(57) **ABSTRACT**

The present invention provides a tablet packing apparatus which is possible to feed specially administrative tablets separately from general tablets. Specially administrative tablets are contained in a feeder vessel. A tablet reserving member **200** is disposed below the feeder vessel **36**. A shutter **203** which is movable to open and close the lower opening of the tablet reserving member **200** is provided. When setting the tablet vessel beneath the tablet reserving member **200** and moving the shutter **203** to open the lower opening of the tablet reserving member **200**, the specially administrative tablets are fed into the tablet vessel without passing through the common passage.

TABLET PACKING APPARATUS

BACKGROUND OF THE INVENTION

1. Field of the Invention

The present invention relates to a tablet packing apparatus and more particularly to a tablet packing apparatus which is suited to feed specially administrative tablets (for example, pyrine medicine) to a tablet vessel.

2. Description of Related Art

Conventionally, there has been known a tablet packing apparatus in which tablets stored in a tablet feed section are fed through a common passage and contained in a tablet vessel fed from a tablet vessel feed section.

However, in the tablet packing apparatus, even specially administrative tablets such as pyrine medicines and histamine tablets which cause allergy or so to some patients are conveyed through the common passage. Thus, dust from the specially administrative tablets remain on the common passage, allowing the dust to adhere to the surface of other general tablets which are conveyed through the common passage.

SUMMARY OF THE INVENTION

It is an object of the present invention to provide a tablet packing apparatus in which it is possible to feed specially administrative tablets separately from general tablets.

The present invention provides, as a solution to the above-described problems with the prior art, a tablet packing apparatus in which tablets fed from a plurality of feeder vessels in a tablet feed section through a common passage are contained in a tablet vessel fed from a tablet vessel feed section. The apparatus includes:

a tablet reserving member disposed below the feeder vessel which stores specially administrative tablets, the tablet reserving member having a lower opening, the tablet reserving member receiving the specially administrative tablets fed from the feeder vessel; and

a shutter which is movable to open and close the lower opening of the tablet reserving member, whereby when setting the tablet vessel beneath the tablet reserving member and moving the shutter to open the lower opening of the tablet reserving member, the specially administrative tablets are fed into the tablet vessel without passing through the common passage.

According to the present invention, the specially administrative tablets such as pyrine medicines and histamine tablets are contained in the tablet reserving member and then fed into the tablet vessel without passing through the common passage. Thus, dust generated during conveyance of the specially administrative tablets do not adhere to the other general tablets which pass through the common passage.

It is preferable that the tablet reserving member is separated from the feeder vessel and connected to the feeder vessel by means of a tube. Thus, it is possible to select a place where the specially administrative tablets are fed from the tablet reserving member. It is also possible to dispose the tablet reserving member at a desired place, resulting in effective dispensing work of the specially administrative tablets.

It is preferable that the tablet reserving member includes a biasing member for biasing the shutter so as to close the lower opening of the tablet reserving member and the shutter is formed with a cutout portion with which the tablet vessel engages, whereby when engaging the tablet vessel with the cutout portion to push the shutter, the shutter opens the lower opening of the tablet reserving member. Thus, it is possible to easily position the tablet vessel beneath the tablet reserving member and smoothly open the shutter, enhancing workability.

It is preferable that the tablet reserving member includes an indicator for indicating that the specially administrative tablets have been fed into the tablet reserving member, thereby preventing mis-operations.

It is also preferable that the tablet reserving member includes a sensor for detecting opening or closing of the lower opening of the tablet reserving member by the shutter, whereby the specially administrative tablets can be fed from the tablet vessel only when the sensor detects closing of the lower opening of the tablet reserving member. Thus, it is possible to prevent mis-operation and feed a desired number of tablets.

BRIEF DESCRIPTION OF THE DRAWINGS

Other objects and features of the present invention will become clear from the following detailed description with reference to the accompanying drawings in which:

FIG. **1** is a perspective overall view illustrating a tablet packing apparatus in accordance with the invention;

FIG. **2**A is a perspective view illustrating a container chamber held in storage shelves in FIG. **1**;

FIG. **2**B is a fragmentary perspective view in FIG. **2**A;

FIG. **3** is a perspective view illustrating an arm member in FIG. **1**;

FIG. **4** is a sectional view illustrating a tablet container section in FIG. **1**;

FIG. **24** is a flow chart illustrating the tablet recovering process in FIG. **23**;

FIGS. **25**A and **25**B are views illustrating a main menu displayed on a touch panel;

FIGS. **26**A and **26**B are front views illustrating contents displayed on the touch panel in the case of power-off;

FIG. **27**A is a perspective view, in part section, illustrating a particular dispensing apparatus for specially administrative tablets;

FIG. **27**B is a sectional view illustrating an example of a tablet container section in FIG. **1** provided the particular dispensing apparatus of FIG. **27**A;

FIG. **27**C is a sectional view illustrating the motor base and the feeder vessel of the particular dispensing apparatus of FIG. **27**A; and

FIG. **28** is a plan view illustrating a tablet feed section provided with a particular dispensing apparatus according to an another embodiment.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

FIG. **1** shows a tablet packing apparatus in accordance with the invention. The apparatus generally comprises storage shelves **1** provided on one end side of the apparatus, a tablet feeding section **2** provided in the upper part of the apparatus, tablet vessel feeding sections **3** provided under the tablet feeding section **2**, a tablet packing section **4** provided between the storage shelves **1** and the tablet vessel feeding sections **3**, and a controlling section **5** (see FIG. **17**).

The storage shelves **1** have a generally semi-cylindrical shape and includes a plurality of container chambers **6**. As shown in FIG. **2**A, each container chamber **6** has a rectangular frame body in which at least the surfaces opposed in the direction shown by an arrow in FIG. **2**A have openings. The openings are closed with doors **6***a* biased by means of unshown springs or so. The doors **6***a* can be opened toward the front surface side, preventing one's hand from being inserted into a packed vessel conveyor **13** that will be explained hereinafter. The doors **6***a* can be pivoted within a range that does not interfere with a tablet vessel **11** held by a vessel holder **8** that will be explained hereinafter. A display **7** is provided on the upper part of the front side of the container chamber **6**. In the embodiment, the feeder vessel number and the tablet count number are displayed on the display **7**. The container chamber **6** is also provided with a vessel holder **8**. In the vessel holder **8**, a pair of holding plates **9** are opposed to each other in a horizontal direction. The holding plates **9** are biased by a spring **9***a* in the direction in which the holding plates **9** come close to each other. At the lower ends of the holding plates **9** are formed holding lugs **10** which extend in the direction in which the holding plates **9** are opposed. As shown in FIG. **2**B, on opposed edges of the holding lugs **10** are formed recesses **10***a* which have a generally elliptic shape so as to hold a tablet vessel **11**. At the back side corners of the holding lugs **10** are formed cutouts **10***b* which are spread out toward the inside. The cutouts **10***b* are provided to facilitate the insertion of the tablet vessel **11** into the recesses **10***a*. A vessel sensor **8***a* is capable of detecting whether the tablet vessel **11** is held by the vessel holder **8** in the container chamber **6** or not.

As shown in FIG. **1**, in the center part of the outer circumference of the storage shelves **1** is provided a touch panel **12**, instead of the container chamber **6**. The touch panel **12** is provided to allow instruction data on the prescription to be inputted directly.

Inside the storage shelves **1** is provided a conveyor **13** for packed vessel. In the conveyor **13** for packed vessel, as shown in FIG. **3**, an arm member **15** is pivotally mounted to a rectangular frame **14** which is capable of traveling vertically.

A bearing recess **16** is provided at each of the upper and lower ends of both outside surfaces of the rectangular frame **14**. The bearing recesses **16** are in sliding contact with guide shafts **17** standing at a given interval behind the storage shelves **1**. The conveyor **13** for packed vessel can be moved vertically through the medium of a belt (not shown) by the driving of a motor (not shown). A first driving gear **18** is fixed to the center of the lower horizontal plate **14***a* of the rectangular frame **14**. Instead of the bearing recess **16**, a roller or a bearing that comes into slide contact with the guide shaft **17** can be used.

The arm member **15** comprises an arm body **19** mounted rotatably on the center shaft of the first driving gear **18**. A first driving motor **20** is provided on one end portion of the arm body **19**. To the rotating shaft of the first driving motor **20** which protrudes from the bottom surface of the arm body **19** are fixed position detection plates **21** and a second driving gear (not shown) engaged with the first driving gear **18**. A rotational position of the second driving gear can be determined by the detection of the position detection plates **21** by a sensor (not shown). With this arrangement, the arm member **15** is rotated in forward or reverse direction in the range of 180° by the drive of the first driving motor **20**. On the top surface of the arm body **19** is provided a sliding member **22** which is driven by a built-in, second driving motor (not shown) and thereby reciprocates in the longitudinal direction. On one end portion of the sliding member **22** (on the side opposite to the first driving motor **20**) is provided a gripping member **23**. The gripping member **23** comprises a pair of gripping pieces **25** which are driven through a gear not shown by a third driving motor **24** provided on the sliding member **22** and thereby open and close.

The third driving motor **24** is driven and stopped based on an electric current value that fluctuates due to a difference of load applied on the gripping pieces **25**. Concretely, when the load of the third driving motor **24** increases at the time of griping and releasing the tablet vessel **11** and then the electric current value exceeds a threshold value (obtained by adding a margin electric current to an electric current value at the normal operation), the third driving motor **24** is stopped. The increase of the load at the time of releasing the tablet vessel **11** is caused by allowing the gripping pieces **25** to come into contact with a stopper (not shown) at a predetermined open position. The gripping pieces **25** are urged toward the open position by an unshown spring or so in order to absorb the backlash of the gear.

The tablet feeding section **2** comprises a tablet container section **26** and a tablet conveyor section **27**.

In the tablet container section **26**, as partly shown in FIG. **4**, grooves **29** extending vertically are provided on both sides of a vertical wall **28**. Each groove **29** is covered with a shelf

member **30** provided pivotably about a pivot **30***a* so that common guide paths **31** are formed. A plurality of openings **30***b* for discharging tablets are provided in a vertical line on each shelf member **30**. A plurality of motor bases **32** corresponding to the openings **30***b* for discharging tablets are mounted to the outer surface of each shelf member **30**.

As shown in FIGS. **5**A and **6**A, each motor base **32** has a built-in driving motor **32***a*. A driving gear **33** to which the power from the driving motor **32***a* is transferred is exposed on the top surface of the motor base **32**. A fall guide path **34** is formed on one end side of the motor base **32**. A tablet detecting sensor **35** is provided on the inner wall of the fall guide path **34**, so that the tablets discharged through the fall guide path **34** can be detected (counted).

A feeder vessel **36** is detachably mounted to the motor base **32**. The feeder vessel **36** is generally in the shape of a rectangle which opens upward and which can be covered with a cover **37**. In the feeder vessel **36** is stored tablets. At the bottom of the feeder vessel **36** is provided a rotor **39** having a gear **38** at the lower end thereof.

As shown in FIGS. **7**A and **7**B, the rotor **39** has conical surfaces on its upper and lower parts. The attachment of the feeder vessel **36** to the motor base **32** engages the gear **38** with the gear **33** on the motor base **32**. On the lower conical surface of the rotor **39** are formed tablet guiding grooves **40** extending spirally toward the center of the surface, and are formed dividing grooves **41** dividing each tablet guiding groove **40** into two parts in the middle thereof. The spiral direction of the tablet guiding grooves **40** toward the center of rotation of the rotor **39** is opposite to the direction of rotation of the rotor **39** (opposite to the direction shown in the arrow in FIG. **7**B). In the dividing grooves **41** is provided a dividing fin **42**. With the rotation of the rotor **39** as shown in FIG. **6**B, the dividing fin **42** divides the line of tablets that pass through the tablet guiding grooves **40**.

As shown in FIG. **5**B, a gear stopper **43** is capable of engaging with the gear **38** in the feeder vessel **36** when the feeder vessel **36** is detached from the motor base **32** and disengaged to the gear **38** when the feeder vessel **36** is mounted. The gear stopper **43** is biased against the gear **38** by a stopper spring **44**. Even though the feeder vessel **36** is detached from the motor base **32**, the above arrangement allows the gear stopper **43** to engage with the gear **38** and prevents the rotor **39** from rotating, so that tablets cannot fall out of the feeder vessel **36**.

In the tablet feeding section **2**, when the driving motor **32***a* in the motor base **32** is driven with the feeder vessel **36** attached to the motor base **32**, the rotor **39** is rotated through the medium of the gear **33** and of the driving gear **38**, thereby tablets move in a line toward the center of rotation, forming a line for each tablet guiding groove **40**. As mentioned above, the tablet guiding grooves **40** are formed so as to extend spirally toward the center of rotation of the rotor **39** in the direction opposite to the direction of rotation of the rotor **39**. Tablets are therefore forced to move toward the center of rotation regardless of the centrifugal forces exerted on the tablets by the rotation of the rotor **39**. The line of tablets is divided by the dividing fin **42** before each tablet guiding grooves **40** communicates with the fall guide path **34**, and then fall one by one into the common guide path **31** through the fall guide path **34**.

As shown in FIG. **4**, at the lower ends of the common guide paths **31** are provided a shutter **43** for temporarily retaining the tablets which have fallen from the fall guide path **34**. The shutter **43** comprises a single plate which can horizontally slide across the common guide paths **31**. At the both end portions of the shutter **43**, openings **43***a*, **43***b* are formed. When the shutter **43** slides toward the left side, the right common guide path **31** is opened by the right opening **43***a*. When the shutter **43** slides toward the right side, the left common guide path **31** is opened by the left opening **43***b*. When the shutter stops at the middle point of the slide stroke, the both of the common guide paths **31** are closd.

Beneath the shutter **43**, a hopper **44** is slidably and detachably disposed. Along with the slide operation of the shutter **43**, the hopper **44** can slide to a position where the hopper **44** can receive the tablets. Thus, the tablets received through the common guide paths **31** can be fed to respective conveyor vessels **46** in the tablet conveyor section **27** disposed beneath the hopper **44**.

The tablet conveyor section **27**, as shown in FIG. **11**, comprises two lines of conveyor belts **48** and conveyor vessels **46**. The conveyor belts **48** are looped between a pair of pulleys **47**. The conveyor vessels **46** are supported on the conveyor belts **48** by a support frame **46***a* so as to be reciprocated. Rectangular apertures **46***c* are provided in a line on a bottom plate **46***b* of the support frame **46***a* (see FIGS. **11** and **15**). The conveyor belt **48** has continual guide projections **48***a*, which engage with the rectangular apertures **46***c* to allow the conveyor vessel **46** to be moved. The bottom of the conveyor vessel **46** comprises a shutter **49** which can be opened and closed. The shutter **49** is biased, as shown in FIG. **15**, by a spring **50** provided at one end of the shutter **49** so as to shut the bottom of the conveyor vessel **46**. A protrusion **49***a* is formed at one end on the downside surface of the shutter **49**.

As shown in FIGS. **8** and **9**, each tablet vessel feeding section **3** comprises a stock container **51** for storing empty tablet vessels **11**, a vessel takeout section **52** for taking out tablet vessels **11** one by one from the stock container **51**, and an empty vessel conveyor **53** for conveying the tablet vessel **11** taken out from the stock container **51** by the vessel takeout section **52**. The tablet vessel feeding sections **3** are disposed in a line as shown in FIG. **1**. The sizes (outside diameters or lengths) of empty tablet vessels **11** stored in the stock containers **51** are different for each stock container **51**.

The bottom wall **54** of the stock container **51** is inclined downwardly toward the vessel takeout section **52** and is provided with a rotation plate **55** in the vicinity of the vessel takeout section **52**. The rotation plate **55** slightly protrudes from the bottom wall **54**. The rotation plate **55** is periodically rotated both forward and backward by a motor **56** so that the inclined direction of the tablet vessels **11** with respect to the vessel takeout section **52** can be changed. On the upper surface of the rotation plate **55**, a semi-spherical shape of protrusion **55***a* is formed. The protrusion **55***a* allows the tablet vessel **11** to change its position lateral and assists in taking out of the tablet vessel **11** by the vessel takeout section **52**. Transmission types of photo sensors **54***a* are provided above the inclined bottom wall **54**. Indication lamps (not shown) provided on the stock container **51** indicate the remaining quantity of the tablet vessels **11** based on the detected signal of the photo sensors **54***a*. Namely, "F" lamp is ON when light between the photo sensors **54***a* is intercepted, while "L" lamp is ON when light between the photo sensors **54***a* is not intercepted. Moreover, "E" lamp is ON when a sensor provided on a conveyor **61** or a delivery table **62** which will be described hereinafter does not detect the tablet vessel **11** for a predetermined time. Alternatively, the remaining quantity of the tablet vessels **11** may be indicated on the touch panel **12** as shown in FIG. **12**

The vessel takeout section **52**, as shown in FIG. **10**, comprises rollers **57** juxtaposed vertically and a belt **58**

running between the rollers **57**. On the belt **58**, lateral vessel holding portions **59** are provided at a predetermined distance along the running direction. Between the lateral vessel holding portions **59**, two vertical vessel eliminating portions **60** are provided. Each lateral vessel holding portion **59** comprises a plurality of holding fingers **59***a* protruding with a predetermined distance. Each vertical vessel eliminating portion **60** comprises a plurality of projections **60***a* protruding with a predetermined distance. The distance between the lateral vessel holding portions **59** is smaller than the height of the tablet vessel **11** and larger than the outside diameter of the tablet vessel **11**. The distance between the holding fingers **59***a* is larger than the outside diameter of the tablet vessel **11**. Thus, the lateral vessel holding portions **59** can surely hold the tablet vessel **11** laterally without engaging the open edge of the tablet vessel **11** with the holding fingers **59***a*.

The vessel takeout section **52** further comprises a conveyor **61** and a delivery table **62** for conveying the tablet vessels **11** taken out by the vessel takeout section **52** to the empty vessel conveyor **53**. The conveyor **61** comprises a pair of rollers **68** and four conveyor ropes **69** running between the rollers **68**. The roller **68** is driven to rotate both forward and backward by a motor not shown. The distance between the conveyor ropes **69** is smaller than the outside diameter of the tablet vessel **11**. The delivery table **62** has a substantially L shaped section and is pivotable between positions as shown in solid line and two dots chain line respectively in FIG. **9** to deliver the tablet vessels **11** conveyed by the conveyor **61** to the empty vessel conveyor **53**. The vessel takeout section **52** is operated when no tablet vessel **11** is detected on the conveyor **61** or delivery table **62** by a sensor not shown for a predetermined time. The empty vessel conveyor **53** is operated in a reverse conveying direction for a predetermined time at the time of power ON initially and after emergency stop. If the empty tablet vessel **11** is present on the way of the empty vessel conveyor **53**, the empty tablet vessel **11** is recovered into a recovery box not shown disposed on one end of the empty vessel conveyor **53**, namely on the end opposite to the tablet packing section **4**.

The empty vessel conveyor **53** is provided below the delivery table **62** along the stock containers **51** arranged in line. In the same manner as the conveyor **66**, the empty vessel conveyor **53** comprises a pair of pulleys **71** and a pair of conveyor ropes **72** looped between the pair of pulleys **71**.

As shown in FIG. **11**, the tablet packing section **4** comprises a fork-like vessel holder section **76** and a tablet weighing section **77**.

The vessel holder section **76** has a plurality of support pieces **78** between which the tablet vessel **11** can be supported. The distance between the support pieces **78** corresponds to the size of the tablet vessels **11**. In the present embodiment, the vessel holder section **76** can hold S, M and L sizes of the tablet vessels **11**. The vessel holder section **76** can reciprocate between a vessel receiving position and a tablet receiving position by means of drive unit not shown.

In the vicinity of the vessel receiving position, first, second and third guide plates **79**, **80** and **81** are disposed. The first guide plate **79** has a substantially V-shape so that the tablet vessel **11** conveyed by the empty vessel conveyor **53** can be delivered to the second guide plate **80**. The second guide plate **80** is inclined so that the tablet vessel can roll on the second guide plate **80** toward the vessel holder section **76**. The third guide plate **81** can pivot above the second guide plate **80** for allowing or disallowing the tablet vessel **11** to be passed to the vessel holder section **76**. The third guide plate **81** may be provided with a delivery guide plate which allows the tablet vessel **11** to surely roll.

Under the vessel holder section **76**, a vessel aligning plate **82** is disposed. The vessel aligning plate **82** allows the tablet vessels **11** held by the support pieces **78** to align when the vessel holder section **76** is horizontally moved. Thus, it is possible to reduce push quantity by push rollers **92** which will be described hereinafter, resulting in effective operation.

In the vicinity of the tablet receiving position, there are provided a labeler **83** and a lifter **84**.

The labeler **83** is arranged to print a medicine name or so on labels **85** and fix the labels **85** to the tablet vessels **11**. The labels **85** are in advance stuck to a sheet **87** wound on one roller **86***a* and released from the sheet **87** when the sheet **87** is turned at a guide tip **88**. The sheet **87** with the labels **85** released is rewound on the other roller **86***b*. Printing to the labels **85** is carried out before releasing the labels **85** from the sheet **87** in such a manner that printing information is heat transferred through a ribbon **90** by means of printing head **89** as the sheet **87** is supported with a backing roller **86***c*. The ribbon **90** is fed from one roller **91***a* and rewound on the other roller **91***b*.

Under the vessel holder section **76**, a pair of push rollers **92** and a guide roller **93** are disposed. A size detecting sensor (not shown) for detecting the size of the tablet vessels **11** is provided between the push rollers **92**. The push rollers **92** are arranged to push the tablet vessel **11** aligned by the vessel aligning plate **82** in a protruding direction of the support pieces **78**, whereby holding the tablet vessel **11** together with the guide roller **93** positioned on the other side. Beneath the tablet vessel **11** held by the push rollers **92** and the guide roller **93**, a rotation bearing table **110** is disposed. The rotation bearing table **110** can be raised up to a height corresponding to the size of the tablet vessel **11** detected by the size detecting sensor. The guide roller **93** is urged toward the push roller **92** and rotates the tablet vessel **11** due to drive of a motor **93***a*.

The lifter **84** can lift up the tablet vessel **11** up to a rotation position where a flange portion of the tablet vessel **11** is positioned slightly above the support pieces **78** and a tablet receiving position where the tablet vessel **11** receive the tablets from a packing hopper **97** which will be described hereinafter.

The tablet weighing section **77** comprises an input hopper **94**, a weighing section **95**, a measuring hopper **96**, a packing hopper **97**, and a discharging hopper **98**.

As shown in. FIG. **15**, the approach of the conveyor vessel **46** to the input hopper **94** brings the protrusion **49***a* of the shutter **49** into contact with an edge of the input hopper **94**, causing the shutter **49** to open against the bias exerted by the spring **50**. This operation allows the tablets accommodated in the conveyor vessel **46** to fall into the input hopper **94**.

As shown in FIGS. **11** and **15**, the weighing section **95** comprises a weighing vessel **99** for accommodating tablets which have fallen from the input hopper **94**, a weighing device **100** for weighing the weighing vessel **99** along with the accommodated tablets, and a pair of arms **101** for supporting the weighing vessel **99**. Two projections **99***a*, **99***b*, as shown in FIG. **16**A, are formed on each outside surface on both sides of the weighing vessel **99**. At the distal end of each arm **101** is formed an engaging recess **101***a* which engages with the projection **99***a* at one end. The engaging recess **101***a* is so shaped that the projections **99***a* on the weighing vessel **99** are prevented from falling out when tablets in the weighing vessel **99** are fed into the

packing hopper **97** with the pivotal motion of the arms **101**. When tablets are fed from the input hopper **94** into the weighing vessel **99**, the arms **101** suspend the weighing vessel **99** above the weighing device **100** so that the impulsive force caused by the feeding cannot act directly on the weighing device **100**. After the feeding, the arms **101** pivot to load the weighing vessel **99** on the weighing device **100**. With this arrangement, the measuring time by the weighing device **100** is shortened.

The bottom surface of the measuring hopper **96** comprises a shutter **96***a* as shown in FIG. **11**. Packing amount detecting sensors **102** are provided on the side surfaces facing each other of the measuring hopper **96**, so that the amount of the tablets stocked in the measuring hopper **96** can be determined.

The upper openings of the packing hopper **97** and of the discharging hopper **98** are closed and opened by a closing/opening door **103** provided pivotably. The lower end of the packing hopper **97**, as shown in FIG. **14**, extends so as to gradually reducing its diameter and connects to a lower cylindrical portion **110** to form a step like shape. In the lower cylindrical portion **110**, an internal cylinder **111** is disposed so as to move vertically. A hood **112** is fixed on the upper end of the internal cylinder **111** so that the food **112** can open and close the internal opening **110***a* of the lower cylindrical portion **110**. Thus, when the tablet vessel **11** is raised by the lifter **84** to push up the internal cylinder **111**, tablets sustained by the hood **112** are discharged into the tablet vessel **11**.

As shown in FIG. **17**, the controlling section **5** receives an input of prescription data from a host computer **105** (or only an input signal from the touch panel **12**). The controlling section **5** also receives a signal from or actuates and controls the storage shelves **1** (e.g., the vessel sensors **8***a*, the touch panel **12**, motors **14***a*, the first driving motor **20**, and the third driving motor **24**), the tablet feeding section **2** (e.g., the driving motors **32***a*, and the tablet detecting sensors **35**), the tablet vessel feeding sections **3**, and the tablet packing section **4** (e.g., the weighing device **100**, the packing amount detecting sensors **102**) and an emergency stop switch **106** and so on.

The operation of the tablet packing apparatus as arranged above will be described below.

As shown in the flow chart of FIG. **18**, first, prescription specifying data based on prescription data is received from the host computer **105** (step S1). A empty tablet vessel feeding process (step S2) and a tablet feeding process (step S3) are then performed simultaneously in parallel on the basis of the prescription specifying data. Subsequently, a tablet packing process (step S4) is performed, and a vessel delivering process (step S5) is then performed for delivering the tablet vessel **11** to the container chamber **6** in the storage shelves **1**. The prescription specifying data may be received in multiple according to the processing capacity.

In the empty vessel feeding process, as shown in the flow charts of FIG. **19**, in accordance with the above prescription data, the vessel takeout section **52** in the stock container **51** in which the tablet vessels **11** corresponding to the prescription data are contained is operated (step S11). In the vessel takeout section **52**, the tablet vessels **11** are conveyed upward in laterally held condition by the lateral vessel holding portions **59**. At this time, the vertical vessel eliminating portions **60** prevent the tablet vessels **11** from being held by the lateral vessel holding portions **59** in a vertical condition or in a laterally overlaid condition. Feeding of the next tablet vessel **11** is carried out by operating the vessel takeout section **52** in the stock container **51** when use of the tablet vessel **11** held on the vessel holder section **76** is decided, i.e., when the next prescription data is inputted.

When the tablet vessel **11** is conveyed upward by the vessel takeout section **52**, operation of the conveyor **61** is commenced to move the tablet vessel **11** to the delivery table **62** (step S12). Then, activation of the solenoid not shown causes the delivery table **62** to pivot, whereby the tablet vessel **11** is delivered to the empty vessel conveyor **53** (step S13).

In the empty vessel conveyor **53**, after the tablet vessel **11** is delivered from the stock container **51**, the motor not shown is driven to convey the tablet vessel **11** to the tablet packing section **4** by the conveyor ropes **72** (step S14).

In the tablet packing section **4**, the tablet vessel **11** is delivered to the second guide plate **80** through the first guide plate **79** and then guided by the third guide plate **81** (step S15) . The vessel holder section **76** is horizontally moved to position the pair of the support pieces **78** corresponding to the size of the tablet vessel **11** to be conveyed at the lower end edge portion of the second guide plate **80** (step S16). Then, the third guide plate **82** is pivoted so that the tablet vessel **11** is supported by the support pieces **78** of the vessel holder section **76** (step S17). As a result, the flange portion of the tablet vessel **11** is supported, whereby the tablet vessel **11** necessarily becomes to be an upwardly opened condition.

The support positions of the tablet vessels **11** on the support pieces **78** are different in accordance with the sizes and the delivery directions of the tablet vessels **11**. Therefore, the vessel holder section **76** is horizontally moved, whereby the tablet vessels **11** are aligned by the vessel aligning plate **82** (step S18). If the tablet vessel **11** reaches the tablet receiving position (step S19), then the movement of the vessel holder section **76** is stopped (step S20). Consequently, the lifter **84** is driven to slightly lift the tablet vessel **11** from the vessel holder section **76** (step S21). In this condition, the push rollers **92** are moved forward (step S22), thereby the tablet vessel **11** is held by the push rollers **92** and the guide roller **93**. Then, the motor **93***a* is driven to rotate the guide roller **93** so that the label **85** on which a predetermined information is printed is fixed on the outer surface of the tablet vessel **11** (step S23).

In the tablet feeding process, as shown in the flow chart of FIGS. **20** and **21**, a relevant tablet container section **26** is actuated and controlled on the basis of the prescription specifying data. That is, the built-in motor in the relevant motor base **32** is driven to rotate the rotor **39** to discharge a given number of the tablets stored in the feeder vessel **36** (step S41). The number of the discharged tablets is counted by the tablet detecting sensor **35** provided in the fall guide path **34** (step S42). After the given number of tablets are discharged from the feeder vessel **36** through the fall guide path **34** into a common guide path **31** (step S43), the rotation of the rotor **39** is halted to suspend the discharge of tablets (step S44).

The tablet conveyor section **27** is then actuated and controlled; that is, the pulleys **47** are driven and rotated so that the conveyor vessel **46** is moved by the conveyor belt **48** and positioned under the common guide path **31** (step S45). The hopper **44** is then rotated to direct the opening thereof to the conveyor vessel **46** (step S46), and the shutter **49** is opened to allow the tablets to be stored into the conveyor vessel **46** (step S47).

After the given number of the relevant tablets are stored in the conveyor vessel **46**, the conveyor vessel **46** is moved to the input hopper **94** by the actuation and control of the

tablet conveyor section **27** (step S**48**). At this time, the protrusion **49***a* of the shutter **49** comes into contact with an edge of the input hopper **94**, and the movement of the conveyor vessel **46** thereby causes the shutter **49** to open gradually, so that the stored tablets are inputted into the weighing vessel **99** through the input hopper **94**. The weighing vessel **99** is then suspended slightly above the weighing device **100** by the pivotal motion of the arms **101**, so that the impulsive force caused by the input of the tablets cannot act directly on the weighing device **100**. Subsequently, the weighing vessel **99** is loaded on the weighing device **100** by the pivotal motion of the arms **101** and the weight of the weighing vessel **99** is measured (step S**49**).

It is then judged whether the weight is as large as a given weight or not (step S**50**). The tablets are then fed into the measuring hopper **96** by the pivotal motion of the arms **101** (step S**51**). Whether the amount of the tablets is within the capacity of the tablet vessel **11** or not is then judged on the basis of detection signals from the packing amount detecting sensors **102** in the measuring hopper **96** (step S**52**).

In the case that the weight is as large as the given value and that the amount of the fed tablets is not more than the given amount, it is judged that the relevant tablets could be packed by the given amount. Then, the tablet vessel **11** is further lifted by the lifter **84** so that the internal cylinder **111** of the packing hopper **97** is raised (step S**53**). As a result, the internal opening **110***a* is opened by the hood **112**, whereby the tablets are packed in the tablet vessel.

In the case that the weight is larger or smaller than the given value or that the amount of the fed tablets is larger than the given amount, it is judged that the tablets are irrelevant or that the amount of the tablets exceeds the capacity of the tablet vessel **11**. The opening of the packing hopper **97** is then closed (step S**54**), and the shutter **96***a* is opened (step S**55**). The tablets are thus discharged through the discharging hopper **98**. In this case, returning to step S**41**, the tablet feeding process is performed afresh.

After the tablets are packed into the tablet vessel **11**, the process for delivering the vessel to the storage shelves **1** is performed. At this time, a using condition of the container chamber **6** is confirmed by referring to a storage shelves data table and a vacant container chambers **6** are specified. The storage shelves data table is established based on detected signal of the vessel sensor **8***a* provided in each container chamber **6** of the storage shelves **1**. Among the vacant container chambers **6**, the order of the container chambers **6** in which the tablet vessel **11** is to be delivered is decided. In the present embodiment, the order of positions of the container chambers **6** that an operator can easily take out the tablet vessel **11** is decided.

After the container chamber **6** to which the tablet vessel **11** is to be delivered is decided, as shown in FIG. **22**, the arm member **15** is caused to pivot (step S**61**), the sliding member **22** is moved forward relative to the arm body **19** (step S**62**), and the tablet vessel **11** is gripped by the gripping pieces **25** (step S**63**). The sliding member **22** is then retracted (step S**64**), and the arm member **15** is caused to pivot and elevated (step S**65**). The position where the arm member **15** is to reach with the pivotal motion and elevation is such a position as determined as described above, i.e., the container chamber **6** from which the operator can easily take out the tablet vessel **11**.

Once the arm member **15** reaches the determined position to reach with the pivotal motion and elevation (step S**66**), a using condition of the container chamber **6** is confirmed again based on the detected signal of the vessel sensor **8***a* provided in the corresponding container chamber **6**. If the tablet vessel **11** is not contained, the sliding member **22** is moved forward to open the door **6***a* and deliver the gripped tablet vessel **11** to the container chamber **6** in the storage shelves **1** (step S**67**). The tablet vessel **11** then travels to the recesses **10***a* while pushing aside the holding plates **9** in the container chamber **6** through the medium of the cutouts **10***b* formed in the holding lugs **10**, and is held with the bias exerted by the spring **9***a*. The gripping pieces **25** are then released (step S**68**); the sliding member **22** is retracted (step S**69**); and the arm member **15** is subsequently lowered (step S**70**) for the delivery of the next tablet vessel **11**. Just before the tablet vessel **11** is contained in the container chamber **6**, if a tablet vessel **11** is detected in the container chamber **6**, another container chamber **6** in which the tablet vessel **11** can be contained is retrieved and then the tablet vessel **11** is contained in the retrieved container chamber **6**.

In the selection of the aimed container chamber **6**, the container chambers **6** may be numbered so that the number increases with increase in the period of time required for the delivery of a tablet vessel **11** to the container chamber **6** by the arm member **15**, and the vacant container chamber **6** which has the smallest number may be selected as the aimed chamber.

Once the tablet vessel **11** packed with the given amount of the specified tablets is thus delivered to the container chamber **6** in the storage shelves **1**, the numbers assigned to the feeder vessels and the counts of the tablets are displayed on the display **7** of the relevant container chamber **6** in response to a detection signal from the vessel sensor **8***a* (step S**71**).

In the aforementioned tablet packing apparatus, when an emergency stop button which is provided in both the lower middle portion of the storage shelves **1** and the middle potion of the tablet vessel feeding sections **3** is pressed down, or power supply is cut off due to power failure or the like during the operation, the apparatus is shut down. In this case, the power supply to the motor base **32** which operates the tablet container section **26** is stopped, preventing miss-feeding of the tablets. Whereas, the power supply to the controlling section **5** is not stopped and it is communicated to the controlling section **3** that it is an emergency stop condition. At the normal stop of the power supply, without simultaneously stopping the power supply to both the motor base **32** and the controlling section **5**, the power supply to the motor base **32** is stopped first and then the power supply to the controlling section **5** is stopped. The controlling section **5** is possible to receive power supply from a secondary power source not shown, the operating condition is maintained. However, there may arise a case that an information on the tablet vessel **11** and the tablet which had been under conveyance can not be perfectly controlled. Thus, it is required to execute a restoring process in which the tablet vessel **11** and the tablet which had been under conveyance is recovered to reset the information.

In the restoring process which will be explained in detail hereinafter, the tablet vessel **11** and the tablet which had been under conveyance is recovered into the container chambers **6** of the storage shelves **1**. Therefore, in the case that there is no room or few room for the container chambers **6**, the tablet vessels **11** should be removed from the container chambers **6** so that the restoring process can be executed. Moreover, in the conveyance path of the tablet vessels **11** (the empty vessel conveyor **53**, the vessel holder section **76** and so on), the empty vessel conveyor **53** is reversed for a predetermined time to remove the tablet vessel **11** on the empty vessel conveyor **53**. In the vessel holder section **76**, the size data of the tablet vessel **11** is memorized again by

means of the size detecting sensor for detecting the size of the tablet vessel **11** provided between the push rollers **92**.

It is preferable to make an indication on the touch panel **12** that the tablet is removed. Since an error that either the feeder vessels **36** or the stock vessel **51** is empty does not shows abnormality, the restoring process is not executed in such case.

The restoring process will be explained in accordance with the flow chart as shown in FIG. **23**.

The controlling section **5** is once powered off (step S**81**). This is because of the deletion of the processing data temporally stored in the memory of the controlling section **5**. When an area displayed on the touch panel **12** by "CLOSE" as shown in FIG. **25**A is touched, the indications of "DO YOU WANT TO POWER OFF?", "YES" and "NO" are displayed as shown in FIG. **26**A. If the "YES" is selected, the indication that "IT'S SAFETY EVEN IF POWER IS POWERED OFF" is displayed as shown in FIG. **26**B to power off.

If the emergency stop button is pressed down (step S**82**), then the emergency stop button is reset (step S**83**) and the controlling section **5** is powered on again (step S**84**). Thus, the menu is displayed on the touch panel **12** as shown in FIG. **25**A.

Among the items as shown in FIG. **25**A, if the "RECALL" is touched (step S**85**), then the recovering process of the tablet which had been under conveyance is commenced (step S**86**). At this time, the indication that "RECALL UNDER PROCESS . . . " is displayed on the touch panel **12** as shown in FIG. **25**B to indicate that restoring process is going on (step S**87**).

In the tablet recovering process, the tablets remaining in the conveyor vessels **46** and the hoppers **44** are recovered as shown in flow chart of FIG. **24**. At first, the vessel holder section **76** is moved to position the tablet vessel **11** having the largest capacity at the packing position, i.e., beneath the packing hopper **97** (step S**91**). Normally, since the tablet vessel **11** having the largest capacity is ready on the vessel holder section **76**, such tablet vessel **11** is used. If such tablet vessel is not ready, it is replenished from the stock vessel **51**. On the other hand, the tablets are recovered from any one of the common guide paths by means of the conveyor vessel **46** (step S**92**). Then, the tablets are packed into the largest tablet vessel **11** through the input hopper **94** and the packing hopper and so on (step S**93**). Consequently, the tablet vessel **11** packed with the tablets is transferred to the container chamber **6** of the storage shelves **1** by the arm member **15**. At the same time, a tablet vessel **11** having the same size as the tablet vessel transferred to the storage shelves **1** is replenished to the vessel holder section **76** (step S**95**). In addition, the indication of "P000" is displayed on the display **7** (step S**96**) to enable an operator to distinguish at a glance that the recovered tablets are packed in the tablet vessel **11** transferred to the container chamber **6**.

In the same manner as explained above, a tablet vessel **11** having the largest capacity is replenished to the vessel holder section **76** from the stock vessel **51** to recover the tablets remaining in the another common guide paths **31**. Although there may be no tablet in the common guide paths **31**, the recovery process of tablets should be executed from all of the common guide paths **31** in order to perfectly grasp which tablets had been under conveyance.

If the tablets remaining in all common paths **31** (step S**97**) is recovered, then other size of the tablet vessels **11** held on the vessel holder section **76** are recovered to the storage shelves **1** (step S**98**). In this case, the tablet vessels **11** having the same size as that of the tablet vessels **11** which are recovered and transferred to the container chamber **6** of the storage shelves **1** are replenished to the vessel holder section **76** from the corresponding stock vessel **51** (step S**99**).

If the recovery of the tablet vessels is finished (step S**100**), then main menu is displayed on the touch panel **12**. The touch with "AUTO" enables the restoration to the normal operation, i.e., the tablet vessel feeding process (step S**2**), the tablet feeding process (step S**3**) and the tablet packing process (step S**4**) in the same manner as described before.

In the above explained restoring process, in the case that the tablet packing apparatus is stopped due to the abnormality, the controlling section **5** is always powered off to clear the processing data stored in the memory. However, it may be also possible to have the operator select whether such processing data is utilized or not. For example, when the indication of "RECALL" displayed on the touch panel **12**, the processing data which are stored before the apparatus is stopped may be utilized to continue the process. In this case, the tablet vessels **11** remaining in the empty vessel conveyor **53**, the vessel holder section **76** and so on, or the tablets remaining in the common guide paths **31** and the like are not necessary to be recovered.

Moreover, in the above explained restoring process, the indication of "P000" indicating recovery is displayed on the display **7** of the container chamber **6**. Instead of this, it is also possible to indicate which feeder vessel **36** the tablets were discharged from. In this case, it is necessary to memorize the common guide path from which the tablets were recovered based on the position of the conveyor vessel **46**. Thus, according to both the memorized common guide path and the processing data, it is possible to specify the feeder vessel **36** from which the tablets were discharged.

Oftentimes the tablets to be contained in the tablet feeding section **2** include specially administrative tablets (for example, pyrine medicines and histamine tablets which cause allergy). Therefore, if a packing operation is carried out through a common passage, there would be a risk that the drug forming the specially administrative tablets would intermingle or mix with the other tablets due to the troubles and so on of the apparatus. Therefore, it is preferable to provide a particular dispensing apparatus, in the tablet feeding section **2**, containing the specially administrative tablets.

As shown in FIG. **27**A and FIG. **27**C, the particular dispensing apparatus comprises a tablet reserving member **200** for temporarily reserving the tablets fed from the motor base **32**'. An upper opening **208** of the tablet reserving member **200** communicates with a fall guide path **207** in the motor base **32**'. An LED **201** is provided on the front surface of the motor base **32**'. The LED **201** is ON when the tablets are received in the tablet reserving member **200** from the motor base **32**'. The lower opening of the tablet reserving member **200** can be closed by a shutter **203** which is rotatably supported around a support shaft **203***a* on a support member **202**. The shutter **203** is formed with an arc-like cutout **204** on its front edge and also provided with a detection piece **205** on its side edge. The cutout **204** is arranged so as to engage the flange of the tablet vessel with the internal edge of the cutout **204** in order to position the tablet vessel **11** to push the shutter **203**. The detection piece **205** is detected by a sensor **206** provided on the support member **202** when the lower opening of the tablet reserving member **200** is closed by the shutter **203**. The shutter **203** is urged by urging means such as a spring or the like (not shown) so that the lower opening of the tablet reserving member **200** can be closed.

In the tablet feeding section **2** with the particular dispensing apparatus having the above-described construction, when the motor base **32**' is driven and the specially administrative tablets are received in the tablet reserving member **200**, the LED **201** is ON. Thus, an operator can recognize at a glance from which tablet feeding section **2** the specially administrative tablets were discharged. Then, the operator sets the tablet vessel **11** on the particular dispensing apparatus of the tablet feeding section **2** in which the LED **201** is ON. Consequently, with the tablet vessel **11** engaged with the cutout **204**, the operator pushes the shutter **203**. As a result, the shutter **203** is pivoted around the support shaft **203***a* against the force of the urging means. Thus, the upper opening of the tablet vessel **11** can communicate with the lower opening of the tablet reserving member **200**, and thereby the specially administrative tablets in the tablet reserving member **200** are packed or received in the tablet vessel **11**. At this time, as the sensor **206** does not detect the detection piece **205** of the shutter **203**, the LED **201** is OFF.

Instead of the tablet reserving member **200** shown in FIGS. **27**A–**27**C, a tablet reserving member having such a construction as shown in FIG. **28** with a shutter **300** and sensors **301***a*, **301***b* can be adopted.

The shutter **300** has a fan-shape. On the front edge thereof the shutter **300** is formed with a guide portion **302** comprising an arc-like cutout, while on the rear edge thereof the shutter **300** is formed with a protrusion **303** which is detected by sensors **301***a*, **301***b*. The shutter **300** is urged in a counterclockwise direction in FIG. **28** around a support shaft **301***a* by a spring **304** provided around the support shaft **301***a*. Therefore, if no load is applied, the shutter **300** closes the lower opening **305** of the tablet reserving member. The guide portion **302** is directed toward the front side, allowing the upper opening of the tablet vessel **11** to position easily in place. The protrusion **303** is detected by the sensor **301***a*, i.e., the closes condition of the shutter **300** is detected by the sensor **301***a*, whereby the tablets can be fed from the motor base **32**. However, after the tablets are discharged in the tablet reserving member, the tablets can not be fed from the motor base **32** unless the opened condition of the shutter **300** is detected. Thus, the feed of the tablets are controlled based on the signals from the sensors **301***a*, **301***b* and the motor base **32**, whereby the feed of the tablets can be constantly properly conducted.

In the aforementioned embodiment, to the tablet feeding section **2** with the specially administrative tablets contained, the tablet reserving member **200** of the particular dispensing apparatus is directly fixed. However, the tablet reserving member **200** may be connected to the tablet feeding section **2** via a tube or so. Thus, it is possible that the tablet reserving member **200** have a mounting and dismounting construction and is disposed at a proper position to dispense the specially administrative tablets.

Although the present invention has been fully described by way of the examples with reference to the accompanying drawing, it is to be noted that here that various changes and modifications will be apparent to those skilled in the art. Therefore, unless such changes and modifications otherwise depart from the spirit and scope of the present invention, they should be construed as being included therein.

What is claimed is:

1. A tablet packing apparatus in which tablets fed from a plurality of feeder vessels in a tablet feed section through a common guide path are packaged in a tablet vessel fed from a tablet vessel feed section, the apparatus comprising:

a fall guide path formed in a motor base on which a feeder vessel, which stores specially administrative tablets, is mounted, wherein the fall guide path does not communicate with the common guide path;

a tablet reserving member disposed below the motor base on which the feeder vessel which stores specially administrative tablets is mounted, the tablet reserving member having an upper opening which communicates with the fall guide path of the motor base and a lower opening, the tablet reserving member receiving the specially administrative tablets fed from the feeder vessel through the fall guide path of the motor base; and

a shutter which is movable to open and close the lower opening of the tablet reserving member, wherein when setting the tablet vessel beneath the tablet reserving member and moving the shutter to open the lower opening of the tablet reserving member, the specially administrative tablets are fed into the tablet vessel without passing through the common guide path.

2. The tablet packing apparatus as in claim **1**, wherein the tablet reserving member is separated from the feeder vessel and connected to the feeder vessel by means of a tube.

3. The tablet packing apparatus as in claim **1**, wherein the tablet reserving member includes a biasing member for biasing the shutter so as to close the lower opening of the tablet reserving member and the shutter is formed with a cutout portion with which the tablet vessel engages, whereby when engaging the tablet vessel with the cutout portion to push the shutter, the shutter open the lower opening of the tablet reserving member.

4. The tablet packing apparatus as in claim **1**, wherein the tablet reserving member includes a indicator for indicating that the specially administrative tablets are fed into the tablet reserving member.

5. The tablet packing apparatus as in claim **1**, wherein the tablet reserving member includes a sensor for detecting opening or closing of the lower opening of the tablet reserving member by the shutter, whereby the specially administrative tablets can be fed from the tablet vessel only when the sensor detects closing of the lower opening of the tablet reserving member.

6. A tablet packing apparatus including a tablet feed section comprising a plurality of tablet feeder vessels for feeding tablets through a common guide path to a tablet vessel, said tablet feed section further comprising:

at least one motor base defining a tablet fall guide path that does not communicate with the common guide path;

a feeder vessel, mounted on said motor base, for storing specially administrative tablets;

a tablet reserving member disposed below said motor base, said tablet reserving member having a lower opening and an upper opening communicating with the fall guide path of said motor base such that said tablet reserving member receives the special administrative tablets fed from said feeder vessel; and

a shutter for opening and closing the lower opening of said tablet reserving member, wherein said shutter can be moved from a closed position to an open position by moving a tablet vessel beneath said tablet reserving member and engaging said shutter to open the lower opening and feed the specially administrative tablets into the tablet vessel without passing through the common guide path.

7. The tablet packing apparatus as claimed in claim **6**, wherein said tablet reserving member is connected to said feeder vessel by means of a tube.

8. The tablet packing apparatus as claimed in claim **6**, wherein said tablet reserving member includes a biasing member for biasing said shutter into a position closing the

lower opening of said tablet reserving member, and said shutter is formed with a cutout portion for engaging a tablet vessel such that when the cutout portion is engaged with the tablet vessel, said shutter is moved so as to open the lower opening of said tablet reserving member.

9. The tablet packing apparatus as claimed in claim **6**, wherein said tablet reserving member includes an indicator for indicating that the specially administrative tablets have been fed into said tablet reserving member.

10. The tablet packing apparatus as claimed in claim **6**, wherein said tablet reserving member includes a sensor for detecting whether the lower opening of said tablet reserving member is open or closed by said shutter so that the specially administrative tablets can be fed from said feeder vessel only when said sensor detects that the lower opening of said tablet reserving member is closed.
