(57) **ABSTRACT**

An integrated circuit package includes a substrate having
conductive traces therein. A first semiconductor die is
mounted in a die-down configuration to a first surface of the
substrate. A second semiconductor die is mounted to a
backside of the first semiconductor die. A plurality of
connectors electrically connect the first semiconductor die to
portions of the conductive traces of the substrate and a
plurality of wire bonds connect the second semiconductor
die to other portions of the conductive traces of the substrate.
An encapsulant encapsulates the wire bonds and covers at
least a portion of the first surface of the substrate and the
second semiconductor die. A ball grid array is disposed on
a second surface of the substrate, bumps of the ball grid
array being connected with the conductive traces.

STACKED SEMICONDUCTOR PACKAGE AND METHOD OF MANUFACTURING THE SAME

FIELD OF THE INVENTION

The present invention relates in general to integrated circuit packaging, and more particularly to a stacked semiconductor die ball grid array package.

BACKGROUND OF THE INVENTION

High performance integrated circuit (IC) packages are well known in the art. Improvements in IC packages are driven by industry demands for increased thermal and electrical performance and decreased size and cost of manufacture.

Dynamic random access memory (DRAM) chips are commonly used in conjunction with flash memory chips in, for example, cellular phones, personal digital assistants (PDAs) and digital cameras. In particular, the DRAM chip is packaged in a single semiconductor package and mounted to a printed circuit board for use in a suitable application. Similarly, the flash memory chip is packaged in a single semiconductor package and is then mounted to the printed circuit board, adjacent the DRAM chip. The printed circuit board provides electrical connections for the two chips when assembled. Clearly, these two packages suffer from many disadvantages, including excessive space required for mounting two separate packages. Also, it is desirable to decrease printed circuit board assembly time and cost.

In one particular improvement to the above-described prior art, DRAM chips and flash memory chips have been encapsulated in a single package, in side-by-side relation to each other. Thus, a single, larger package is mounted to the printed circuit board on assembly. While this package provides the advantage of mounting only a single package containing both the DRAM and flash memory chips adjacent to each other, the package footprint is very large. It is desirable to reduce the package footprint and thereby reduce the area of the package on the printed circuit board.

It is therefore an object of an aspect of the present invention to provide an integrated circuit package and method of manufacturing the package that obviates or mitigates at least some of the disadvantages of the prior art.

SUMMARY OF THE INVENTION

In one aspect of the present invention, there is provided an integrated circuit package including a substrate having conductive traces therein. A first semiconductor die is mounted in a die-down configuration to a first surface of the substrate. A second semiconductor die is mounted to a backside of the first semiconductor die. A plurality of connectors electrically connect the first semiconductor die to portions of the conductive traces of the substrate and a plurality of wire bonds connect the second semiconductor die to other portions of the conductive traces of the substrate. An encapsulant encapsulates the wire bonds and covers at least a portion of the first surface of the substrate and the second semiconductor die. A ball grid array is disposed on a second surface of the substrate, bumps of the ball grid array being connected with the conductive traces.

In another aspect, there is provided a process for fabricating an integrated circuit package. The process includes: mounting a first semiconductor die in a die-down configuration, over a cavity in a substrate, the substrate

2

including conductive traces therein; mounting a second semiconductor die to a backside of the first semiconductor die; wire bonding the second semiconductor die to portions of the conductive traces of the substrate; encapsulating the wire bonds between the second semiconductor die and the conductive traces of the substrate, in an encapsulant; wire bonding the first semiconductor die to other portions of the conductive traces of the substrate; encapsulating the wire bonds between the first semiconductor die and the substrate; and forming a ball grid array on a second side of the substrate, bumps of the ball grid array being electrically connected to ones of the conductive traces.

In one aspect, the first semiconductor die is a dynamic random access memory (DRAM) chip and the second semiconductor die is a flash memory chip. Advantageously, the second semiconductor die is stacked on the first semiconductor die, thereby providing a package including both semiconductor dice and having a smaller footprint than the conventional packages. Thus, the package requires less area when mounted on the motherboard, thereby aiding in reducing the size of the motherboard.

BRIEF DESCRIPTION OF THE DRAWINGS

The invention will be better understood with reference to the drawings and the following description, in which:

FIG. 1 is a sectional side view of an integrated circuit package according to an embodiment of the present invention;

FIGS. 2A to 2J show processing steps for fabricating the integrated circuit package of FIG. 1;

FIG. 3 is a sectional side view of an integrated circuit package according to another embodiment of the present invention; and

FIGS. 4A to 4K show processing steps for fabricating an integrated circuit package according to another embodiment of the present invention.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

Reference is first made to FIG. 1, which shows a sectional side view of an integrated circuit package indicated generally by the numeral 20. The integrated circuit package 20 includes a substrate 22 with conductive traces therein. A first semiconductor die 24 is mounted in a die-down configuration to a first surface 26 of the substrate 22. A second semiconductor die 28 is mounted to a backside of the first semiconductor die 24. A plurality of connectors 30 electrically connect the first semiconductor die 24 to portions of the conductive traces of the substrate 22 and a plurality of wire bonds 32 connect the second semiconductor die 28 to other portions of the conductive traces of the substrate 22. An encapsulant 34 encapsulates the wire bonds 32 and covers at least a portion of the first surface of the substrate 22 and the second semiconductor die 24. A ball grid array of solder balls 36 is disposed on a second surface 38 of the substrate 22, solder balls 36, also referred to as bumps, of the ball grid array being connected with the conductive traces of the substrate 22.

The integrated circuit package 20 will now be described in more detail with reference to FIGS. 2A to 2I to describe processing steps for fabricating the integrated circuit package 20, in accordance with an embodiment of the present invention. Referring first to FIG. 2A, the substrate 22 of a bismaleimide triazine (BT) resin/glass epoxy printed circuit board is shown. The substrate 22 includes conductive metal

3

or alloy traces that provide conductive paths for signal transfer. The conductive traces are patterned during manufacture of the substrate **22**. The substrate manufacturing and the patterning of the conductive traces are well known and well understood by those skilled in the art. The substrate **22** is in the form of a strip for producing a number of BGA units. Only one such unit is depicted in FIG. **2A**, portions of adjacent units being shown by stippled lines. The present discussion describes the fabrication of a single integrated circuit package **20** for the purpose of simplicity only and it will be understood that the package **20** is preferably gang fabricated.

Referring to FIG. **2B**, a cavity is created in the substrate **22** by, for example, mechanical punching. Other suitable methods of creating a cavity in the substrate **22**, are possible.

After creation of the cavity in the substrate **22**, the first semiconductor die **24**, a dynamic random access memory (DRAM) chip, is fixed to the substrate **22** such that the first semiconductor die **24** spans the cavity, as shown in FIG. **2C**. The first semiconductor die **24** is fixed to the substrate **22** using a suitable adhesive, such as a die attach epoxy, followed by epoxy curing. As previously stated, the first semiconductor die **24** is fixed to the substrate **22** in a die-down configuration. In other words, the semiconductor die **24** is fixed to the substrate **22** such that the conductive pad array of the semiconductor die **24** faces into the cavity of the substrate **22**. Care is taken to inhibit the flow of adhesive onto the pads of the conductive pad array during attachment of the semiconductor die **24**.

Next, the second semiconductor die **28**, a flash memory chip, is fixed to the backside of the first semiconductor die **24**, as shown in FIG. **2D**. The second semiconductor die **28** is fixed to the first semiconductor die **24**, using a suitable adhesive, such as a die attach epoxy, followed by epoxy curing. The second semiconductor die **28** is fixed to the first semiconductor die **24** in a die-up configuration, such that the conductive pad array of the second semiconductor die **28** is on the opposite side of conductive pad array of the first semiconductor die **24**. Clearly the conductive pad array of the second semiconductor die **28** faces the opposite direction as the conductive pad array of the first semiconductor die **24**.

Wire bonds **32** are then bonded between the conductive pads of the array of the second semiconductor die **28** and portions of some of the conductive traces on the first surface **26** of the substrate **22** (FIG. **2E**).

After wire bonding, the wire bonds **32** are encapsulated in an overmold compound, referred to herein above as the encapsulant **34**. As shown in FIG. **2F**, the overmold compound **34** encapsulates an upper portion of the package **20**, including the first surface **26** of the substrate **22**, the wire bonds and the second semiconductor die **28**. Thus, the wire bonds **32** as well as the first surface **26** of the substrate **22** and the second semiconductor die **28** are protected.

Next, wire bonds, also referred to herein above as connectors **30** are bonded between the conductive pads of the array of the first semiconductor die **24** and portions of some of the conductive traces on the second surface **38** of the substrate **22** (FIG. **2G**).

After wire bonding, the wire bond connectors **30** are encapsulated in a potting material **40**. As will be understood by those skilled in the art, a potting material is a liquid encapsulant, usually epoxy-based, and is typically applied by syringe and needle dispensing. As shown in FIG. **2H**, the potting material **40** fills the cavity in the substrate **22** and covers the wire bond connectors **30**, the exposed portion of the first semiconductor die **24**, and a portion of the second

4

surface **38** of the substrate **22**. Clearly, the potting material **40** provides protection for the wire bond connectors **30**, the first semiconductor die **24**, and the portion of the second surface **38** of the substrate **22**.

The ball grid array in the form of solder balls **36**, also referred to as solder bumps, is formed on the second surface **38** of the substrate **22** by conventional positioning (FIG. **2I**). To attach the solder balls **36**, a flux is added to the solder balls **36** prior to placement and, after placement, the solder balls **36** are reflowed using known reflow techniques. The solder balls are thereby connected to the conductive traces of the substrate **22** and through the connectors **30** and the wire bonds **32**, to the first and second semiconductor dice **24**, **28**, respectively. The solder balls **36** provide signal and power connections as well as ground connections for the semiconductor dice **24**, **28**.

Singulation of the individual ball grid array (BGA) units from the strip is then performed either by saw singulation or die punching, resulting in the configuration shown in FIG. **2J**. Thus, the individual package **20** is isolated from other packages.

Reference is now made to FIG. **3** to describe an integrated circuit package **20** according to an alternative embodiment of the present invention. In this embodiment a heat sink **42** is included in the package **20** for conducting heat away from the second semiconductor die. The heat sink **42** is molded into the package during encapsulation in the overmold compound **34**. As will be understood by those skilled in the art, the heat sink **42** is molded into the package by loading the heat sink **42** into the mold in strip format and aligning using appropriate locating pins in the mold tooling.

Reference is now made to FIGS. **4A** to **4K** to describe a process for manufacturing an integrated circuit package **20** in which a dummy silicon chip **43** is attached to the second semiconductor die **28** prior to encapsulation, in accordance with still another embodiment of the present invention. FIGS. **4A** to **4D** are similar to FIGS. **2A** to **2D** and therefore need not be further described herein. The dummy silicon chip **43** is attached to the second semiconductor die using a thermally conductive, electrically insulative epoxy (FIG. **4E**). Next, the wire bonds **32** are bonded between the conductive pads of the array of the second semiconductor die **28** and the portions of some of the conductive traces on the first surface **26** of the substrate **22** (FIG. **4F**). After wire bonding, the heat sink **42** is molded into the package during encapsulation in the overmold compound **34** such that the heat sink **42** is in contact with the dummy silicon chip **43** (FIG. **4G**). FIGS. **4H** to **4K** are similar to FIGS. **2G** to **2J**, respectively, and therefore need not be further described herein.

The dummy silicon chip **43** has high thermal conductivity and similar thermo-mechanical properties to the semiconductor die. As shown, the dummy silicon chip **43** is in contact with both the second semiconductor chip **28** and the heat sink **42**. A conductive thermal path is thereby provided from the second semiconductor die **28**, through the dummy silicon chip **43** and to the heat sink **42**.

A specific embodiment of the present invention has been shown and described herein. However, variations and modifications to these embodiments may occur to those skilled in the art. For example, the substrate is not limited to the BT/resin glass epoxy printed circuit board as other suitable laminate substrate materials can be employed. Other variations and modifications may occur to those skilled in the art. All such modifications and variations are believed to be within the sphere and scope of the present invention.

5

What is claimed is:

1. An integrated circuit package comprising:

a substrate having conductive traces therein, the substrate including a cavity therein;

a first semiconductor die mounted in a die-down configuration to a first surface of said substrate such that said first semiconductor die spans said cavity;

a second semiconductor die mounted to a backside of said first semiconductor die;

a first plurality of wire bonds electrically connecting said first semiconductor die to portions of said conductive traces of said substrate;

a second plurality of wire bonds connecting said second semiconductor die to other portions of said conductive traces of said substrate;

an encapsulant encapsulating said second plurality of wire bonds and covering at least a portion of said first surface of said substrate and said second semiconductor die;

a ball grid array disposed on a second surface of said substrate, bumps of said ball grid array being connected with said conductive traces;

a second encapsulant, encapsulating said first plurality of wire bonds; and

a dummy silicon die disposed on said second semiconductor die.

2. The integrated circuit package according to claim **1**, wherein the second plurality of wire bonds connect said second semiconductor die to said other portions of said conductive traces, said other portions being disposed on said first side of said substrate.

3. The integrated circuit package according to claim **1**, wherein the first plurality of wire bonds connect said first semiconductor die to portions of said conductive traces, said portions of said conductive traces being disposed on a second side of said substrate.

4. The integrated circuit package according to claim **1**, further comprising a heat sink, disposed in said encapsulating material for conducting heat away from said second semiconductor die.

5. The integrated circuit package according to claim **1**, further comprising a heat sink disposed in said encapsulating material and in contact with said dummy silicon die for conducting heat away from said second semiconductor die.

6. The integrated circuit package according to claim **5**, wherein said heat sink is disposed on a portion of said second semiconductor die.

7. An integrated circuit package comprising:

a substrate having conductive traces therein;

a first semiconductor die mounted in a die-down configuration to a first surface of said substrate;

a second semiconductor die mounted to a backside of said first semiconductor die;

a plurality of connectors electrically connecting said first semiconductor die to portions of said conductive traces of said substrate;

a plurality of wire bonds connecting said second semiconductor die to other portions of said conductive traces of said substrate;

an encapsulant encapsulating said wire bonds and covering at least a portion of said first surface of said substrate and said second semiconductor die; and

a ball grid array disposed on a second surface of said substrate, bumps of said ball grid array being connected with said conductive traces,

wherein said first semiconductor die is a dynamic random access memory chip and said second semiconductor die is a flash memory chip.

6

8. A process for fabricating an integrated circuit package, comprising:

mounting a first semiconductor die in a die-down configuration, over a cavity in a substrate, the substrate including conductive traces therein;

mounting a second semiconductor die to a backside of said first semiconductor die;

wire bonding said second semiconductor die to portions of said conductive traces of said substrate;

encapsulating the wire bonds between the second semiconductor die and said conductive traces of said substrate, in an encapsulant;

wire bonding said first semiconductor die to other portions of said conductive traces of said substrate;

encapsulating the wire bonds between the first semiconductor die and said substrate; and

forming a ball and array on a second side of the substrate, bumps of the ball grid array being electrically connected to ones of said conductive traces, wherein said mounting a first semiconductor die comprises mounting a dynamic random access memory chip in a die-down configuration, over said cavity in said substrate.

9. The process for fabricating an integrated circuit package according to claim **8**, wherein said mounting a second semiconductor die comprises mounted a flash memory chip to a backside of said dynamic random access memory chip.

10. The process for fabricating an integrated circuit package according to claim **9**, wherein said wire bonding said second semiconductor die to portions of said conductive traces of said substrate includes wire bonding the second semiconductor die to said conductive traces on a first side of said substrate.

11. The process for fabricating an integrated circuit package according to claim **10**, wherein said wire bonding said first semiconductor die to other portions of said conductive traces of said substrate includes wire bonding the first semiconductor die to ones of said conductive traces on the second side of the substrate.

12. A process for fabricating an integrated circuit package, comprising:

mounting a first semiconductor die in a die-down configuration, over a cavity in a substrate, the substrate including conductive traces therein;

mounting a second semiconductor die to a backside of said first semiconductor die;

wire bonding said second semiconductor die to portions of said conductive traces of said substrate;

fixing a dummy silicon die on said second semiconductor die, prior to encapsulating the wire bonds between the second semiconductor die and said conductive traces of said substrate in an encapsulant;

encapsulating the wire bonds between the second semiconductor die and said conductive traces of said substrate, in the encapsulant;

wire bonding said first semiconductor die to other portions of said conductive traces of said substrate;

encapsulating the wire bonds between the first semiconductor die and said substrate; and

forming a ball and array on a second side of the substrate, bumps of the ball grid array being electrically connected to ones of said conductive traces.

13. A process for fabricating an integrated circuit package, comprising:

7

mounting a first semiconductor die in a die-down configuration, over a cavity in a substrate, the substrate including conductive traces therein;

mounting a second semiconductor die to a backside of said first semiconductor die;

fixing a dummy silicon die on said second semiconductor die, prior to wire bonding said second semiconductor die to portions of said conductive traces of said substrate, for conducting heat away from said second semiconductor die;

wire bonding said second semiconductor die to portions of said conductive traces of said substrate;

encapsulating the wire bonds between the second semiconductor die and said conductive traces of said substrate, in an encapsulant;

8

wire bonding said first semiconductor die to other portions of said conductive traces of said substrate;

encapsulating the wire bonds between the first semiconductor die and said substrate; and

forming a ball grid array on a second side of the substrate, bumps of the ball grid array being electrically connected to ones of said conductive traces.

10 **14.** The process for fabricating an integrated circuit package according to claim **13**, wherein encapsulating the wire bonds between the second semiconductor die and said conductive traces of said substrate includes molding a heat sink in contact with said dummy silicon die for conducting heat away from said dummy silicon die.
