**4-OXO-1,4-DIHYDRO-3-CINNOLINECARBOXAMIDES AS ANTIVIRAL AGENTS**

**CROSS REFERENCE TO RELATED APPLICATIONS**

This application claims the benefit of the following provisional application: U.S. Serial No. 60/191,291, filed Mar. 21, 2000.

**BACKGROUND OF THE INVENTION**

**1. Field of the Invention**

The present invention provides novel cinnolines, which are useful as antiviral agents (e.g. as agents against viruses of the herpes family).

**2. Technology Description**

The herpesviruses comprise a large family of double stranded DNA viruses. They are also a source of the most common viral illnesses in man. Eight of the herpes viruses, herpes simplex virus types 1 and 2 (HSV-1 and HSV-2), varicella zoster virus (VZV), human cytomegalovirus (HCMV), epstein-Barr virus (EBV), and human herpes viruses 6, 7, and 8 (HHV-6, HHV-7, and HHV-8), have been shown to infect humans.

HSV-1 and HSV-2 cause herpetic lesions on the lips and genitals, respectively. They also occasionally cause infections of the eye and encephalitis. HCMV causes birth defects in infants and a variety of diseases in immunocompromised patients such as retinitis, pneumonia, and gastrointestinal disease. VZV is the causative agent of chicken pox and shingles. EBV causes infections mononucleosis. It can also cause lymphomas in immunocompromised patients and has been associated with Burkitt's lymphoma, nasopharyngeal carcinoma, and Hodgkins disease. HHV-6 is the causative agent of roseola and may be associated with multiple sclerosis and chronic fatigue syndrome. HHV-7 disease association is unclear, but it may be involved in some cases of roseola. HHV-8 has been associated with Kaposi's sarcoma, body cavity based lymphomas, and multiple myeloma.

U.S. Pat. No. 4,826,837 discloses 4-hydroxycinnoline-3-carboxamides and their use for the treatment of neoplastic diseases and acute and chronic infections of both bacterial and viral origin in mammals.

U.S. Pat. No. 4,886,800 discloses 4-substituted-cinnoline-3-carboxylic acids and 3-acyl-4-substituted-cinnoline derivatives and their use as central nervous system depressants.

U.S. Pat. Nos. 5,753,666 and 5,891,878 and WO 97/04775 disclose 1-alkyl-substituted-quinolone-3-carboxamides that are alleged to have therapeutic utility via inhibition of Phosphodiesterase IV esterase and/or Tumor Necrosis factor activity.

WO 99/38867 discloses 1-cycloalkyl-1,8-naphthyridin-4-one derivatives; pharmacologically acceptable salts or solvates thereof; and a phosphodiesterase IV inhibitor containing any of the above as an active ingredient.

Commonly assigned PCT/US98/25192 discloses 4-hydroxyquinoline-3-carboxamides and hydrazides as antiviral agents.

Despite the above teachings, there still exists a need in the art for novel compounds that demonstrate desirable antiviral activity.

**BRIEF SUMMARY OF THE INVENTION**

In accordance with the present invention, novel compounds which demonstrate antiviral activity are provided.

#### DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

65 In describing the preferred embodiment, certain terminology will be utilized for the sake of clarity. Such terminology

is intended to encompass the recited embodiment, as well as all technical equivalents which operate in a similar manner for a similar purpose to achieve a similar result.

### 1. Terminology Definitions

The following definitions are used, unless otherwise described: halo is fluoro, chloro, bromo, or iodo. Alkyl denotes both straight and branched groups; but reference to an individual radical such as "propyl" embraces only the straight chain radical, a branched chain isomer such as "isopropyl" being specifically referred to. When alkyl can be partially unsaturated, the alkyl chain may comprise one or more (e.g. 1, 2, 3, or 4) double or triple bonds in the chain.

Aryl denotes a phenyl radical or an ortho-fused bicyclic carbocyclic radical wherein at least one ring is aromatic. Het is a four-(4), five-(5), six-(6), or seven-(7) membered saturated or unsaturated ring containing 1, 2 or 3 heteroatoms selected from the group consisting of non-peroxide oxygen, sulfur, and nitrogen, which is optionally fused to a benzene ring, or any bicyclic heterocyclic group. Het includes "heteroaryl," which encompasses a radical attached via a ring carbon of a monocyclic aromatic ring containing five or six ring atoms consisting of carbon and 1, 2, 3, or 4 heteroatoms each selected from the group consisting of non-peroxide oxygen, sulfur, and N(X) wherein X is absent or is H, O, C<sub>1-4</sub>alkyl, phenyl or benzyl.

It will be appreciated by those skilled in the art that compounds of the invention having a chiral center may exist in and be isolated in optically active and racemic forms. Some compounds may exhibit polymorphism. It is to be understood that the present invention encompasses any racemic, optically-active, polymorphic, tautomeric, or stereoisomeric form, or mixture thereof, of a compound of the invention, which possesses the useful properties described herein, it being well known in the art how to prepare optically active forms (for example, by resolution of the racemic form by recrystallization techniques, by synthesis from optically-active starting materials, by chiral synthesis, or by chromatographic separation using a chiral stationary phase) and how to determine antiviral activity using the standard tests described herein, or using other similar tests which are well known in the art.

To the extent that any pharmaceutically active compound is disclosed or claimed, it is expressly intended to include all active metabolites produced in vivo.

The carbon atom content of various hydrocarbon-containing moieties is indicated by a prefix designating a lower and upper number of carbon atoms in the moiety, i.e., the prefix C<sub>i-j</sub> indicates a moiety of the integer "i" to the integer "j" carbon atoms, inclusive. Thus, for example, C<sub>1-7</sub>alkyl refers to alkyl of one to seven carbon atoms, inclusive.

The compounds of the present invention are generally named according to the IUPAC or CAS nomenclature system. Abbreviations which are well known to one of ordinary skill in the art may be used (e.g. "Ph" for phenyl, "Me" for methyl, "Et" for ethyl, "h" for hour or hours and "rt" for room temperature).

Specific and preferred values listed below for radicals, substituents, and ranges, are for illustration only; they do not exclude other defined values or other values within defined ranges for the radicals and substituents. The compounds of the invention include compounds of formula (I) or (II) having any combination of the values, specific values, more specific values, and preferred values described herein.

The following Charts A–O describe the preparation of the compounds of the present invention. All of the starting materials and final compounds are prepared by procedures described in these charts or by procedures analogous thereto, which would be well known to one of ordinary skill in organic chemistry. All of the variables used in the charts are as defined below or as in the claims.

The general ring system can be prepared in several ways. An example of the first route is shown in Chart A. Carboxylation of 4-fluoro-1-iodobenzene (X=H, Y=I) by treatment with a base such as lithium diisopropylamide followed by quenching with CO<sub>2</sub> provides the alpha-fluorocarboxylic acid A-2. This can be elaborated to the beta-ketoester by activation of the acid with a condensing agent such as 1,1'-carbonyldiimidazole, and displacement with the TMS ester of ethyl malonate. Diazotization, reduction and cyclization provides the 4-hydroxycinnoline-3-carboxylic ester (*Chem Pharm Bull*, 1988, 38, 1321). Treatment with an amine such as 4-chlorobenzylamine at elevated temperature provides the 4-hydroxycinnoline-3-carboxamide.

**13**  
Chart A

The requisite beta-ketoesters A-3 can be prepared by several different methods, one of which is shown in Chart B. Reductive amination of 3-bromo-4-fluorobenzaldehyde with an amine such as morpholine provides the substituted benzene B-2. Metallation with n-BuLi and trapping N-methoxy-N-methylacetamide will give the ketone B-3 which can be elaborated to the beta-ketoester by treatment with sodium hydride and diethyl carbonate.

Alternatively, the fluorobenzene C-2 can be directly lithiated with lithium diisopropylamide. Trapping of the resulting anion with an electrophile such as iodine followed by a subsequent deprotonation and trapping with CO<sub>2</sub> will provide the disubstituted acid C-4. This again can be elaborated to the beta-ketoester by activation of the acid with a condensing agent such as 1,1'-carbonyldiimidazole and displacement with the TMS ester of ethyl malonate.

The cinnoline ring system can be prepared as shown in Chart D. Diazotization of an aniline followed by treatment with diethyl malonate provides the cyclization precursor. Cyclization is then effected by hydrolysis to the diacid, treatment with thionyl chloride to form the diacid chloride and cyclization promoted by  $\text{TiCl}_4$  (*J. Chem. Soc.* 1961, 2828–2843). The resulting cinnoline 3-carboxylic acid can then be condensed with an amine such as 4-chlorobenzylamine by activation of the acid with a condensing agent such as 1,1'-carbonyldiimidazole and subsequent coupling of the activated acid with the desired amine.

The requisite anilines for the above synthesis can be obtained from commercial sources, prepared according to literature procedures or further functionalized, an example of which is shown in Chart E. Iodination of the aniline can be accomplished by treatment with an appropriate iodinating agent, such as  $\text{ICl}$ .

Chart D

Chart E

The cinnolines (A-6 or D-6 or O-6) can be alkylated by treatment with an alkylating agent such as methyl iodide and potassium carbonate in a DMF solution or by treatment with a base such as sodium hydride or lithium bis(trimethylsilyl) amide followed by treatment with an alkylating agent. Alternatively, the compounds may be alkylated on nitrogen under Mitsunobu conditions using reagents such as triphenylphosphine, diethyl azodicarboxylate and an appropriate alcohol such as methanol (Chart F).

Chart F

17

-continued

The substituted cinnolines can be further elaborated. One such elaboration is a palladium-catalyzed coupling of compounds such as F-1 where Y=I with acetylenes such as propargyl alcohol shown in Chart G. Reduction of the alkyne by hydrogenation in the presence of an appropriate catalyst such as palladium or platinum gives the corresponding alkane G-2.

Chart G

A second example of elaboration of the cinnoline substitution is the preparation of the hydroxymethyl substituted cinnoline shown in Chart H. Palladium catalyzed carbomethylation of the cinnoline ring system (F-1 where X=I) provides the methyl ester H-1. Reduction of the ester provides the 6-hydroxymethyl substituted cinnoline. This can be alkylated on nitrogen by treatment with an alkylating agent such as methyl iodide and potassium carbonate in a DMF solution.

18

Chart H

Alcohols such as the one depicted in Chart H can be further elaborated as shown in Chart I by activation with reagents such as methanesulfonyl chloride and displacement with nucleophiles such as thiols or amines (e.g. morpholine).

Chart I

The compounds prepared as in Chart F can be further elaborated. One example of such an elaboration is shown in Chart J. Compound F-1 (where Y=morpholinylmethyl and X=I) can undergo palladium-catalyzed coupling with acetylenes to produce compounds such as J-1. Hydrogenation with an appropriate catalyst such as palladium on carbon would provide compounds such as J-2.

25 The requisite ester K-1 can be prepared by alkylation of  
 30 the ester A-5 with an appropriate alkylating agent such as  
 methyl iodide with an appropriate base such as K<sub>2</sub>CO<sub>3</sub> or by  
 treatment with a base such as sodium hydride followed by  
 treatment with an alkylating agent such as methyl iodide as  
 shown in Chart L.

35 Another example of a further manipulation of the cinnolines  
 is shown in Chart K. Treatment of the ester K-1 with  
 lithium bis(trimethylsilyl)amide and copper iodide followed  
 by treatment with methanol will give the corresponding  
 aminocinnoline K-2 (*JCS Chem Comm*, 1974, 256). Amide  
 formation by treatment with an amine such as  
 4-chlorobenzylamine followed by reductive amination with  
 an aldehyde or ketone will give the amino-substituted com-  
 40 pounds K-3.

Chart K

Chart L

55 Further functionalization of the cinnoline nucleus can also  
 60 be accomplished as shown in Chart M. Palladium-catalyzed  
 carbonylation of the cinnoline F-1 (where X=I) in the  
 presence of a silane such as trioctylsilane or tributyltin  
 hydride will give the aldehyde M-1. Reductive aminations  
 65 with primary or secondary amines in the presence of sodium  
 triacetoxyborohydride will give the aminomethyl deriva-  
 tives M-2.

21

Chart M

An additional example of further functionalization of the substituted cinnolines is shown in Chart N. Reduction of the aldehyde M-1 with a reagent such as sodium borohydride followed by acylation of the resulting alcohol will provide esters and carbamates N-2.

Chart N

-continued

Another alternative route to the cinnoline ring system is outlined in Chart O. The key step in this sequence involves the diazotization and cyclization of an ortho-alkynyl aniline O-3 to generate the 4-hydroxy-3-substituted cinnoline O-4 (*Leibigs Ann.* 1995, 775-779). The ortho-alkynyl aniline O-3 can be obtained from a 4-substituted aniline via bisiodination and cross-coupling with an alkyne. Deprotection of O-4 followed by oxidation utilizing an oxidizing agent such as pyridinium dichromate or a two step procedure employing reagents such as IBX followed by NaClO<sub>2</sub> would provide the acid O-5. The resulting cinnoline 3-carboxylic acid can then be condensed with an amine such as 4-chlorobenzylamine by activation of the acid with a condensing agent such as 1,1'-carbonyldiimidazole and subsequent coupling of the activated acid with the desired amine.

The inventive compounds may be used in their native form or as salts. In cases where compounds are sufficiently basic or acidic to form stable nontoxic acid or base salts, administration of the compounds as salts may be appropriate. Examples of pharmaceutically acceptable salts are organic acid addition salts formed with acids that form a physiological acceptable anion, for example, tosylate, methanesulfonate, acetate, citrate, malonate, tartarate, succinate, benzoate, ascorbate, ( $\alpha$ -ketoglutarate, and ( $\alpha$ -glycerophosphate. Suitable inorganic salts may also be formed, including hydrochloride, sulfate, nitrate, bicarbonate, and carbonate salts.

Pharmaceutically acceptable salts may be obtained using standard procedures well known in the art, for example by reacting a sufficiently basic compound such as an amine with a suitable acid affording a physiologically acceptable anion. Alkali metal (for example, sodium, potassium or lithium) or alkaline earth metal (for example calcium) salts of carboxylic acids can also be made.

Compounds of the present invention can conveniently be administered in a pharmaceutical composition containing the compound in combination with a suitable excipient, the composition being useful in combating viral infections. Pharmaceutical compositions containing a compound appropriate for antiviral use are prepared by methods and contain excipients which are well known in the art. A generally recognized compendium of such methods and ingredients is Remington's Pharmaceutical Sciences by E. W. Martin (Mark Publ. Co., 15th Ed., 1975). To the extent necessary for completion, this publication is expressly incorporated by reference. The compounds and compositions of the present invention can be administered parenterally (for example, by intravenous, intraperitoneal or intramuscular injection), topically, intranasally, intravaginally, orally, or rectally, depending on whether the preparation is used to treat internal or external viral infections.

For oral therapeutic administration, the active compound may be combined with one or more excipients and used in the form of ingestible tablets, buccal tablets, troches, capsules, elixirs, suspensions, syrups, wafers, and the like. Such compositions and preparations should contain at least 0.1% of active compound. The percentage of the compositions and preparations may, of course, be varied and may conveniently be between about 2 to about 60% of the weight of a given unit dosage form. The amount of active compound in such therapeutically useful compositions is such that an effective dosage level will be obtained.

The tablets, troches, pills, capsules, and the like may also contain the following: binders such as gum tragacanth, acacia, corn starch or gelatin; excipients such as dicalcium phosphate; a disintegrating agent such as corn starch, potato starch, alginic acid and the like; a lubricant such as magnesium stearate; and a sweetening agent such as sucrose, fructose, lactose or aspartame or a flavoring agent such as peppermint, oil of wintergreen, or cherry flavoring may be

24

added. When the unit dosage form is a capsule, it may contain, in addition to materials of the above type, a liquid carrier, such as a vegetable oil or a polyethylene glycol. Various other materials may be present as coatings or to otherwise modify the physical form of the solid unit dosage form. For instance, tablets, pills, or capsules may be coated with gelatin, wax, shellac or sugar and the like. A syrup or elixir may contain the active compound, sucrose or fructose as a sweetening agent, methyl and propylparabens as preservatives, a dye and flavoring such as cherry or orange flavor. Of course, any material used in preparing any unit dosage form should be pharmaceutically acceptable and substantially non-toxic in the amounts employed. In addition, the active compound may be incorporated into sustained-release preparations and devices such as those which rely on osmotic delivery sold by Alza Corporation under the OROS trademark.

The compounds or compositions can also be administered intravenously or intraperitoneally by infusion or injection. Solutions of the active compound or its salts can be prepared in water, optionally mixed with a nontoxic surfactant. Dispersions can also be prepared in glycerol, liquid polyethylene glycols, triacetin, cyclodextrins and mixtures thereof and in oils. Under ordinary conditions of storage and use, these preparations contain a preservative to prevent the growth of microorganisms.

Pharmaceutical dosage forms suitable for injection or infusion can include sterile aqueous solutions or dispersions or sterile powders comprising the active ingredient which are adapted for the extemporaneous preparation of sterile injectable or infusible solutions or dispersions, optionally encapsulated in liposomes. In all cases, the ultimate dosage form should be sterile, fluid and stable under the conditions of manufacture and storage. The liquid carrier or vehicle can be a solvent or liquid dispersion medium comprising, for example, water, ethanol, a polyol (for example, glycerol, propylene glycol, liquid polyethylene glycols, and the like), vegetable oils, nontoxic glyceryl esters, and suitable mixtures thereof. The proper fluidity can be maintained, for example, by the formation of liposomes, by the maintenance of the required particle size in the case of dispersions or by the use of surfactants. The prevention of the action of microorganisms can be brought about by various antibacterial and antifungal agents, for example, parabens, chlorobutanol, phenol, sorbic acid, thimerosal, and the like. In many cases, it will be preferable to include isotonic agents, for example, sugars, buffers or sodium chloride. Prolonged absorption of the injectable compositions can be brought about by the use in the compositions of agents delaying absorption, for example, aluminum monostearate and gelatin.

Sterile injectable solutions can be prepared by incorporating the active compound in the required amount in the appropriate solvent with various of the other ingredients enumerated above, as required, followed by filter sterilization. In the case of sterile powders for the preparation of sterile injectable solutions, the preferred methods of preparation are vacuum drying and the freeze drying techniques, which yield a powder of the active ingredient plus any additional desired ingredient present in the previously sterile-filtered solutions.

For topical administration, the present compounds may be applied in pure form, i.e., when they are liquids. However, it will generally be desirable to administer them to the skin as compositions or formulations, in combination with a dermatologically acceptable carrier, which may be a solid or a liquid.

Useful solid carriers include finely divided solids such as talc, clay, microcrystalline cellulose, silica, alumina and the like. Useful liquid carriers include water, alcohols or glycols or water-alcohol/glycol blends, in which the present compounds can be dissolved or dispersed at effective levels, optionally with the aid of non-toxic surfactants. Adjuvants such as fragrances and additional antimicrobial agents can be added to optimize the properties for a given use. The resultant liquid compositions can be applied from absorbent pads, used to impregnate bandages and other dressings, or sprayed onto the affected area using pump-type or aerosol sprayers. Thickeners such as synthetic polymers, fatty acids, fatty acid salts and esters, fatty alcohols, modified celluloses or modified mineral materials can also be employed with liquid carriers to form spreadable pastes, gels, ointments, soaps, and the like, for application directly to the skin of the user.

Examples of useful dermatological compositions which can be used to deliver the compounds of formula I to the skin are known to the art; for example, see Jacquet et al. (U.S. Pat. No. 4,608,392), Geria (U.S. Pat. No. 4,992,478), Smith et al. (U.S. Pat. No. 4,559,157) and Wortzman (U.S. Pat. No. 4,820,508).

Useful dosages of the compounds of formula I can be determined by comparing their in vitro activity, and in vivo activity in animal models. Methods for the extrapolation of effective dosages in mice, and other animals, to humans are known to the art; for example, see U.S. Pat. No. 4,938,949.

The compound is conveniently administered in unit dosage form; for example, containing 5 to 1000 mg, conveniently 10 to 750 mg, most conveniently, 50 to 500 mg of active ingredient per unit dosage form. The desired dose may conveniently be presented in a single dose or as divided doses administered at appropriate intervals, for example, as two, three, four or more sub-doses per day. The sub-dose itself may be further divided, e.g., into a number of discrete loosely spaced administrations; such as multiple inhalations from an insufflator or by application of a plurality of drops into the eye.

For internal infections, the compositions can be administered orally or parenterally at dose levels, calculated as the free base, of about 0.1 to 300 mg/kg, preferably 1.0 to 30 mg/kg of mammal body weight, and can be used in man in a unit dosage form, administered one to four times daily in the amount of 1 to 1000 mg per unit dose.

For parenteral administration or for administration as drops, as for eye infections, the compounds are presented in aqueous solution in a concentration of from about 0.1 to about 10%, more preferably about 0.1 to about 7%. The solution may contain other ingredients, such as emulsifiers, antioxidants or buffers.

Generally, the concentration of the compound(s) of formula I in a liquid composition, such as a lotion, will be from about 0.1–25 wt-%, preferably from about 0.5–10 wt-%. The concentration in a semi-solid or solid composition such as a gel or a powder will be about 0.1–5 wt-%, preferably about 0.5–2.5 wt-%.

The exact regimen for administration of the compounds and compositions disclosed herein will necessarily be dependent upon the needs of the individual subject being treated, the type of treatment and, of course, the judgment of the attending practitioner. The compounds of the present invention can be administered to an animal in need of treatment. In most instances, this will be a human being, but the treatment of livestock (e.g.: cows, pigs, goats, sheep, deer, etc.) and companion animals (e.g. dogs, cats, fish,

horses and birds) is also specifically contemplated as falling within the scope of the instant invention.

The invention will be further described by the following non-limiting examples.

#### Preparation 1

##### 2-fluoro-5-iodobenzoic acid

To a  $-78^{\circ}\text{C}$ . solution of  $i\text{Pr}_2\text{NH}$  (16.80 mL) in 200 mL freshly distilled THF is added  $n$ -butyllithium (68 mL) dropwise, maintaining the temperature of the reaction below  $-65^{\circ}\text{C}$ . The reaction is stirred for 10 minutes, then 1-fluoro-4-iodobenzene (11.50 mL) as a solution in 10 mL THF is added over 20 minutes. The reaction is stirred at  $-78^{\circ}\text{C}$ . or 90 minutes, then cannulated rapidly into diethyl ether (180 mL) and dry ice (approximately 75 g). The reaction is stirred at room temperature overnight. To the ether solution is added 1N NaOH (100 mL) and water (200 mL) and the solution placed in a separatory funnel. The aqueous layer is removed. The organic layer is washed with  $\text{H}_2\text{O}$  ( $2\times 100$  mL). All the aqueous portions are combined, chilled in ice/ $\text{H}_2\text{O}$ , and acidified to pH 2 with 6N HCl. This solution is then extracted with diethyl ether ( $2\times 200$  mL). The ether portions are combined, dried over  $\text{Na}_2\text{SO}_4$ , filtered, and concentrated to give a pale yellow solid. The solid is dissolved in a minimal amount of EtOAc on the steam bath, and hexanes are added to affect recrystallization. After standing in the freezer overnight, the product is obtained as a crystalline white solid (15.44 g, 58%). Physical characteristics are as follows: m.p.  $157$ – $159^{\circ}\text{C}$ .;  $^1\text{H}$  NMR (300 MHz,  $\text{CDCl}_3$ )  $\delta$  8.34, 7.88, 6.97; IR (drift) 3098, 3079, 3051, 3017, 3007, 2998, 2981, 2971, 2881, 2817, 1708, 1681, 1300, 1236,  $824\text{ cm}^{-1}$ ; Anal. #### Preparation 2

##### Ethyl 3-(2-fluoro-5-iodophenyl)-3-oxopropanoate

To a solution of 2-fluoro-5-iodobenzoic acid (Prep. 1, 4.03 g) in 11 mL freshly distilled THF is added 1,1-carbonyldiimidazole (CDI) (2.96 g) in small portions. Vigorous gas evolution is observed. The reaction is stirred overnight. In a separate flask, ethyl malonate potassium salt (2.84 g) is suspended in 10 mL  $\text{CH}_3\text{CN}$ . To this solution is added chlorotrimethylsilane (2.15 mL) and the reaction is stirred at room temperature overnight. The latter reaction is cooled to  $0^{\circ}\text{C}$ . and DBU (5.00 mL) is added dropwise. This reaction is stirred at  $0^{\circ}\text{C}$ . for 3 h. The solution of the CDI adduct is then cannulated over and the mixture is stirred at  $0^{\circ}\text{C}$ . for 2 h. Upon complete conversion to product as

## Testing of Inventive Compounds

The antiviral activity of a compound of the invention can be determined using pharmacological models which are well known to the art, or using Test A described below.

The compounds of formula (I) and pharmaceutically acceptable salts thereof are useful as antiviral agents. Thus, they are useful to combat viral infections in animals, including man. The compounds are generally active against herpes viruses, and are particularly useful against the varicella zoster virus (VZV), the Epstein-Barr virus, the herpes simplex virus, the human herpes virus type 8 (HHV-8) and the cytomegalovirus (CMV).

While many of the compounds of the present invention have shown activity against the CMV polymerase, these compounds may be active against the cytomegalovirus by this or other mechanisms of action. Thus, the description below of these compounds' activity against the CMV polymerase is not meant to limit the present invention to a specific mechanism of action.

## Test A

The HCMV polymerase assay is performed using a scintillation proximity assay (SPA) as described in several references, such as N. D. Cook, et al., *Pharmaceutical Manufacturing International*, pages 49-53 (1992); K. Takeuchi, *Laboratory Practice*, September issue (1992); U.S. Pat. No. 4,568,649 (1986); which are incorporated by reference herein. Reactions are performed in 96-well plates. The assay is conducted in 100  $\mu$ l volume with 5.4 mM HEPES (pH 7.5), 11.7 mM KCl, 4.5 mM MgCl<sub>2</sub>, 0.36 mg/ml BSA, and 90 nM <sup>3</sup>H-dTTP. Assays are run with and without CHAPS, (3-[(3-cholamidopropyl)-dimethylammonio]-1-propane-sulfonate) at a final concentration of 2 mM. HCMV polymerase is diluted in enzyme dilution buffer containing

36

50% glycerol, 250 mM NaCl, 10 mM HEPES (pH 7.5), 100  $\mu$ g/ml BSA, and 0.01% sodium azide. The HCMV polymerase, which is expressed in recombinant baculovirus-infected SF-9 cells and purified according to literature procedures, is added at 10% (or 10  $\mu$ l) of the final reaction volume, i.e., 100  $\mu$ l. Compounds are diluted in 50% DMSO and 10  $\mu$ l are added to each well. Control wells contain an equivalent concentration of DMSO. Unless noted otherwise, reactions are initiated via the addition of 6 nM biotinylated poly(dA)-oligo(dT) template/primer to reaction mixtures containing the enzyme, substrate, and compounds of interest. Plates are incubated in a 25° C. or 37° C. H<sub>2</sub>O bath and terminated via the addition of 40  $\mu$ l/reaction of 0.5 M EDTA (pH 8) per well. Reactions are terminated within the time-frame during which substrate incorporation is linear and varied depending upon the enzyme and conditions used, i.e., 30 min. for HCMV polymerase. Ten  $\mu$ l of streptavidin-SPA beads (20 mg/ml in PBS/10% glycerol) are added following termination of the reaction. Plates are incubated 10 min. at 37° C., then equilibrated to room temperature, and counted on a Packard Topcount. Linear regressions are performed and IC<sub>50</sub>'s are calculated using computer software.

A modified version of the above HCMV polymerase assay is performed as described above, but with the following changes: Compounds are diluted in 100% DMSO until final dilution into assay buffer. In the previous assay, compounds are diluted in 50% DMSO. 4.5 mM dithiothreitol (DTT) is added to the polymerase buffer. Also, a different lot of CMV polymerase is used, which appears to be more active resulting in a more rapid polymerase reaction. Results of the testing of representative compounds of formula I in this assay are shown in Table 1. All results are listed as Polymerase IC<sub>50</sub> ( $\mu$ M) values. In Table 1, the term "nd" refers to activity data not determined.

Example	HCMV	HSV	VZV
1	5.5	nd	nd
2	2.7	1.7	1.1
3	9.8	nd	nd
4	16.7	nd	nd
5	1.2	nd	nd
