, signal losses also increase. Furthermore, temperature fluctuations, which cause variation in the optical modulation index of the optical transmitter, can result in variation of the radio frequency (RF) output level of the optical receiver. Signal distortions can be caused by nonlinearities in the laser and photodiode of the optical transmitter.

Although these problems can be mitigated by employing expensive techniques, e.g., decreasing fiber lengths between optical nodes, such techniques may prohibitively increase costs to both subscribers and service providers. Thus, what is needed is a better way to provide reliable and accurate transmission of optical signals within a cable television system.

**BRIEF DESCRIPTION OF THE DRAWINGS**

FIG. 1 is a block diagram of a cable television system in accordance with the present invention.

FIG. 2 is an electrical block diagram of an optical transmitter included in the cable television system of FIG. 1 in accordance with the present invention.

FIG. 3 is an electrical block diagram of an optical receiver included in the cable television system of FIG. 1 in accordance with the present invention.

FIG. 4 is a block diagram of a cable television having multiple outputs to subscriber regions in accordance with the present invention.

FIG. 5 is an electrical block diagram of an optical transmitter included in the cable television system of FIG. 4 in accordance with the present invention.

FIG. 6 is an electrical block diagram of an optical receiver included in the cable television system of FIG. 4 in accordance with the present invention.

**DETAILED DESCRIPTION OF A PREFERRED EMBODIMENT**

FIG. 1 shows a communications system, such as a cable television system **100** having both forward and reverse paths, i.e., having the ability to communicate downstream in the forward direction and upstream in the reverse direction. The cable television system **100** includes a headend **105** for

receiving satellite signals that are demodulated to baseband or an intermediate frequency (IF). The baseband signal is then converted to cable television signals that are routed throughout the system **100** to subscriber equipment **130**, such as set top decoders, televisions, or computers, located in the residences or offices of system subscribers. The headend **105** can, for instance, convert the baseband signal to an optical signal that is transmitted over fiber optic cable **110**, in which case a remotely located optical node **115** converts the optical signal to an electrical radio frequency (RF) signal for further transmission through the system **100** over coaxial cable **120**. Taps **125** located along the cable **120** at various points in the distribution system split off portions of the RF signal for routing to subscriber equipment **130** coupled to subscriber drops provided at the taps **125**.

The system **100**, as mentioned, also has reverse transmission capability so that signals, such as data, video, or voice signals, generated by the subscriber equipment **130** can be provided back to the headend **105** for processing. The reverse signals travel through the taps **125** and any nodes **115** and other cable television equipment, e.g., reverse amplifiers, to the headend **105**. In the configuration shown in FIG. 1, RE signals generated by the subscriber equipment **130** travel to the node **115**, which converts the RF signals to optical signals for transmission over the fiber optic cable **110** to the headend **105**.

Referring to FIG. 2, a digital reverse transmitter **200** is provided for transmitting digital optical signals to the headend **105** in the reverse direction. The transmitter **200** can, for instance, be included within the optical node **115**, although other locations within the cable television system **100** may also include the digital reverse transmitter **200** of the present invention. The transmitter **200** receives, at an input **202**, an analog information signal that is representative of one or more reverse RF signals from the subscriber equipment **130**. At its output **204**, the transmitter **200** provides a digital optical signal that is generated in accordance with the analog information signal as well as an optional pilot tone that serves to provide a reference level during processing at the headend **105**.

More specifically, the digital reverse transmitter **200** includes an analog-to-digital (A/D) converter **205** for converting the analog input to a digital signal, i.e., a digital word comprising a particular number of bits, in a conventional manner. The resolution of the A/D converter **205**, of course, is dependent upon transmitter design parameters. The transmitter **200** can also include a digital pilot tone generator **210** for providing a digital pilot tone in the form of a number of bits representative of a particular level and frequency. The digital pilot tone generator **210** could, for instance, include input switches by which the level and frequency could be varied. U.S. Pat. No. 5,563,815 to Jones, the teachings of which are hereby incorporated by reference, shows a digital tone oscillator that could be used to implement the generator **210** included in the transmitter **200** of the present invention.

A summer **215** receives the digital information signal from the A/D converter **205** and the digital pilot tone signal from the generator **210** and digitally adds the two signals by performing binary addition in a known manner. The summed signal is then coupled to a parallel-to-serial (P/S) converter, or a serializer **220**, which receives the parallel inputs representative of the summed signal and converts the inputs into a serial bit stream. A laser diode **225** is then driven to generate an optical signal in accordance with the serial bit stream. It will be appreciated that the serializer **220** can also include a driver for driving the laser diode **225** and frame encoding circuitry for encoding the serialized digital signal into frames of data.

FIG. 3 is a block diagram of an optical receiver 305 for receiving the digital optical signal transmitted by the optical transmitter 200. The receiver 305 can be, for instance, located in the headend 105, although other locations, such as any intervening nodes, may also employ the receiver 305. The receiver 305 includes a detector, such as a photodiode 310, for receiving the digital optical signal transmitted over the fiber optic cable 110 and generating therefrom a serial stream of electrical pulses in accordance with the optical signal. The output signals provided by the photodiode 310 are coupled to a serial-to-parallel (P/S) converter 315 for generating therefrom a set of parallel outputs corresponding to a digital word. The receiver 305 further includes a digital-to-analog (D/A) converter 320 for converting the signal provided at its digital input to an analog signal in a known manner. Thereafter, the analog signal is processed by a filter 325 to separate the pilot tone signal from the information signal. More specifically, the filter 325 preferably comprises a low pass filter that only passes the fundamental frequency component of the output of the D/A converter 320. As a result, the digital optical receiver 305 is able to provide at its output a reference signal, i.e., the pilot tone, and an analog signal that approximates the analog information signal initially provided to the optical transmitter 200. Furthermore, this can be done without encountering many of the problems that arise in prior art designs.

In conventional cable television systems, optical links in the reverse path use amplitude modulation to directly modulate a laser generating a reverse optical signal. As a result, RF output level of the optical receiver is directly dependent upon the optical modulation index (OMI), which in turn is directly related to the RF drive current, the laser threshold current, and the laser bias current of the laser located in the transmitter. Since the laser bias and threshold currents vary with temperature, which in turn causes temperature variations of the OMI, the RF output level of the optical receiver also varies with temperature. However, the laser within the transmitter 200 of the present invention is digitally modulated so that the RF level information is encoded according to a bit stream; as a result, variations in the OMI, the laser bias current, the laser threshold current, and the temperature do not affect RF output levels of the optical receiver 305.

Prior art optical transmission that use AM modulation also result in a system in which the linearity of the received optical signal is directly dependent upon the linearity of the transmitting laser and the receiving photodiode. Therefore, non-linearities of those devices can greatly degrade the performance of the reverse path system. Additionally, the non-linear conversion processes of lasers and photodiodes in conventional systems vary with temperature, thus further degrading the performance. Conversely, the digital optical system, i.e., the digital optical transmitter 200 and the digital optical receiver 305, of the present invention only generates and resolves two amplitude levels rather than a continuum of levels. As a result, linearity requirements of the laser and photodiode are reduced, which results in better performance and less expense.

Another problem associated with conventional cable television systems is that reverse pilot tones are seldom used due to the complications and costs. When such pilot tones are used, an additional oscillator, which is not digital, is generally located outside the transmitter and is susceptible to temperature variations. The oscillator signal is combined with the analog RF signal, and the combined signal is used to modulate the laser diode current to provide an optical output. Prior art pilot tones are used by an optical transmitter to ensure that there is always a minimum RF signal modu-

lating the laser, thereby decreasing the spurious noise generated by the laser, and by an optical receiver for gain control purposes. However, since oscillator output level drifts with temperature, the RF output level of the optical receiver will also drift with temperature so that gain control is essentially useless. As mentioned above, use of the combined digital pilot tone and digital information signal according to the present invention solves the prior art temperature dependency problems. At the same time, the digital pilot tone can be used by the transmitter 200 to modulate the laser even when no RF input is present.

Still another advantage of the digital optical transmitter 200 and receiver 305 of the present invention is that the cable system 100 can, without significant cost or performance penalties, employ an architecture in which fiber stretches deeper into the system 100. As a cable television signal travels along a fiber optic cable 110, the signal decreases in power as a result of laser noise, Rayleigh backscattering, photodiode shot noise, receiver amplifier noise, unmodulated Fabry-Perot sporadic noise, and post amplifier intrinsic noise. These factors cause the carrier-to-noise ratio (CNR) to decrease. Conventionally, this problem is mitigated by driving the transmitter laser with more power and/or increasing the receive sensitivity of the receiver photodiode at great expense. However, this need not be done in a system 100 according to the present invention since the noise sources and corresponding signal degradation resulting from increased fiber lengths does not affect recovery of information to the same extent as in prior art systems.

Referring next to FIG. 4, a modified cable television system 400 is depicted. The system 400 includes a headend 105 for generating cable television signals that are split off to subscriber equipment 130 by taps 125. However, in the system 400, the optical node 415 splits off the downstream cable signal for transmission to multiple distribution systems 430, 435, or branches. Each branch typically provides service to subscribers located in different geographic regions. Upstream reverse signals provided by subscriber equipment 130 in the different branches 430, 435 is transmitted in the form of analog RF signals to the optical node 415, which combines the signals for further upstream transmission in the form of an optical signal. According to the present invention, the upstream signals from the different branches 430, 435 can be converted to a digital optical signal in a manner that minimizes or eliminates many of the problems associated with prior art cable television systems.

FIG. 5 is an electrical block diagram of an optical transmitter 500 that can, in accordance with the present invention, be used to process multiple analog inputs. At input 502, the transmitter 500 receives a first analog input, such as from a first branch 430 of a cable television system 400, and, at input 503, the transmitter 500 receives a second analog input, such as from a second branch 435 of the system 400. First and second A/D converters 205, 505 respectively convert the received RF signals to digital information signals that are separately summed, by summers 215, 515, with the digital pilot tone. Each summed signal is then serialized by serializers 220, 520 to result in first and second serial bit streams that are representative of the first and second RF signals, respectively, as separately combined with the digital pilot tone. According to the present invention, bits of the serial bit streams are interleaved by an interleaver 550 to form a single digital signal that modulates the laser diode 225. As a result, a single digital optical signal can be provided at the output 504 of the transmitter 500.

Referring to FIG. 6, an optical receiver 605 for processing the digital optical signal generated by the transmitter 500 is

shown. The receiver **605** includes a photodiode **310** for generating electrical pulses from the optical signal and a deinterleaver **650** for deinterleaving the signal comprising the electrical pulses. Once the deinterleaver **650** has separated the received signal into separate serial bit streams, the outputs are coupled to first and second S/P converters **315**, **615**, first and second D/A converters **320**, **620**, and first and second filters **325**, **625** to recover approximations of the pilot tone and the RF signals that were provided to the transmitter **500**.

It will be appreciated that the interleaver **550** and the deinterleaver **650** can be implemented using conventional components. Typically, the interleaver **550** could be a framing device capable of implementing a time-domain-multiplexing (TDM) scheme with respect to the incoming bit streams. In such an implementation, a frame clock (not shown) would be coupled to the interleaver **550**, and one frame would consist of a number of sub-frames equivalent to the number of incoming bit streams. A flag bit would likely be inserted into the frame for identifying the start of the frame. The deinterleaver **650** is capable of extracting the frame clock signal from the incoming information and recognizing the flag bits indicative of frame starts. Each bit would then be routed to its respective bit stream to recover the original signals.

Although only two input branches into the transmitter **500** and two processing paths through the transmitter **500** and the receiver **605** are shown, a plurality of paths can be provided depending upon the number of incoming analog signals to be processed by the transmitter **500**. For example, if five RF signals are traveling in the reverse paths of five branches of a cable television system, the optical transmission system according to the present invention would individually convert each reverse signal to a digital signal, add it to the pilot tone, and serialize the combined signal. All serialized signals would then be combined by the interleaver **550** to generate a bit stream for modulating the laser diode **225** (FIG. 5). On the receiver end, the deinterleaver **650** would deinterleave the received digital optical signal to provide five serial signals that would be individually processed by S/P converters, D/A converters, and filters to provide five analog outputs as well as an approximation of the pilot tone.

In this manner, reverse signals of the same frequency can be conveniently sent to the headend **105** over the same return fiber **110**. This is very important since cable television systems typically only allocate a small amount of bandwidth, e.g., 5–40 MHz, for return path transmissions, which means that varying the frequency of each return path signal would not be practical.

In summary, the reverse digital transmission system described above provides one or more reverse signals without many of the problems present in prior art systems. As a result, information can be sent from subscribers to the headend in a more reliable and less expensive manner.

What is claimed is:

1. A cable television system having forward and reverse paths for respectively transmitting forward and reverse signals, the cable television system comprising:

- first and second distribution systems for providing information to system subscribers located, respectively, in first and second geographic regions;
- a headend for generating and transmitting optical signals;

an optical node, remotely located from the headend, for converting the optical signals to electrical signals and for transmitting the electrical signals over the first and second distribution systems, wherein, in the reverse path, the optical node comprises an optical transmitter, including:

- a first A/D converter for receiving a first analog information signal from subscriber equipment included in the first distribution system and converting the first analog information signal to a first digital information signal;
- a second A/D converter for receiving a second analog information signal from subscriber equipment included in the second distribution system and converting the second analog information signal to a second digital information signal;
- a digital pilot tone generator for generating a digital pilot tone;
- summers coupled to the first and second A/D converters and the digital pilot tone generator for adding the digital pilot tone to the first digital information signal to result in a first summed signal and for adding the digital pilot tone to the second digital information signal to result in a second summed signal;
- serializers coupled to the summers to convert the first and second summed signals to first and second serial signals;
- an interleaver coupled to the serializers for interleaving bits of the first summed signal with bits of the second summed signal to generate an interleaved signal; and
- a laser diode coupled to the interleaver for emitting a digital optical signal in accordance with the interleaved signal.

2. In a communications system having forward and reverse paths for respectively transmitting forward and reverse signals from a headend, the communications system including first and second distribution systems for providing information to system subscribers located, respectively, in first and second geographic regions, the reverse path comprising:

- an optical transmitter, comprising:
  - a first analog-to-digital (AID) converter for receiving a first reverse analog signal from subscriber equipment in the first distribution system and for converting the first reverse analog signal to a first reverse digital signal;
  - a second A/D converter for receiving a second reverse analog signal from subscriber equipment in the second distribution system and for converting the second reverse analog signal to a second reverse digital signal;
  - a digital pilot tone generator for generating a digital pilot tone;
  - coupled to the first and second A/D converters and the digital pilot tone generator for adding the digital pilot tone to the first reverse digital signal to result in a first summed signal and for adding the digital pilot tone to the second reverse digital signal to result in a second summed signal;
  - serializers coupled to the summers for framing the first summed signal and the second summed signal, and for providing a first and second serial reverse digital signal;
  - an interleaver coupled to the serializers for interleaving bits of the first summed signal with bits of the second summed signal to generate an interleaved signal;

**7**

a laser diode coupled to the interleaver for emitting a digital optical signal in accordance with the interleaved signal; and  
an optical receiver coupled to the optical transmitter via a communication medium, comprising:  
a photodiode for converting the digital optical signal to the interleaved signal;  
a deinterleaver for deinterleaving the interleaved signal into the first and second reverse digital signal;  
deserializers for deserializing the first and second reverse digital signal; and

**8**

a first digital-to-analog (D/A) converter for recovering the first reverse analog signal from the first reverse digital signal; and  
a second D/A converter for recovering the second reverse analog signal from the second reverse digital signal.  
**3.** The communications system of claim **2**, wherein the digital pilot tone provides a reference level for processing in the headend, and wherein the digital pilot tone is not affected by surrounding temperature.
