OPTICAL RECORDING MEDIA**TECHNICAL FIELD**

The present invention relates to an optical recording medium and in particular, to an optical recording medium of a writable type using an organic pigment as a recording material.

BACKGROUND OF THE INVENTION

With the advent of information-oriented society, a request for a large-capacity memory for recording a great amount of information such as image, voice, and data is becoming stronger and stronger.

In order to answer such a request, a disc-shaped optical recording medium has a large recording capacity and a high reliability as recording and reproduction are carried out in a non-contact state. Besides, such a disc-shaped optical disc has various other merits that it can easily be carried and produced at reasonable costs in a mass production, and has been widely spread up to now.

As a recording material of an optical recording medium, there have been proposed various materials: rare earth-transition metal amorphous alloy thin film such as Tb—Fe—Co, a phase change material such as Ge—Se—Te, an organic pigment material such as cyanine pigment. Among these materials, the organic pigment is used in a writable optical recording medium on which a user can write in once. This material has no problem of corrosion and is low in toxicity, which is a merit that only a small environmental load is caused.

As a specific configuration example of an optical recording medium using such an organic pigment, there can be exemplified the following.

Firstly, there can be exemplified an air sandwich configuration consisting of two light transmitting substrates each having a recording layer containing an organic pigment and bonded so as to oppose the recording layers to each other and to form an air layer between the substrates. This air sandwich type optical recording medium is available in market for data recording.

After this, the Proceeding of SPIE, vol. 1078, page 1078 discloses a configuration having a recording layer containing an organic pigment, an optical reflection layer, and a protection layer successively formed on a light transmitting substrate, i.e., a normal compact disc configuration having a recording layer containing an organic pigment. As this optical recording medium has a high reflection ratio of 70% or above in a wavelength band of 780 nm used in a compact disc, after recording it is possible to obtain a signal characteristic compatible with a compact disc on market. This optical recording medium is used for music recording, video recording, and a personal computer data recording and now is forming a large market.

Moreover, in the field of optical recording, besides such a recording material and medium configuration, study has been made on the optical system for recording.

That is, in the optical recording medium, a laser beam is used for recording and reproduction.

In recording, a laser beam is focused on a recording layer and within the laser spot, an optical change is generated in the recording layer so as to form a pit. Moreover, in reproduction, a laser beam is focused on the pit so as to detect a difference between the reflection ratios of the pit and a portion not having the pit. The recording density on such

an optical recording medium is determined by a laser beam spot diameter. As this spot diameter is reduced, it is possible to record with a higher density.

On the other hand, the laser beam spot diameter is proportional to the L/NA of the optical recording/reproduction optical system (wherein NA is a numerical aperture of the objective lens and L is the wavelength of the laser beam). Consequently, the recording density of the optical recording medium is determined by the numerical aperture NA of the objective lens used in this optical system and the wavelength L of the laser source. As the NA increases and the L decreases, the recording density can be increased.

For this, recently, a study has been made so as to reduce the wavelength of the semiconductor laser as a laser source. For example, as reported in "O plus E", vol 199, page 71 (1996), there is a trial to apply a semiconductor laser having a wavelength band of 630 nm to 650 nm for optical recording.

However, when reducing the wavelength of the laser beam for recording and reproduction, it is necessary to select a recording material matched with the wavelength band. An organic pigment is selected because of having a sufficient optical absorption and reflection ratio in the wavelength band of the laser beam for recording and reproduction.

For this purpose, for example, organic pigments to be used for 630 nm to 650 nm are disclosed in Japanese Patent Laid-Open 6-40161, Japanese Patent Laid-Open 6-40162, Japanese Patent Laid-Open 6-199045, and Japanese Patent Laid-Open 7-186530.

However, these organic pigments do not have a sufficient optical absorption or reflection ratio in the range from 630 nm to 650 nm and have a problem in the recording sensitivity and the signal modulation degree.

SUMMARY OF THE INVENTION

It is therefore object of the present invention to provide an optical recording medium showing a high reflection ratio and an appropriate optical absorption in the short wavelength range of 630 nm to 650 nm and enabling a preferable recording and reproduction characteristic.

In order to achieve the aforementioned object, the inventor studied and found that a polymethine pigment having 1 to 4 carbons in the methine main chain and an atomic groups including a predetermined aromatic ring at both ends enables a high reflection ratio and an appropriate optical absorption in a wavelength band from 630 nm to 650 nm.

The optical recording medium according to the present invention has been proposed according to the aforementioned finding and includes a recording layer and reflection layer formed on a light transmitting substrate, the recording layer formed as (1) a pigment layer containing at least one of a pigment compound a, pigment compound b, and pigment compound c; (2) an organic pigment layer containing at least two of the pigment compound a, the pigment compound b, and the pigment compound c; (3) an organic pigment layer containing at least one of the pigment compound a, the pigment compound b, and the pigment compound c in combination with at least one of a pigment compound d, a pigment compound e, and a pigment compound f; (4) an organic pigment layer containing at least one of the pigment compound a, the pigment compound b, and the pigment compound c in combination with a pigment compound g, a pigment compound h, a pigment compound i, and a pigment compound j; (5) an organic pigment layer containing at least one of the pigment compound a, the

3

pigment compound b, and the pigment compound c in combination with at least one of the pigment compound d, the pigment compound e, and the pigment compound f in combination with at least one of the pigment compound d, the pigment compound e, and the pigment compound f; (6) an organic pigment layer containing at least two of the pigment compound d, the pigment compound e, and the pigment compound f; or (7) an organic pigment layer containing at least one of the pigment compound d, the pigment compound e, and the pigment compound f, and pigment compound j in combination with at least one of the pigment compound d, the pigment compound e, and the pigment compound f.

These organic pigment layers enable a high absorption degree and a reflection ratio in the wavelength band from 630 nm to 650 nm and show a small wavelength dependency in this range. Consequently, the optical recording medium having a recording layer made from these organic pigments enables to obtain a high recording sensitivity and a signal modulation degree in the wavelength band of 630 nm to 650 nm.

FIG. 22 shows a characteristic of an optical reflection spectrum of an optical recording medium using a mixture of pigments a3 and j1.

It should be understood that the drawings are not necessarily to scale and that the embodiments are sometimes illustrated by graphic symbols, phantom lines, diagrammatic representations and fragmentary views. In certain instances, details which are not necessary for an understanding of the present invention or which render other details difficult to perceive may have been omitted. It should be understood, of course, that the invention is not necessarily limited to the particular embodiments illustrated herein.

DETAILED DESCRIPTION OF THE PRESENTLY PREFERRED EMBODIMENTS

Hereinafter, description will be directed to embodiments of the present invention with reference to the drawings.

Hereinafter, description will be directed to embodiments of the present invention.

FIG. 1 shows an optical recording medium according to the present invention including a light transmitting substrate 1 on which a recording layer 2, a reflection layer 3, and a protection layer 4 are successively formed.

The recording layer 2 contains an organic pigment as a recording material. When a laser beam is radiated onto this recording layer 2, the organic pigment absorbs the light and heat is generated so as to dissolve the pigment. Because of this dissolution of the pigment, the reflection ratio is locally changed, thus recording an information signal.

According to the present invention, this recording layer 2 contains an organic pigment which is a tri-methine pigment compound a, b, or c having a predetermined aromatic ring at both ends. These tri-methine pigments enable to obtain a high reflection ratio and an appropriate optical absorption in the wavelength band of 630 nm to 650 nm and has a small wavelength dependency in this wavelength band, enabling to obtain a stable optical characteristic. Consequently, the optical recording medium using these tri-methine pigments as a recording material enables to obtain a high recording sensitivity and a signal modulation degree in the wavelength band of 630 nm to 650 nm.

Each of these tri-methine pigments can be used solely or in combination. By combining a plurality of types, it is possible to adjust the optical absorption and the reflection ratio in the range of 630 nm to 650 nm.

Moreover, each of these tri-methine pigments may be mixed with a pigment compound d (mono-methine pigment having a predetermined aromatic ring at both ends), a pigment compound e (di-methine pigment having a predetermined aromatic ring at both ends), and a pigment compound f (tri-methine pigment having a predetermined aromatic ring at both ends). Each of the pigment compounds d, e, and f having no absorption in the wavelength band of 630 nm to 650 nm cannot be used solely as a recording material, but can be used as a recording material if mixed with other pigment compounds such as the pigment compounds a, b, and c. Thus, by constituting the recording layer 2 with a plurality of pigment compounds in combination, it is possible to obtain a preferable optical absorption and reflection ratio in the range of 630 nm to 650 nm.

In addition to this, as the organic pigment used for the recording layer 2 may be selected from the following: a

15

pigment compound g (mono-methine pigment having a predetermined aromatic ring at both ends), a pigment compound h (di-methine pigment having a predetermined aromatic ring at both ends), a pigment compound i (tri-methine pigment having a predetermined aromatic ring at both ends), and a pigment compound j (tetra-methine pigment having a predetermined aromatic ring at both ends). Each of these pigment compounds g, h, i, and j can be used in combination with other pigment compounds, so as to reduce the wavelength dependency of the reflection ratio in the range from 630 to 650 nm. Consequently, here, each of the pigment compounds g, h, i, and j is to be used not solely but in combination with other compound(d) as a mixture. For this mixture, it is possible to select two or more from the pigment compounds g, h, i, and j; or to combine the pigment compounds g to j with the pigment compounds a to c; or to combine the pigment compounds g to j with the pigment compounds d to f; or to combine the pigment compounds g to j with the pigment compounds a to c and the pigment compounds d to f. Here, the semiconductor laser used for recording and reproduction of the optical recording medium, has an oscillation wavelength which fluctuates due to fluctuation of production quality or fluctuation of environmental temperature. For this, the reduction in wavelength dependency of the recording layer 2 by mixing the pigment compounds g to j exhibits a great merit to obtain a stable reproduction characteristic.

It should be noted that the aforementioned pigment compounds a to j are shown in Chemical Formulae 191 to 259. Note that Chemical Formulae 191 to 198 (pigments a1 to a8) are examples of the pigment compound a; Chemical formulae 199 to 206 (pigments b1 to b8) are examples of the pigment compound b; Chemical Formulae 207 to 213 (pigments c1 to c7) are examples of the pigment compound c; Chemical Formulae 214 and 215 (pigments d1 and d2) are examples of the pigment compound d; Chemical Formulae 216 to 220 (pigments e1 to e5) are examples of the pigment compound e; Chemical Formulae 221 to 229 (pigments f1 to f9) are examples of the pigment compound f; Chemical Formula 230 (pigment g1) is an example of the pigment compound g; Chemical Formulae 231 to 234 (pigments h1 to h4) are examples of the pigment compound h; Chemical Formulae 235 to 247 (pigments i1 to i13) are examples of the pigment compound i; and Chemical Formulae 248 to 259 (pigments j1 to j12) are examples of the pigment compound j. It should be noted that among these pigments, the pigment a8 has a special merit that it can be solved with a high concentration of 20 weight/volume % or above in a solvent, which enables to easily adjust the pigment solution.

The recording layer 2 is made by using the aforementioned organic pigments as the recording material. Furthermore, as an additive, it is possible to add a chemical substance (deactivating agent) for deactivating a singlet oxygen. As such a chemical substance, there can be exemplified a nickel metal complex compound, copper complex compound, hindered amine compound, aromatic amine compound, aromatic immonium chloride compound, and the like. By using these deactivating agent, it is possible to prevent optical deterioration of the recording layer 2.

As has been described above, the recording layer 2 is formed by using an organic pigment with addition of a deactivating agent, if necessary, solved in an organic solvent so as to prepare a pigment paint which is applied, for example, by way of the spin coat method onto the transparent substrate 1 and dried.

As the solvent for preparing this paint, it is preferable to select a solvent in which the organic pigments and the deactivating agents can be solved with a high dissolution and which will not cause swelling or dissolution of the substrate 1.

For example, the following are appropriate as the solvent: diacetone alcohol, 3-hydroxy-3-methyl-2-butanone, ethylene glycol monomethyl ether, ethylene glycol monoethyl ether, propylene glycol monomethyl ether, propylene glycol monoethyl ether, cyclohexanon, chloroform, 2,3,3,3-tetrafluoro-1-propanol, and the like.

The recording layer 2 preferably has a thickness of 50 to 1000 nm. If the recording layer 2 has a thickness smaller than this range, the heat generated in the recording layer 2 by a laser beam easily reaches the reflection layer 3 and it is impossible to use the laser beam effectively for information recording. Moreover, if the recording layer 2 has a thickness above 1000 nm, the volume in the recording layer through which the laser beam passes is increased and the temperature increase per laser power is decreased. Thus, it becomes difficult to generate an optical change sufficient for information recording.

In the optical recording medium according to the present invention, the recording layer 2 is made by using the aforementioned materials. However, the optical recording medium may have a configuration other than this which is normally used in this type of optical recording medium.

Firstly, the transparent substrate 1 is formed in a disc shape and has a tracking groove or pit formed in a concave-convex configuration on a surface which is brought into contact with the recording layer 2.

As the substrate material, a high molecular material is used such as a polymethacryl resin, polycarbonate resin, polyolefin resin, and the like. These high molecular materials are formed into a substrate shape by way of, for example, injection molding or extrusion molding. Moreover, as the transparent substrate 1, it is also possible to use a glass substrate on which a groove or pit is formed by way of the 2P method (photo-polymer method). It should be noted that an intermediate layer may be formed on the surface of the transparent substrate 1 on which the recording layer 2 is to be formed, for the purpose of protecting the transparent substrate 1 from the pigment paint solvent.

The aforementioned reflection layer 3 is made from a metal such as gold, silver, copper, aluminium, and the like. Each of these metals may be used solely or in combination. The reflection layer 3, for example, is formed by a thin film formation technique such as vacuum deposition, sputtering, ion plating, and the like.

On the optical reflection layer 3 is formed a protection layer 4 which is additionally provided for protecting the recording layer 2 and the reflection layer 3 from corrosive factors and shocks from an external environment.

The protection layer 4 need not be optically transparent and can be made from, for example, an ultraviolet-hardening resin applied by way of spin coating method and hardened by ultraviolet radiation so as to obtain an ultraviolet hardened resin film. Alternatively, it is also possible to use as the material of the protection layer 4, fluororesin, silicon resin, acryl resin, urethane resin, and the like. Moreover, the

protection layer 4 may contain various additives or filler so as to improve the viscosity, shrinkage property, anti-humidity property, and the like.

Moreover, the aforementioned optical recording medium is a single-plate type configuration having a single transparent substrate 1 on which the recording layer 2, an optical absorption layer, and the like are formed. However, the optical recording medium according to the present invention may be a double-plate type having a substrate bonded to a single-plate configuration.

The substrate to be bonded may be a single-plate type disc having a transparent substrate on which a recording layer, a protection layer, and the like are formed. The recording layer may be a recording layer using an organic pigment as a recording material, a metal reflection layer (reproduction-dedicated recording layer) on which an information signal is recorded in advance through a convex-concave pattern. The recording layer may be other than this. Note that in a case of using an organic pigment as the recording material, there should be provided an optical absorption layer as has been described above.

For bonding such a single-plate type disc, the protection layer of a disc can be bonded to the protection layer of the other disc by using an adhesive or both-sided adhesive tape. It should be noted that the adhesive agent used for this bonding may also have the function of the protection layer, omitting the protection layer of the single-plate disc.

Moreover, the substrate to be bonded may be a substrate not contributing to optical information recording, i.e., a substrate not having a recording layer formed. In this case, the substrate need not be optically transparent and may have a trademark printed or have a surface on which letters and the like can be written by a writing tool.

Furthermore, the optical recording medium according to the present invention may have the air-sandwich configuration in which two single-plate discs each having a recording layer of an organic pigment are bonded in such a manner that the recording layers oppose to each other through an air layer.

Next, the following study has been made in order to confirm the effects of the present invention.

PREPARATORY EXPERIMENT 1-1

Examination of Pigment Compound a

As the pigment compound a, we have prepared pigments a1 to a6. In order to check the absorption spectrum of these pigments, each of the pigments was solved in tetrafluoro-propanol to obtain a pigment solution of 3.0 weight/volume %. It should be noted that when the dissolution speed of a pigment was too slow, an ultrasonic washer and a slow mill were used to dissolve the pigment completely.

Each of these pigment solutions obtained is applied onto a glass plate of 3 cm×3 cm by way of spin coat method and dried to form a pigment layer and its absorption spectrum was observed. The pigments a1 to a6 respectively had the absorption spectra shown in FIG. 2. It should be noted that these absorption spectra are normalized at the maximum absorption of the spectra observed.

FIG. 2 shows that the absorption end is shifted to the long wavelength side in the order of the pigment a1, pigment a2, pigment a3, pigment a4, and pigment a5, and the absorption at 640 nm is increased. This shift of the absorption end to the long wavelength side is caused of spread of π electron in the indoline part.

EXAMPLE 1-1

Each of the pigment a4, pigment a5, and pigment a6 was used solely as a recording material to prepare an optical disc as follows.

Firstly, each of the pigments a4, a5, and a6 was dissolved in tetrafluoropropanol to obtain a pigment solution. Note that the concentration of the pigment solution was adjusted so a reflection layer formed layer has a reflection ratio of 50% at the wavelength of 640 nm.

On the other hand, we prepared a polycarbonate disc substrate having a thickness of 0.6 mm and an outer diameter of 120 mm. Note that a guide groove is formed at an interval of 0.8 μm on one side of this disc for tracking of a laser beam during recording.

On this substrate was formed a recording layer by applying a pigment solution by way of spin coat method. It should be noted that a computer was used for quantity control of the pigment solution to be applied and control of the application sequence.

Firstly, the disc was placed with its side having the guide groove upward and with its opposite side chucked on an air suction type chucking table.

While the disc substrate was rotated at 300 rpm, the pigment solution was applied starting at a position slightly out of the outermost circumference of the guide groove toward the innermost circumference of the guide groove. Next, the rotation of the disc substrate was increased to 1500 rpm so as to remove an excess amount of the pigment solution. After this, the rotation was temporarily lowered to 500 rpm and then increased for 15 seconds up to 2000 rpm.

As a result, the pigment solution was spread over the entire disc substrate surface, which was dried to form a recording layer. Note that the thickness of the recording layer formed was determined by measuring the optical concentration: the center film thickness was 100 nm and the thickness deviation was within 10%.

Next, a reflection layer with a thickness of 100 nm was formed on the recording layer by using a resistance heating type vacuum deposition apparatus.

When forming the reflection layer, the portions inside and outside of the area having the guide area were shaded, so that the reflection layer was formed only on the area having the guide groove. Moreover, in order to obtain a uniform thickness, the deposition was carried out while rotating the substrate. The vacuum degree during the deposition was 10–6 Torr and the deposition speed and thickness were controlled by using a quartz oscillation film thickness meter.

Next, a protection layer was formed by applying an ultraviolet-ray hardening resin (trade name Kayarad OVD-005 produced by Nihon Kayaku Co., Ltd.) onto the reflection layer by way of spin coat method. The spin coat method was carried out as follows.

Firstly, the disc substrate was placed with its surface having the guide groove upward and a rear surface portion corresponding to inside of the guide groove chucked by an air suction type chucking table.

While the disc substrate was rotated at 300 rpm, the ultraviolet-ray hardening resin was applied starting at a position slightly outside of the outermost circumference of the guide groove toward the innermost circumference of the guide groove. Subsequently, the rotation of the disc substrate was increased to 1500 rpm so as to remove an excess quantity of the ultraviolet-ray hardening resin.

As a result, the ultraviolet-ray hardening resin was applied over the entire surface of the disc substrate. It should

be noted that for radiation of ultraviolet rays, we used a mercury lamp of 80W/cm straight pipe type. By this, the ultraviolet-ray hardening resin was hardened by 5 seconds of radiation.

5 On the protection layer thus formed, a double-sided adhesive film was adhered to bond the polycarbonate substrate of 0.6 mm thickness, thus obtaining an optical disc.

The optical discs prepared had the optical reflection spectra shown in FIG. 3, FIG. 4, and FIG. 5. It should be noted that FIG. 3 shows the optical reflection spectrum of the optical disc prepared by using the pigment a4; FIG. 4 shows the optical reflection spectrum of the optical disc prepared by using the pigment a5; and FIG. 5 shows the optical reflection spectrum of the optical disc prepared by using the pigment a5. Thus, for all of these optical discs, it was possible to obtain a reflection ratio of about 50% in the wavelength of 640 nm.

Next, for these optical discs, a recording test was carried out by using a red semiconductor laser of 640 nm as a light source. Note that this recording test was carried out under the following conditions.

Recording/reproduction layer:

Red semiconductor laser of 640 nm

Objective lens numerical aperture: 0.6

Linear velocity: 1.8 m/second

Recording signal: EFM+signal

Shortest bit length: 0.3 μm

Under these conditions, the recording operation was carried out while increasing the laser power step by step. In the case of the optical disc using the pigment a4, the recording was actually started with a laser power of about 6.5 mW. The signal modulation was increased as the laser power increased. With the laser power of 12 mW, it was possible to obtain signal modulation of 60% or above. For reference, FIG. 6 shows an eye pattern obtained when a signal was reproduced with the laser power of 12 mW.

Almost similarly, in the case of the optical disc using the pigment a5, recording was actually started with the laser power of about 6.0 mW. The signal modulation was increased as the laser power increased, and with the laser power of 11 mW, it was possible to obtain signal modulation of 60% or above.

In the case of the optical disc using the pigment a6, recording was actually started with the laser power of about 6.5 mW. The signal modulation increased as the laser power increased and with the laser power of 10 mW, it was possible to obtain signal modulation of 60% or above.

Furthermore, for each of the optical disc using the pigment a4, the optical disc using the pigment a5, and the optical disc using the pigment a6, reproduction was carried out with the wavelength of 650 nm. Similarly in the case of 640 nm, it was possible to obtain a preferable reproduction signal.

From the aforementioned, it can be understood that in the optical discs using the pigment a4, the pigment a5, and the pigment a6 as the recording material, it is possible to carry out recording and reproduction with 640 nm and that the wavelength dependency is small in the vicinity of 640 nm, enabling to obtain a stable reproduction.

It should be noted that the identical test with the wavelength of 640 nm was carried out for the optical discs using the pigments a1, a2, a3, the pigment a7, and the pigment a8 as the recording material. In each of these optical discs, recording was actually started with a laser power of 6.0 to 6.5 mW and signal modulation of 60% or above was obtained with a laser power of about 11 mW. Moreover,

reproduction with a wavelength of 650 nm resulted in similar reproduction characteristics.

EXAMPLE 1-2

Among the pigment compounds a, a mixture of pigments a1 and a2 and a mixture of pigment a3 and a5 were respectively used as the recording material to prepare optical discs as follows.

The pigment a1 and the pigment a2 were mixed with weight ratio of 1:3 and dissolved in a tetrafluoropropanol to obtain a pigment solution. The pigment a3 and the pigment a5 were mixed with weight ratio of 5:1 and dissolved in tetrafluoropropanol to obtain a pigment solution. The concentration of the pigment solutions was adjusted so that a reflection layer formed enables to obtain a reflection ratio of 50% at 640 nm.

These solutions were used to prepare optical discs in the same way as in Example 1.

The optical discs prepared had optical reflection spectra shown in FIG. 7 and FIG. 8. Note that FIG. 7 shows an optical reflection spectrum of the optical disc prepared using the mixture of the pigments a1 and a2; and FIG. 8 shows an optical reflection spectrum of the optical disc prepared by using the mixture of the pigments a3 and a5. In each of these optical discs, a reflection ratio of about 50% was obtained at wavelength of 640 nm.

Next, a recording test was carried out for each of these optical discs by using the red semiconductor laser of 640 nm under the same conditions as Example 1.

As a result, in the optical disc using the mixture of the pigments a1 and a2, recording was actually started with a laser power of about 6.5 mW. The signal modulation increased as the laser power increased and with a laser power of 12 mW, signal modulation of 60% or above was obtained.

Almost similarly, in the optical disc using the mixture of the pigments a3 and a5, recording was actually started with a laser power of about 6.0 mW. The signal modulation increased as the laser power increased and with a laser power of 10 mW it was possible to obtain signal modulation of 60% or above.

Furthermore, reproduction with a wavelength of 650 nm for each of these optical discs resulted in a preferable reproduction signal like in the recording/reproduction with 640 nm.

As can be understood from the aforementioned, in the optical discs using mixtures of the pigment compounds a, it is possible to obtain recording/reproduction with 640 nm and the wavelength dependency is small in the vicinity of 640 nm, enabling to obtain a stable reproduction.

PREPARATORY EXPERIMENT 2-1

Examination of Pigment Compound b

As the pigment compound b, we have prepared pigments b1 and b2. In order to check the absorption spectrum of these pigments, each of the pigments was solved in tetrafluoropropanol to obtain a pigment solution of 3.0 weight/volume %. It should be noted that when the dissolution speed of a pigment was too slow, an ultrasonic washer and a slow mill were used to dissolve the pigment completely.

Each of these pigment solutions obtained was applied onto a glass plate of 3 cm×3 cm by way of spin coat method and dried to form a pigment layer and its absorption spectrum was observed. The pigments b1 and b6 respectively

had the absorption spectra shown in FIG. 9. It should be noted that these absorption spectra are normalized at the maximum absorption of the spectra observed.

The pigments b1 and b2 are compound having a thiazoline skeleton within a molecule. When compared to the absorption spectra of the pigments a1 and a2 having an indoline skeleton in a molecule shown in FIG. 2, the absorption end at the longer wavelength side decreases moderately. This means that the pigments b1 and b2 are useful as recording materials for recording with a 640 nm red semiconductor laser. It should be noted that in addition to these pigments, we observed absorption spectra of pigments b3 to b8 which also enabled to obtain an absorption spectrum having an absorption end extending to or above 640 nm.

EXAMPLE 2-1

Each of the pigment b1 and pigment b2 was used solely as a recording material to prepare an optical disc as follows.

Each of the pigments b1 and b2 was dissolved in tetrafluoropropanol to obtain a pigment solution. Note that the concentration of the pigment solution was adjusted so a reflection layer formed layer has a reflection ratio of 50% at the wavelength of 640 nm.

These pigment solutions were used to prepare optical discs in the same way as in Example 1.

The optical discs prepared had the optical reflection spectra shown in FIG. 10 and FIG. 11. It should be noted that FIG. 10 shows the optical reflection spectrum of the optical disc prepared by using the pigment b1; and FIG. 11 shows the optical reflection spectrum of the optical disc prepared by using the pigment b2. Thus, for each of these optical discs, it was possible to obtain a reflection ratio of about 50% in the wavelength of 640 nm.

Next, for these optical discs, a recording test was carried out by using a red semiconductor laser of 640 nm as a light source under the same conditions as in Example 1.

As a result, in the optical disc using the pigment b1, recording was actually started with the laser power of about 7 mW. The signal modulation was increased as the laser power increased, and with the laser power of 12 mW, it was possible to obtain signal modulation of 60% or above.

Similarly, in the case of the optical disc using the pigment b2, recording was actually started with the laser power of about 7 mW. The signal modulation increased as the laser power increased and with the laser power of 12 mW, it was possible to obtain signal modulation of 60% or above.

Furthermore, for each of the optical discs, reproduction was carried out with the wavelength of 650 nm. Like in the case of recording with 640 nm, it was possible to obtain a preferable reproduction signal.

From the aforementioned, it can be understood that in the optical discs using the pigment b as the recording material, it is possible to carry out recording and reproduction with 640 nm and that the wavelength dependency is small in the vicinity of 640 nm, enabling to obtain a stable reproduction.

PREPARATORY EXPERIMENT 3-1

Examination of Pigment Compound c

As the pigment compound c, we have prepared pigment c2. In order to check the absorption spectrum of this pigment, the pigment was solved in tetrafluoropropanol to obtain a pigment solution of 3.0 weight/volume %. It should be noted that when the dissolution speed of a pigment was

too slow, an ultrasonic washer and a slow mill were used to dissolve the pigment completely.

The pigment solution obtained was applied onto a glass plate of 3 cm×3 cm by way of spin coat method and dried to form a pigment layer and its absorption spectrum was observed. The pigments c2 had the absorption spectrum shown in FIG. 12. It should be noted that these absorption spectra are normalized at the maximum absorption of the spectra observed.

EXAMPLE 3-1

The pigment c2 was used solely as a recording material to prepare an optical disc as follows.

The pigments c2 was dissolved in tetrafluoropropanol to obtain a pigment solution. Note that the concentration of the pigment solution was adjusted so a reflection layer formed layer has a reflection ratio of 50% at the wavelength of 640 nm.

This pigment solution was used to prepare an optical disc in the same way as in Example 1.

The optical discs prepared had the optical reflection spectra shown in FIG. 13. Thus, this optical disc enabled to obtain a reflection ratio of about 50% in the wavelength of 640 nm.

Next, for this optical disc, a recording test was carried out by using a red semiconductor laser of 640 nm as a light source under the same conditions as in Example 1.

As a result, in the optical disc using the pigment c2, recording was actually started with the laser power of about 6.5 mW. The signal modulation was increased as the laser power increased, and with the laser power of 10 mW, it was possible to obtain signal modulation of 60% or above.

Moreover, for this optical disc, reproduction was carried out with the wavelength of 650 nm. Like in the case of recording with 640 nm, it was possible to obtain a preferable reproduction signal.

From the aforementioned, it can be understood that in the optical discs using the pigment c as the recording material, it is possible to carry out recording and reproduction with 640 nm and that the wavelength dependency is small in the vicinity of 640 nm, enabling to obtain a stable reproduction.

PREPARATORY EXPERIMENT 4-1

Examination of Pigment Compound Mixtures 1

The pigment compound f shows almost no absorption at 640 nm.

Firstly, as the pigment compound f, we prepared pigments f7 to f9. In order to check the absorption spectra of these pigments, each of the pigments was dissolved in tetrafluoropropanol to obtain a pigment solution of 3.0 weight/volume %. It should be noted that when the dissolution speed of a pigment was too slow, an ultrasonic washer and a slow mill were used to dissolve the pigment completely.

Each of the pigment solutions obtained was applied onto a glass plate of 3 cm×3 cm by way of spin coat method and dried to form a pigment layer and its absorption spectrum was observed. The pigments f7 to f9 respectively had the absorption spectra shown in FIG. 14. It should be noted that these absorption spectra are normalized at the maximum absorption of the spectra observed.

FIG. 14 shows that the absorption end is shifted toward the longer wavelength side in the order of the pigment f7, pigment f8, and pigment f9, but there can be seen almost no

absorption at 640 nm. Note that this shift of the absorption end toward the longer wavelength side reflects the spread of π electron in a molecule.

EXAMPLE 4-1

A mixture of pigment a5 and pigment f7 and a mixture of pigment compound b2 and pigment compound f7 were respectively used as the recording material to prepare optical discs as follows.

The pigment a5 and the pigment f7 were mixed with a weight ratio of 10:4.5 and dissolved in tetrafluoropropanol to obtain a pigment solution; and the pigment b2 was mixed with pigment f9 with weight ratio of 10:2.5 and was dissolved in tetrafluoropropanol to obtain a pigment solution.

These pigment solutions were used to prepare optical discs in the same way as in Example 1-1.

The optical discs thus prepared had optical reflection spectra shown in FIG. 15 and FIG. 6, respectively. Note that FIG. 15 shows the optical reflection spectrum of the optical disc using the mixture of pigment a5 and pigment f7; and FIG. 16 shows the optical reflection spectrum of the optical disc using the mixture of pigment b2 and pigment f9. Each of these pigment mixtures enabled to obtain a reflection ratio of about 50% at the wavelength of 640 nm.

Next, for these optical discs, a recording test was carried out by using a red semiconductor laser of 640 nm as a light source under the same conditions as in Example 1-1.

As a result, in the optical disc using the mixture of pigments a5 and f7, recording was actually started with the laser power of about 7 mW. The signal modulation was increased as the laser power increased, and with the laser power of 12 mW, it was possible to obtain signal modulation of 60% or above.

Almost similarly, in the optical disc using the mixture of the pigments b2 and f9, recording actually started with the laser power of about 6 mW. The signal modulation increased as the laser power increased. With the laser power of 12 mW, it was possible to obtain signal modulation of 60% or above.

Moreover, reproduction was carried out with the wavelength changed to 650 nm. Like in the case of recording with 640 nm, it was possible to obtain a preferable reproduction signal.

From the aforementioned, it can be understood that although the pigment compound f shows no absorption at 640 nm, if mixed with the pigment compound a or pigment compound b, it can be used to carry out recording/reproduction at 640 nm. Moreover, in the optical discs using these mixtures as the recording material, the wavelength dependency is small in the vicinity of 640 nm, enabling to obtain a stable reproduction.

It should be noted that as polymethine pigment compound not having absorption at 640 nm, there can be exemplified a pigment d1 (absorption maximum wavelength 525 nm), pigment d2 (absorption maximum wavelength 559 nm), pigment e3 (absorption maximum wavelength 550 nm), and pigment f3 (absorption maximum wavelength 527 nm). Each of these pigments was mixed with the pigment a5 to obtain mixtures as the recording material of optical discs for carrying out a recording test. Each of the optical discs resulted in that the laser power required for recording was in the range of 10 to 12 mW, causing no practical problem for recording. However, it was observed that as the absorption maximum wavelength is shifted to the longer wavelength side, the laser power required for recording is reduced.

PREPARATORY EXPERIMENT 5-1

Examination of Pigment Compound Mixtures

The pigment compound i is an organic pigment showing absorption at 640 nm, and when mixed with other pigment

compound, exhibits an effect to reduce the wavelength dependency in the vicinity of 640 nm.

Firstly, as the pigment compound i, we prepared pigments i4 to i7. In order to check the absorption spectra of these pigments, each of the pigments was dissolved in tetrafluoropropanol to obtain a pigment solution of 3.0 weight/volume %. It should be noted that when the dissolution speed of a pigment was too slow, an ultrasonic washer and a slow mill were used to dissolve the pigment completely.

Each of the pigment solutions obtained was applied onto a glass plate of 3 cm×3 cm by way of spin coat method and dried to form a pigment layer and its absorption spectrum was observed. The pigments i4 and i7 respectively had the absorption spectra shown in FIG. 17. It should be noted that these absorption spectra are normalized at the maximum absorption of the spectra observed.

FIG. 17 shows that the absorption spectra of these pigments i4 and i7 are characterized in that the absorption end of the longer wavelength side extends over 700 nm toward the longer wavelength side.

EXAMPLE 5-1

A mixture of pigment a3 and pigment i4 and a mixture of pigment compound f9 and pigment compound i7 were respectively used as the recording material to prepare optical discs as follows.

The pigment a3 and the pigment i4 were mixed with a weight ratio of 10:9.5 and dissolved in tetrafluoropropanol to obtain a pigment solution; and the pigment f9 was mixed with pigment i7 with weight ratio of 10:8 and dissolved in tetrafluoropropanol to obtain a pigment solution.

These pigment solutions were used to prepare optical discs in the same way as in Example 1-1.

The optical discs thus prepared had optical reflection spectra shown in FIG. 18. Note that FIG. 18 shows the optical reflection spectrum of the optical disc using the mixture of pigment a3 and pigment i4; and FIG. 19 shows the optical reflection spectrum of the optical disc using the mixture of pigment f9 and pigment i7.

Firstly, in the case of the optical reflection spectrum obtained from the use of the mixture of pigments a3 and i4 shown in FIG. 18, it can be understood that the reflection ratio increases toward the longer wavelength side but this increase is slowed in the vicinity of 640 nm.

Moreover, in the optical reflection spectrum obtained from the use of the mixture of pigments f9 and i7 shown in FIG. 19, the reflection ratio increases toward the longer wavelength side but the increase is suppressed in the vicinity of 640 nm.

Thus, it can be understood that when a pigment compound is mixed with pigment i4 or pigment i7, the wavelength dependency of the reflection ratio is reduced in the vicinity of 640 nm. In particular, the combination of pigments a3 and i4 remarkably reduces the wavelength dependency of the reflection ratio.

Next, for these optical discs, a recording test was carried out by using a red semiconductor laser of 640 nm as a light source under the same conditions as in Example 1-1.

As a result, in the optical disc using the mixture of pigments a3 and i4, recording was actually started with the laser power of about 6 mW. The signal modulation was increased as the laser power increased, and with the laser power of 10 mW, it was possible to obtain signal modulation of 60% or above.

Almost similarly, in the optical disc using the mixture of the pigments f8 and i7, recording actually started with the

laser power of about 7 mW. The signal modulation increased as the laser power increased. With the laser power of 11 mW, it was possible to obtain signal modulation of 60% or above.

Moreover, reproduction was carried out with the wavelength changed to 650 nm. Like in the case of recording with 640 nm, it was possible to obtain a preferable reproduction signal.

From the aforementioned, it can be understood that in an optical disc using a mixture of pigments i4 and i7 with other pigment compound, the wavelength dependency is small in the vicinity of 640 nm, enabling to obtain a stable reproduction.

It should be noted that a mixture containing the pigment compound g, pigment compound h, or pigment compound i other than those used here also has the effect to reduce the wavelength dependency in the vicinity of 640 nm.

PREPARATORY EXPERIMENT 6-1

Examination of Pigment Compound Mixtures 3

The pigment compound j is an organic pigment showing absorption at 640 nm, and when mixed with other pigment compound, exhibits an effect to reduce the wavelength dependency in the vicinity of 640 nm.

Firstly, as the pigment compound i, we prepared pigments ji to j6. In order to check the absorption spectra of these pigments, each of the pigments was dissolved in tetrafluoropropanol to obtain a pigment solution of 3.0 weight/volume %. It should be noted that when the dissolution speed of a pigment was too slow, an ultrasonic washer and a slow mill were used to dissolve the pigment completely.

Each of the pigment solutions obtained was applied onto a glass plate of 3 cm×3 cm by way of spin coat method and dried to form a pigment layer and its absorption spectrum was observed. The pigments j1 and j6 respectively had the absorption spectra shown in FIG. 20. It should be noted that these absorption spectra are normalized at the maximum absorption of the spectra observed.

FIG. 20 shows that the absorption spectra of these pigments ji and j6 are characterized in that the absorption end of the longer wavelength side extends over 700 nm toward the longer wavelength side.

EXAMPLE 6-1

A mixture of pigment compounds a1 and j6, and a mixture of pigment compounds a3 and j1 were respectively used as the recording material to prepare optical discs as follows.

The pigment a1 and the pigment j6 were mixed with a weight ratio of 15:14 and dissolved in tetrafluoropropanol to obtain a pigment solution; and the pigment a3 was mixed with pigment j1 with weight ratio of 10:5 and dissolved in tetrafluoropropanol to obtain a pigment solution.

These pigment solutions were used to prepare optical discs in the same way as in Example 1-1.

The optical discs thus prepared had optical reflection spectra shown in FIG. 21 and FIG. 22. Note that FIG. 21 shows the optical reflection spectrum of the optical disc using the mixture of pigment a1 and pigment j6; and FIG. 22 shows the optical reflection spectrum of the optical disc using the mixture of pigment a3 and pigment j1.

Firstly, in the case of the optical reflection spectrum obtained from the use of the mixture of pigments a1 and j6 shown in FIG. 21, it can be understood that the reflection ratio increases toward the longer wavelength side but this increase is slowed down in the vicinity of 640 nm.

Moreover, in the optical reflection spectrum obtained from the use of the mixture of pigments a3 and j1 shown in FIG. 22, the reflection ratio increases toward the longer wavelength side but the increase is suppressed in the vicinity of 640 nm.

Thus, it can be understood that when a pigment compound is mixed with pigment ji or pigment j6, the wavelength dependency of the reflection ratio is reduced in the vicinity of 640 nm.

Next, for these optical discs, a recording test was carried out by using a red semiconductor laser of 640 nm as a light source under the same conditions as in Example 1-1.

As a result, in the optical disc using the mixture of pigments a1 and j6, recording was actually started with the laser power of about 6.5 mW. The signal modulation was increased as the laser power increased, and with the laser power of 10 mW, it was possible to obtain signal modulation of 60% or above.

Almost similarly, in the optical disc using the mixture of the pigments f8 and i7, recording actually started with the laser power of about 7 mW. The signal modulation increased as the laser power increased. With the laser power of 10.5 mW, it was possible to obtain signal modulation of 60% or above.

Moreover, reproduction was carried out with the wavelength changed to 650 nm. Like in the case of recording with 640 nm, it was possible to obtain a preferable reproduction signal.

In an optical disc using a mixture of pigment j with other pigment compound, the wavelength dependency is small in the vicinity of 640 nm, enabling to obtain a stable reproduction.

From the above description, it is apparent that the objects of the present invention have been achieved. While only certain embodiments have been set forth, alternative embodiments and various modifications will be apparent from the above description to those skilled in the art. These and other alternatives are considered equivalents and within the spirit and scope of the present invention.

What is claimed is:

1. An optical recording medium comprising:

a recording layer and an optical reflection layer formed on a light transmitting substrate, wherein the recording layer consists of a trimethine pigment expressed by Structural Formula I, a trimethine pigment expressed by Structural Formula II, and a trimethine pigment expressed by Structural Formula III as follows:

Structural Formula I:

wherein X— is selected from the group consisting of Br⁻, I⁻, ClO₄⁻, BF₄⁻, PF₆⁻, and SbF₆⁻; wherein, A¹ is an atomic group selected from the group consisting of Chemical Formulae 1 through 3, and B¹ is an atomic group selected from the group consisting of Chemical Formula 4;

Chemical Formula 1

Chemical Formula 2

Chemical Formula 3

Chemical Formula 4

25

wherein, R¹ is selected from the group consisting of alkyl group, alkoxy group, and aryl group; R² and R³ are selected from the group consisting of hydrogen atom, alkyl group, alkoxy group, amino group, nitro group, cyano group, aryl group, alkoxy carbonyl group, sulfonylalkyl group, and halogen atom; n is 1 or 2; m is 1, 2, 3, or 4;

Structural Formula II:

35

wherein X— is selected from the group consisting of Br—, I—, ClO₄⁻, BF₄⁻, PF₆⁻, and SbF₆⁻; A² is an atomic group selected from the group consisting of Chemical Formulae 5 through 8; and B² is an atomic group selected from the group consisting of Chemical Formula 9; wherein Y¹ is selected from the group consisting of hydrogen atom, alkyl group, or halogen atom,

Chemical Formula 5

39

-continued

Chemical Formula 6

Chemical Formula 7

Chemical Formula 8

Chemical Formula 9

wherein, R⁴ is selected from the group consisting of alkyl group, alkoxy group, and aryl group; wherein, R⁵ and R⁶ are selected from the group consisting of hydrogen atom, alkyl group, alkoxy group, amino group, vitro group, cyano group, aryl group, alkoxy carbonyl group, sulfonylalkyl group, and halogen atom; when a molecule contains a plurality of R⁵ or R⁶, the R⁵ or R⁶ may be either identical substituents or different substituents; n is 1 or 2; m is 1, 2, 3, or 4;

Structural Formula III:

X-

wherein X— is selected from the group consisting of Br—, I—, ClO₄⁻, BF₄⁻, PF₆⁻, and SbF₆⁻; A³ is an atomic group selected from the group consisting of Chemical Formulae 10 to 13; B³ is an atomic group selected from the group consisting of Chemical Formulae 14 and 15; Y² is selected from the group consisting of hydrogen atom, alkyl group, or halogen atom;

Chemical Formula 10

40

Chemical Formula 11

Chemical Formula 12

Chemical Formula 13

Chemical Formula 14

Chemical Formula 15

wherein, R¹ is selected from the group consisting of alkyl group, alkoxy group, and aryl group; R⁸ and R⁹ are selected from the group consisting of hydrogen atom, alkyl group, alkoxy group, amino group, nitro group, cyano group, aryl group, alkoxy carbonyl group, sulfonylalkyl group, and halogen atom; n is 1 or 2; m is 1, 2, 3, or 4;

a singlet oxygen quencher added to the pigments to deactivate singlet oxygen, the singlet oxygen quencher is selected from the group consisting of a nickel metal complex compound, a copper complex compound, a hindered amine compound, an aromatic amine compound, and an aromatic immonium chloride compound;

the recording layer having a thickness of 50 to 1000 nm; wherein the recording layer is capable of recording and reproduction with a laser beam having a wavelength from 630 nm to 650 nm; and

wherein the optical recording medium has a signal modulation degree of 60% or higher and an unrecorded area has a reflection ratio of approximately 50% when measured with a laser beam having a wavelength of 640 nm.

2. An optical recording medium comprising a recording layer and an optical reflection layer formed on a light transmitting substrate, wherein the recording layer consists of first dye expressed by Structural Formula VII, second dye

expressed by Structural Formula VIII, a third dye expressed by Structural Formula IX, and a fourth dye expressed by Structural Formula X as follows:

Structural Formula VII:

wherein X— is selected from the group consisting of Br—, I—, ClO₄⁻, BF₄⁻, PF₆⁻, and SbF₆⁻; A⁷ is an atomic group expressed by Chemical Formula 31; B⁷ is an atomic group expressed by Chemical Formula 32

Chemical Formula 31

Chemical Formula 32

wherein, R²⁰ is selected from the group consisting of alkyl group, alkoxy group, and aryl group; R²¹ and R²² are selected from the group consisting of hydrogen atom, alkyl group, alkoxy group, amino group, nitro group, cyano group, aryl group, alkoxy carbonyl group, sulfonylalkyl group, and halogen atom; n is 1 or 2; m is 1, 2, 3, or 4;

Structural Formula VIII:

wherein X— is selected from the group consisting of Br—, I—, ClO₄⁻, BF₄⁻, PF₆⁻, and SbF₆⁻; A⁸ is an atomic group selected from the group consisting of Chemical Formulae 33 to 36; B⁸ is an atomic group expressed by Chemical Formula 37;
