A storage pixel sensor disposed on a semiconductor substrate comprises a photodiode having a first terminal coupled to a first potential and a second terminal. A barrier transistor has a first terminal coupled to the second terminal of the photodiode, a second terminal and a control gate coupled to a barrier set voltage. A reset transistor has a first terminal coupled to the second terminal of the barrier transistor, a second terminal coupled to a reset reference potential that reverse biases the photodiode, and a control gate coupled to a source of a RESET signal. A photocharge integration node is coupled to said second terminal of said barrier transistor. The photocharge integration node comprises the control gate of a first source-follower transistor. The first source-follower transistor is coupled to a source of bias current and has an output. A capacitive storage node is coupled to the output of the first source-follower transistor and comprises the control gate of a second source-follower transistor having an output. An exposure transistor is coupled between the output of the first source-follower transistor and a global current-summing node and has a control gate coupled to a saturation level voltage.

HIGH-SENSITIVITY STORAGE PIXEL SENSOR HAVING AUTO-EXPOSURE DETECTION

BACKGROUND OF THE INVENTION

1. Field of the Invention

The present invention relates to digital cameras employing solid-state pixel sensors. More particularly, the present invention relates to improved sensitivity and autoexposure detection apparatus and methods for use in digital cameras.

2. The Prior Art

Storage pixel sensors are known in the art. These devices sense photo-integrated charge stored on a capacitor. A limitation of these prior pixels storage sensors is the tradeoff that results from the desire for the capacitor to be small to achieve high sensitivity and the competing desire for the capacitor to be large to provide low noise and good storage time.

Prior art exposure control techniques known to the inventors that use the actual image sensors during the actual exposure interval are of two types. Some prior art techniques integrate the total photocurrent by a common back-side electrode (anode) of a group of photodiodes—i.e., they integrate the substrate current to get an average light reading on the whole array. Other prior art techniques use nondestructive readout to sample selected pixels during the exposure interval, looking for an indication that some pixels are reaching a full-scale exposure. Another prior-art technique senses a total overflow charge from the pixel sensors.

The first technique is tricky and difficult to implement, since the photocurrents are small and the substrate is large and noisy. In addition, it responds strictly to the average light level across the image plane rather than to those pixels that are reaching a full-scale charge accumulation. The second technique requires a sequential polling, so is limited to either a very slow operation or to sensing only a very small subset of the pixels. The second technique is therefore not good for detecting the exact time when a small percentage of pixels are reaching a full-scale exposure. The third technique requires sensing of charges against a background of the total leakage of the full area of pixel sensors.

Other prior art techniques for exposure control typically measure the light either at a different time, e.g. just before the actual exposure, or with a different sensor device that needs to be calibrated relative to the sensor that is picking up the actual image. Such techniques typically sample the image plane at selected fixed points rather than adapting to the lighting conditions of the entire image.

One such prior art technique uses an imager first to estimate a light level and thereby to calculate an optimum exposure duration for a second cycle of the imager. This technique is obviously not as fast, and particularly is unsuited to controlling the exposure time rapidly during a dynamic lighting event, provided for example from a strobe flash.

Another such prior art technique employs a separate overall light sensor to measure an average light level and to react to a sufficient quantity of light by closing a shutter or quenching a strobe flash. Mechanical shutters and non-frame-storage electronic sensors cannot be shuttered rapidly enough to use this technique during a flash, which is why the detector is sometimes used to turn off the light source instead of closing a shutter. These techniques require an awkward coordination between the camera, the light sensor, and the

light source, and do not necessarily track automatically the sensitivity (or film speed) and lens aperture of the camera.

Another type of prior art technique relates to use of an adjustable overflow drain for dynamic range enhancement. These techniques have not been integrated with the use of the overflow current for terminating the exposure time. Variations on this technique employ either a moving overflow barrier or a dual exposure interval to increase dynamic range.

BRIEF DESCRIPTION OF THE INVENTION

According to a first aspect of the present invention, a MOS active storage pixel sensor disposed on a semiconductor substrate comprises a photodiode having a first terminal coupled to a first potential (ground) and a second terminal. A barrier transistor has a first terminal coupled to the second terminal of the photodiode and a second terminal coupled to a photocharge integration node comprising the control element of a first source-follower transistor. A semiconductor reset switch has a first terminal coupled to the second terminal of the barrier transistor and a second terminal coupled to a reset reference potential that reverse biases the photodiode. The first source-follower transistor is coupled to a bias current source and has an output. A bias transistor has its drain coupled to the output of the first source-follower transistor, its gate coupled to a fixed potential to establish the saturation level along with the fixed voltage on the gate of the saturation level transistor and a source coupled to a fixed voltage such as ground. A semiconductor transfer transistor has a first terminal coupled to the output of the first source-follower transistor and a second terminal connected to a capacitive storage node comprising the control element of a second source-follower transistor having an output. A row-select transistor has a first terminal coupled to the output of the second source-follower transistor, a second main terminal coupled to a column output line and a control element coupled to a row-select line. The reset transistor and the transfer transistor each have a control element coupled to a control circuit for selectively activating the reset transistor and the transfer transistor.

The separation of the photodiode from the charge integration node by the barrier transistor allows high sensitivity, and the separation of the storage node from the charge integration node by the first source-follower transistor allows low noise storage and readout by providing a smaller capacitance for the charge integration node and a larger capacitance for the storage node.

According to a second aspect of the present invention an auto-exposure circuit for use with pixel sensors is disclosed. A saturation level transistor has its source coupled to the output of the first source-follower amplifier, its gate coupled to a fixed potential chosen to turn the transistor on at a preselected pixel voltage representing a saturation level, and a common (global) current summing drain node. A bias transistor has its drain coupled to the output of the first source-follower amplifier, its gate coupled to a fixed potential to establish the saturation current and a source coupled to a fixed voltage such as ground. The global current summing node is coupled to a current comparator to compare the current flowing from the common drain node with a reference current. When the current from the global drain node exceeds the reference current, indicating that a preselected number of pixels in the array have saturated, the output of the comparator produces a TERMINATE EXPOSURE signal.

BRIEF DESCRIPTION OF THE DRAWING FIGURES

FIG. 1 is a schematic diagram of an illustrative MOS active pixel sensor incorporating an auto-exposure sensing circuit according to the present invention.

FIGS. 2A and 2B are timing diagrams that illustrate the operation of the pixel sensor of FIG. 1.

FIG. 3 is a block diagram of an illustrative array of MOS active pixel sensors and auto-exposure apparatus according to the present invention.

FIG. 4 is a diagram of an electronic camera including an array of pixel sensors and auto-exposure apparatus according to the present invention.

DETAILED DESCRIPTION OF A PREFERRED EMBODIMENT

Persons of ordinary skill in the art will realize that the following description of the present invention is illustrative only and not in any way limiting. Other embodiments of the invention will readily suggest themselves to such skilled persons having the benefit of this disclosure. For example, the illustrative embodiments of the present invention are disclosed using all N-Channel MOS transistor switches, but persons of ordinary skill in the art will appreciate that other technologies could be employed as well. Such skilled persons will readily understand how to adjust the polarities of the various potentials applied to the circuits disclosed herein to implement an embodiment of the present invention employing such other technologies.

The present invention encompasses various combinations of elements in storage pixel sensors. Different embodiments of storage pixel sensors according the present invention include one or more of the following elements in combination incorporated into the pixel sensor: a barrier transistor, a bias transistor for the source-follower transistor, a saturation level transistor, and a transfer transistor. The present invention is disclosed herein with reference to FIG. 1 as an embodiment including all of these elements in combination with disclosure of how each element functions in the combination, but persons of ordinary skill in the art will appreciate that multiple embodiments of the invention are contemplated having one or more of these elements in combination in a storage pixel sensor.

Referring first to FIG. 1, a schematic diagram of an illustrative high-sensitivity pixel sensor 10 incorporating an auto-exposure control according to the present invention is presented. Photodiode 12 has its anode coupled to a source of fixed potential (shown as ground) and a cathode. The cathode of photodiode 12 is coupled to the source of MOS N-Channel barrier transistor 14. The gate of MOS N-Channel barrier transistor 14 is coupled to a BARRIER line upon which a BARRIER control potential may be placed. Persons of ordinary skill in the art will appreciate that the use of MOS N-Channel barrier transistor 14 is optional in storage pixel sensor 10 of the present invention, at the cost of some sensitivity. Independent of the other transistors in the circuit, a barrier transistor 14 can be added to increase the sensitivity (the charge-to-voltage conversion gain) in darker areas of the image. The MOS N-Channel barrier transistor 14 allows essentially all of the charge from the photodiode to charge the gate capacitance of the first source follower transistor 20, providing a high gain, until that gate voltage falls low enough to turn the barrier transistor 14 on more, after which the storage pixel sensor 10 operates in the lower-gain mode (for lighter areas) in which the charge is charging both the photodiode capacitance and the gate capacitance.

The cathode of photodiode 12 is coupled to a photocharge integration node 16 (represented in FIG. 1 as a dashed line capacitor) through the MOS N-Channel barrier transistor 14. A MOS N-Channel reset transistor 18 has its source coupled

to the photocharge integration node 16, its gate coupled to a RESET line upon which a RESET signal may be asserted, and its drain coupled to a reset potential VR.

The photocharge integration node 16 comprises the inherent gate capacitance of first MOS N-Channel source-follower transistor 20, having a drain connected to a voltage potential VSFD1. The voltage potential VSFD1 may be held fixed at a supply voltage V+ (which may be, for example, about 3–5 volts depending on the technology) or may be pulsed as will be disclosed further herein. The source of MOS N-Channel source-follower transistor 20 forms the output node 22 of the source-follower transistor and is coupled to the drain of MOS N-Channel bias transistor 24 operating as a current source. The source of MOS N-Channel bias transistor 24 is coupled to a fixed voltage potential such as ground. The gate of MOS N-Channel source-follower bias transistor 24 is connected to a bias voltage node. The voltage presented to the bias voltage node sets the bias current flowing through MOS N-Channel source-follower bias transistor 24. This voltage may be fixed, or, as will be disclosed further herein, may be pulsed to conserve power. The use of MOS N-Channel source-follower bias transistor 24 is optional in the present invention. As will be disclosed herein, this device is used in combination with a saturation level transistor to implement an auto-exposure detection function.

The output node 22 of the source-follower transistor is coupled to a capacitive storage node 26 (represented in FIG. 1 as a dashed line capacitor). In some embodiments of the present invention, the output node 22 of the source-follower transistor is coupled to the capacitive storage node 26 through a MOS N-Channel transfer transistor 28. The gate of MOS N-Channel transfer transistor 28 is coupled to a XFR line upon which a XFR signal may be asserted. MOS N-Channel transfer transistor 28 is an optional element in the storage pixel sensor of the present invention.

The capacitive storage node 26 comprises the inherent gate capacitance of second MOS N-Channel source-follower transistor 30, having a drain connected to a source-follower drain (SFD) potential and a source. The source of second MOS N-Channel source-follower transistor 30 is coupled to COLUMN OUTPUT line 32 through MOS N-Channel row select transistor 34. The gate of MOS N-Channel row select transistor 34 is coupled to a ROW SELECT line 36.

Second MOS N-Channel source-follower transistor 30 is preferably a large device, having its gate sized at 10 to 100 times the area of first MOS N-Channel source-follower transistor 20. The other transistors in the circuit, first MOS N-Channel source-follower transistor 20, are preferably sized to near minimum length and width.

Use of a bias transistor 24 in the storage pixel sensor of the present invention can change the operating characteristics of the pixel sensor in a beneficial way. The first source-follower is working against a controlled current source, which may be more well controlled than when working against only the capacitive load of the storage node capacitance of the second source follower transistor 30.

To increase the input-to-output voltage gain of either source follower transistor 20 or 30, it is possible to pulse its drain terminal (as disclosed in FOV-013 for the readout follower). If the drain of the first source follower transistor 20 is pulsed, current will flow only when it is high, so the pixel saturation disclosed with reference to auto-exposure circuit 40 can be monitored only while it is high. It may be advantageous to pulse drain of the first source follower

5

transistor **20** with a low duty cycle to save power during exposure. Pulsing drain of the first source follower transistor **20** also keeps the photodiode and barrier source/drain voltages lower during the time the drain is low, which can beneficially reduce voltage-dependent leakage at those nodes. If the BARRIER and VR voltages are adjusted for proper barrier operation with the drain low, then the barrier transistor **14** will tend to turn off while the drain of the first source follower transistor **20** is pulsed, so the charge on the photodiode **12** will not be disturbed. The exposure needs to end with the drain high to capture the final state on the storage node.

Referring now to FIG. 2A, a timing diagram illustrates the operation of pixel sensor **10** of FIG. 1. Initially, the RESET signal is asserted high. The VR node at the drain of the MOS N-Channel reset transistor **18** is brought from zero volts to the voltage VR. This action resets all pixel sensors in the array by placing the voltage potential VR (less a threshold of the MOS N-Channel barrier transistor **14**) at the cathode of each photodiode **12**. According to a presently preferred method for operating the high-sensitivity pixel sensor of the present invention illustrated in FIG. 2A, the voltage VR is initially at a low level (e.g., to zero volts) while RESET is high to reset the cathode voltages of all photodiodes in the array to a low value to quickly equalize their states to prevent image lag. Then the voltage VR is raised (e.g., to about 2 volts) for a predetermined time (preferably on the order of a few milliseconds) while the RESET signal is still asserted to allow the photodiodes in all pixel sensors to charge up to about 1.4 volts through their associated MOS N-Channel barrier transistors **14**, whose gates are held at about 2 volts. The black level at the integration node is thus set to VR, less a little for the capacitive turn-off transient from the MOS N-Channel reset transistor, and the photodiodes are reset to their respective appropriate levels as determined by their respective barrier transistor thresholds. An advantage of this method is that those thresholds don't affect the black level that is read out. After reset ends and integration starts, some charge will still leak across the barrier by subthreshold conduction, but it should be about the same for all pixels, or at least be a monotonic function of light level.

According to a particularly advantageous operation of the storage pixels sensor of the present invention, the barrier transistor **14** and the reset transistor **18** are identically sized so as to exhibit identical voltage thresholds (V_{th}). The active level of the RESET signal is chosen such that $V_{RESET} < VR + V_{th}$, to achieve better tracking of nonlinearities.

When the RESET signal is de-asserted and photointegration begins, charge accumulates on the photocharge integration node **16**. Because MOS N-Channel barrier transistor **14** is barely conducting, photoinduced charge trickles across its channel and charges photocharge integration node **16** (by lowering its voltage) without lowering the voltage on the cathode of the photodiode **12**. This is advantageous because it minimizes the capacitance charged by the photocurrent, thereby maximizing the sensitivity (volts per photon).

Persons of ordinary skill in the art will appreciate that the MOS N-Channel reset transistor **18** can be coupled directly to the cathode of the photodiode **12**, but such an arrangement requires that the voltage VR be set precisely relative to the barrier voltage and threshold. This is not preferred since the thresholds can vary.

The voltage at the source of first MOS N-Channel source-follower transistor **20**, and hence its output node **22**, follows

6

the voltage on its gate (the photocharge integration node **16**). In embodiments of the present invention that employ MOS N-Channel transfer transistor **28**, the XFR signal is asserted throughout the reset period and the integration period and is de-asserted to end the integration period as illustrated in FIG. 2A. The low level of the XFR signal is preferably set to zero or a slightly negative voltage, such as about -0.2 volts, to thoroughly turn off transfer transistor **28**.

To read out a pixel sensor, the SFD node at the drain of the second MOS N-Channel source-follower transistor (labeled VSFD2 in FIG. 2A) is driven to the voltage VSFD, the ROW SELECT signal for the row of the array containing the pixel sensor **10** is asserted, and the output signal is thereby driven onto COLUMN OUTPUT line **32**. The timing of the assertion of the VSFD2 signal is not critical, except that it should remain high until after the ROW SELECT signal is de-asserted as illustrated in FIG. 2A. It may be advantageous to limit the voltage slope at the rising edge of the ROW SELECT signal if VSFD2 is raised first, as disclosed in co-pending application Ser. No. 09/492,103, filed Feb. 14, 2000, docket No. FOV-038.

Referring now to FIG. 2B, if the XFR transistor is not present, the storage node may be isolated by lowering SFBIAS (preferably to zero or a slightly negative voltage such as about -0.2 volts) and setting VR low, and then asserting the RESET signal. This sequence turns off the first source follower **20** by lowering the voltage on its gate while its load current is turned off, thereby storing its output voltage.

In FIG. 2B, the VR falling edge and the RESET rising edge are shown following closely on the terminate signal, since these transistors isolate the storage node to end the exposure. In FIG. 1A, the corresponding transitions are shown with more delay since they are not critical when XFR falling isolates the storage node. The SFBLAS signal needs to fall only in the case of FIG. 2B; when there is a transfer transistor the bias can be steady.

Also shown in FIG. 2B is the signal VSFD1 to illustrate an embodiment of the present invention in which VSFD1 is pulsed. As disclosed herein, the VSFD1 node may always be left high, or, as shown in FIG. 2B VSFD1 may be pulsed thus saving power. In embodiments of the present invention in which VSFD1 is pulsed, terminate will become true during a pulse. VSFD1 is held high until RESET goes high or, in embodiments employing a transfer transistor, until XFR goes low.

Second MOS N-Channel source-follower transistor **30** is larger than first MOS N-Channel source-follower transistor **20**, and its gate capacitance (the capacitive storage node **26**) is therefore correspondingly larger. This provides the advantage of additional noise immunity for the pixel sensor **10** because more charge needs to be transferred to or from the capacitive storage node **26** to cause a given voltage change than is the case with the photocharge integration node **16**.

The control signals depicted in FIGS. 2A and 2B may be generated using conventional timing and control logic. To this end, timing and control logic circuit **38** is shown in FIG. 1. The configuration of timing and control logic circuit **38** will depend on the particular embodiment of the present invention, but in any event will be conventional circuitry, the particular design of which is a trivial task for persons of ordinary skill in the art having examined FIGS. 2A and 2B once a particular embodiment of the present invention is selected.

Referring again to FIG. 1, an auto-exposure circuit **40** for use with pixel sensors according to a second aspect of the

present invention is disclosed. According to this aspect of the invention, each pixel in the array includes a MOS N-Channel saturation level transistor **42**, having its source coupled to the output node **22** of the first MOS N-Channel source-follower transistor **20**, its gate coupled to SAT. LEVEL line **44**, and its drain connected to a global current summing node **46**. Global current summing node **46** is coupled to a current comparator **48**. Persons of ordinary skill in the art will appreciate that current comparator **48** may comprise a diode load or a resistor coupled between a voltage source and global current summing node **46** driving one input of a voltage comparator. The other input of the voltage comparator would be coupled to a voltage representing a desired number of saturated pixels. Alternatively, an analog-to-digital converter may be used and the comparison may be done digitally.

A saturation level transistor **42** can be used, only if the bias transistor **24** is present, to divert the bias current from saturated pixel sensors onto a global current summing line that can be monitored during exposure to determine how many pixels have reached the saturation level. External circuits can control the threshold for what is deemed saturation, and can measure the current instead of just comparing it to a threshold, so it is possible through this added transistor and global current summing line to measure how many pixel sensors have crossed any particular level. Therefore, by performing rapid variation of the threshold (SAT. LEVEL) and rapid measurement (e.g. through an A/D converter and input to a processor), it is possible to have access to a complete cumulative histogram of exposure levels during the exposure; from this information, it is possible to make more complex determinations of good exposure levels, beyond the simple threshold method used in the presently preferred embodiment.

When the bias transistor **24** is present, isolating the storage node involves timing signals to turn off both the bias transistor **24** and the first source follower **20**. It is simpler, and potentially advantageous in terms of storage integrity, to include a transfer transistor **28** that can isolate the storage node under control of a single logic signal. The transfer transistor **28** can also be added to the basic circuit, even without the bias transistor, for a similar advantage, since even turning off the first source follower transistor **20** reliably involves coordinating the Reset and VR signals, which is a complexity that can be eliminated with the transfer transistor **28**.

In operation, the SAT. LEVEL line **44** is driven to a voltage VSAT corresponding to a selected photocharge saturation level. Because accumulation of photocharge drives the output node **22** of the first MOS N-Channel source-follower transistor **20** downward, MOS N-Channel saturation level transistor **42** is initially turned off because its gate voltage at VSAT is lower than the voltage at node **16**. MOS N-Channel saturation level transistor **42** remains off until accumulation of photocharge at photocharge integration node **16** has lowered its voltage below VSAT (and that at the source of MOS N-Channel saturation level transistor **42**, common to the output node **22** of the first MOS N-Channel source-follower transistor **20**, to a level one V_t below the voltage VSAT). At this point, MOS N-Channel saturation level transistor **42** turns on and starts to draw current (less than or equal to the bias current through bias transistor **24**) from the global current summing node **46**.

As will be appreciated by persons of ordinary skill in the art, other pixel sensors in the array will also begin to accumulate enough photocharge to turn on their MOS N-Channel saturation level transistors **42**, thus drawing

additional current from node **46**, and further dropping the voltage on global current summing node **46**. As will be appreciated by persons of ordinary skill in the art, comparator **48** may be a voltage comparator having one input coupled to global current summing node **46** and one input coupled to a voltage VTERM chosen to correspond to the voltage on global current summing node **46** when a selected number of pixels are saturating (i.e., have their MOS N-Channel saturation level transistors **42** turned on). When the voltage on global current summing node **46** equals VTERM, the comparator **48** generates a TERMINATE EXPOSURE signal that can be used to terminate the exposure period in one of numerous ways, such as by closing a mechanical shutter or initiating end-of-exposure signals (such as the XFR signal) to control the pixel sensors. The TERMINATE EXPOSURE signal can also be used to quench a strobe flash if desired.

Alternatively, A/D converter **50** may be coupled to global current summing line **46** to convert the voltage representing the global summed current to a digital value that can be processed by employing a smart auto-exposure algorithm shown at reference numeral **52**.

The auto-exposure circuit **40** of the present invention may be advantageously operated in a power saving mode by simultaneously pulsing both the VSFD1 signal to the drain of the source-follower transistor **20** and one or both of the SF bias signal supplied to the gate of source-follower bias transistor **24** and the SAT. LEVEL signal supplied to the gate of saturation level transistor **42**. In such a mode, the auto-exposure sensing current flows only when these signals are pulsed, at which time the overexposure sensing is performed. At other times during photointegration, the overexposure currents from each pixel do not flow, thus saving power. When this mode of operation is used, the auto-exposure circuit **40** can be advantageously used at higher current levels for better signal-to-noise ratio.

According to another mode of operating the auto-exposure circuit **40** of the present invention, the SAT. LEVEL voltage at the gates of all saturation level transistors **42** in an array can be swept from zero to the maximum level do develop a full cumulative distribution of the states of all pixels in the array. This mode of operation is most useful when AID converter **50** is used in the auto-exposure circuit **40**. In embodiments of the present invention employing optional transfer transistor **28**, this device should either be turned off before the ramping of SAT. LEVEL voltage each measurement cycle, or an extra cycle should be performed with the SAT. LEVEL voltage low in order to store a signal voltage that is not clipped to the variable SAT. LEVEL voltage. An example of an autoexposure algorithm that could use this cumulative distribution information is one that would analyze the distribution and classify the scenes as being backlit or not, and set different values of SAT. LEVEL and i-threshold accordingly, during exposure.

In a typical application of the MOS pixel sensor of the present invention, a plurality of such pixel sensors will be disposed in an array. Referring now to FIG. **3**, a block diagram shows an illustrative 2 by 2 portion of an array of pixel sensors and auto-exposure apparatus according to the present invention. Persons of ordinary skill in the art will readily appreciate that the array portion disclosed in FIG. **3** is illustrative only and that arrays of arbitrary size may be fabricated using the teachings herein.

As would be expected by persons of ordinary skill in the art and as shown in FIG. **3**, common RESET, BARRIER, SF BIAS, and SAT. LEVEL lines will be provided for all of the

pixel sensors in the array. As presently preferred, a separate VSFD line is provided for each row in the array, although embodiments of the present invention having a single VSFD node are also contemplated. The source of each N-Channel MOS row select transistor in FIG. 1 for each pixel sensor in a column of the array will be coupled to a column line associated with that column and the gate of the N-Channel MOS row select transistor in FIG. 1 for each pixel sensor in a row of the array will be coupled to a ROW SELECT line associated with that row.

The 2 by 2 portion 60 of the array in FIG. 3 includes two rows and two columns of MOS active pixel sensors according to the present invention. A first row includes MOS active pixel sensors 62-1 and 62-2; a second row includes MOS active pixel sensors 62-3 and 62-4. A first column includes MOS active pixel sensors 62-1, 62-3; a second column includes MOS active pixel sensors 62-2 and 62-4.

A first ROW SELECT line 64-1 is connected to the row-select inputs (RSEL) of MOS active pixel sensors 62-1 and 62-2. A second ROW SELECT line 64-2 is connected to the row-select inputs (RSEL) of MOS active pixel sensors 62-3 and 62-4. The first and second ROW SELECT lines may be driven from a row decoder (not shown) as is well known in the art.

A first COLUMN OUTPUT line 66-1 is connected to the outputs (OUT) of MOS active pixel sensors 62-1 and 62-3. A second COLUMN OUTPUT line 66-2 is connected to the outputs (OUT) of MOS active pixel sensors 62-2 and 62-4. The first and second COLUMN OUTPUT lines are coupled to a column readout circuit (not shown) as is well known in the art.

A global RESET line 68 is connected to the reset (R) inputs of all of the MOS active pixel sensors 62-1 through 62-4. A first VSFD line 70-1 is connected to the VSFD inputs of the MOS active pixel sensors 62-1 and 62-2 in the first row of the array. A second VSFD line 70-2 is connected to the VSFD inputs of the MOS active pixel sensors 62-3 and 62-4 in the second row of the array. A global BARRIER line 72 is connected to the BARRIER inputs of all of the MOS active pixel sensors 62-1 through 62-4. A global SAT LEVEL line 74 is connected to the SAT LEVEL inputs of all of the MOS active pixel sensors 62-1 through 62-4. A global XFR line 78 is connected to the XFR inputs of all of the MOS active pixel sensors 62-1 through 62-4.

Auto-exposure circuit 80 is coupled to the GLOBAL CURRENT SUMMING LINE line 82 and generates a TERMINATE EXPOSURE signal on line 84 as described herein. The TERMINATE EXPOSURE signal on line 84 may be used to terminate the exposure of the image in a known manner, e.g., by closing a mechanical shutter, or electronically by causing the transition of the signals in FIG. 2 that isolate the storage node and/or quench a strobe flash.

When the array including 2 by 2 portion 60 is driven by the signals shown in FIG. 2, images may be captured. One particular application of such an array is in a digital camera.

Referring now to FIG. 4, a block diagram of an illustrative digital camera 90 employing an array of MOS active pixel sensors and auto-exposure control according to the present invention is presented in schematic form. A color-separating prism 92 is shown mounted inside light-tight housing 94. Lens 96 is fitted to the housing in such a manner that it projects through the input face 98 of the prism 92, an image which is thereby split into red, green, and blue images, which are each focussed on one of output faces 100, 102, and 104 of prism 82.

Attached to the three output faces of prism 92 are three chip-on-board assemblies, labeled 106R, 106G, and 106B,

aligned in such a way that the color-separated images fall on their active areas in registration. Each chip-on-board assembly includes an imaging array of pixel sensors like that partially depicted in FIG. 3 according to the present invention. Each of these arrays is attached to its respective prism face. One method for attaching these arrays to the prism faces is disclosed in co-pending application Ser. No. 09/302,565, filed Apr. 30, 1999, expressly incorporated herein by reference.

Signal connections to the chip-on-board assemblies 106R, 106G, and 106B are made by way of a ribbon cable 108 which is fitted with three connectors that mate with connectors on the 3 chip-on-board assemblies. In addition, ribbon cable 98 is attached to a circuit board 110 by way of connector 112. Circuit board 110 comprises the support electronics for controlling the reading of image data from the three imaging arrays on the chip-on-board assemblies 106R, 106G, and 106B mounted on the prism 92 as is understood by those skilled in the art. Cable 114 carries power into camera 80, and carries out of the camera signals representative of the image captured through lens 86. Cable 114 exits housing 94 through light-tight fixture 116.

While embodiments and applications of this invention have been shown and described, it would be apparent to those skilled in the art that many more modifications than mentioned above are possible without departing from the inventive concepts herein. The invention, therefore, is not to be restricted except in the spirit of the appended claims.

What is claimed is:

1. A plurality of storage pixel sensors disposed on a semiconductor substrate, each of the plurality of storage pixel sensors comprising:

a photodiode having a first terminal coupled to a first potential and a second terminal;

a reset transistor having a first terminal coupled to the second terminal of the photodiode, a second terminal coupled to a reset reference potential that reverse biases the photodiode, and a control gate coupled to a RESET signal node;

a photocharge integration node coupled to said first terminal of said reset transistor, said photocharge integration node comprising the control gate of a source-follower transistor, said source-follower transistor having a drain, coupled to a source-follower drain supply voltage node, and a source coupled to means for generating a bias current;

a capacitive storage node, coupled to the source of the source-follower transistor, comprising the input of a readout amplifier transistor having an output; and

an exposure transistor having a source directly connected to the source of said source-follower transistor and a drain coupled to a global current-summing node, said exposure transistor having a control gate coupled to a saturation level control voltage, said exposure transistor and said source-follower transistor acting as a common-source differential pair to divide said bias current between said source-follower transistor and said exposure transistor according to the relative values of integrated photosignal on said control gate of said source-follower transistor and said saturation level control voltage on said gate of said exposure transistor.

2. Each of the plurality of storage pixel sensors of claim 1 including means for selectively pulsing said source-follower drain supply voltage node.

3. Each of the plurality of storage pixel sensors of claim 1 wherein said readout amplifier is a second source-follower

11

transistor having a drain coupled to a second source-follower drain supply voltage node and said capacitive storage node is a gate associated therewith.

4. Each of the plurality of storage pixel sensors of claim 3 further coupled to means for selectively pulsing said second source-follower drain supply voltage.

5. Each of the plurality of storage pixel sensors of claim 1 wherein said means for generating a bias current comprises a bias transistor having a source coupled to a fixed voltage source, a gate coupled to a bias voltage node and a drain coupled to the source of said source-follower transistor.

6. Each of the plurality of storage pixel sensors of claim 5 wherein the gate of said bias transistor is coupled to a bias voltage node that may be selectively pulsed.

7. Each of the plurality of storage pixel sensors of claim 1 further including a barrier transistor having first and second terminals coupled between the second terminal of the photodiode and said first terminal of said reset transistor, said barrier transistor having a control terminal coupled to a barrier set voltage.

8. Each of the plurality of storage pixel sensors of claim 7 wherein said reset transistor and said barrier transistor are sized so as to have substantially matched voltage thresholds.

9. Each of the plurality of storage pixel sensors of claim 1 further comprising a transfer transistor disposed between said source of said source-follower transistor and the capacitive storage node, said transfer transistor having a first terminal coupled to said source of said source-follower transistor, a second terminal coupled to the capacitive storage node and a control gate coupled to a XFR signal node.

10. Each of the plurality of storage pixel sensors of claim 9 further comprising:

a row-select transistor having a first terminal coupled to the output of the readout amplifier, a second terminal coupled to a column output line and a control gate coupled to a ROW SELECT signal node; and

a control circuit for selectively activating a RESET signal on said RESET signal node, a XFR signal on said XFR signal node, and a ROW SELECT signal on said ROW SELECT signal node.

11. A plurality of storage pixel sensors disposed on a semiconductor substrate, each of the plurality of storage pixel sensors comprising:

a photodiode having a first terminal coupled to a first potential and a second terminal;

a barrier transistor having a first terminal coupled to the second terminal of the photodiode, said barrier transistor having a second terminal and a control gate coupled to a barrier set voltage;

a reset transistor having a first terminal coupled to the second terminal of the barrier transistor, a second terminal coupled to a reset reference potential that reverse biases the photodiode, and a control gate coupled to a RESET signal node;

a photocharge integration node coupled to said second terminal of said barrier transistor, said photocharge integration node comprising the control gate of a source-follower transistor, said source-follower transistor having a drain, coupled to a source-follower drain supply voltage node, and a source;

a capacitive storage node, coupled to said source of said source-follower transistor, comprising the input of a readout amplifier transistor having an output; and

an exposure transistor having a source directly connected to the source of said source-follower transistor and a

12

drain coupled to a global current-summing node, said exposure transistor having a control gate coupled to a saturation level control voltage, said exposure transistor and said source-follower transistor acting as a common-source differential pair to divide said bias current between said source-follower transistor and said exposure transistor according to the relative values of integrated photosignal on said control gate of said source-follower transistor and said saturation level control voltage on said gate of said exposure transistor.

12. Each of the plurality of storage pixel sensors of claim 11 including means for selectively pulsing said source-follower drain supply voltage node.

13. Each of the plurality of storage pixel sensors of claim 11 wherein said readout amplifier is a second source-follower transistor having a drain coupled to a second source-follower drain supply voltage node and said capacitive storage node is a gate associated therewith.

14. Each of the plurality of storage pixel sensors of claim 13 further coupled to means for selectively pulsing said second source-follower drain supply voltage.

15. Each of the plurality of storage pixel sensors of claim 11 wherein said means for generating a bias current comprises a bias transistor having a source coupled to a fixed voltage source, a gate coupled to a bias voltage node and a drain coupled to the source of said source-follower transistor.

16. Each of the plurality of storage pixel sensors of claim 15 wherein the gate of said bias transistor is coupled to a bias voltage node that may be selectively pulsed.

17. Each of the plurality of storage pixel sensors of claim 11 wherein said reset transistor and said barrier transistor are sized so as to have substantially matched voltage thresholds.

18. Each of the plurality of storage pixel sensors of claim 11 further comprising a transfer transistor disposed between said source of said source-follower transistor and the capacitive storage node, said transfer transistor having a first terminal coupled to said source of said source-follower transistor, a second terminal coupled to the capacitive storage node and a control gate coupled to a XFR signal node.

19. Each of the plurality of storage pixel sensors of claim 11 further comprising a row-select transistor having a first terminal coupled to the output of the readout amplifier, a second terminal coupled to a column output line and a control gate coupled to a ROW SELECT signal node, and

a control circuit for selectively activating a RESET signal on said RESET signal node, a XFR signal on said XFR signal node, and a ROW SELECT signal on said ROW SELECT signal node.

20. A pixel sensor disposed on a semiconductor substrate comprising:

a photodiode having a first terminal coupled to a first potential and a second terminal;

a reset transistor having a first terminal coupled to the second terminal of the photodiode, a second terminal coupled to a reset reference potential that reverse biases the photodiode, and a control gate coupled to a RESET signal node;

a photocharge integration node coupled to said first terminal of said reset transistor, said photocharge integration node comprising the control gate of a source-follower transistor, said source-follower transistor having a drain coupled to a source-follower drain supply voltage node and a source coupled to means for generating a bias current; and

an exposure transistor having a source directly connected to said output of said source-follower transistor and

13

drain directly connected to a global current-summing node, said exposure transistor having a control gate coupled to a saturation level control voltage, said exposure transistor and said source-follower transistor acting as a common-source differential pair to divide 5 said bias current between said source-follower transistor and said exposure transistor according to the relative values of integrated photosignal on said control gate of said source-follower transistor and said saturation level control voltage on said gate of said exposure 10 transistor.

21. The pixel sensor of claim 20 further coupled to means for selectively pulsing said source-follower drain supply voltage node.

22. The pixel sensor of claim 20 wherein said means for 15 generating a bias current comprises a bias transistor having a source coupled to a fixed voltage source, a gate coupled to a bias voltage node and a drain coupled to the source of said source-follower transistor.

23. The pixel sensor of claim 22 wherein the gate of said 20 bias transistor is coupled to a bias voltage node that may be selectively pulsed.

24. The pixel sensor of claim 20 further including a barrier transistor having first and second terminals coupled between 25 the second terminal of the photodiode and said first terminal of said reset transistor, said barrier transistor having a control terminal coupled to a barrier set voltage.

25. The pixel sensor of claim 24 wherein said reset transistor and said barrier transistor are sized so as to have 30 substantially matched voltage thresholds.

26. The pixel sensor of claim 20, further including a capacitive storage node, coupled to said source of said

14

source-follower transistor, comprising the input of a readout amplifier transistor having an output.

27. The storage pixel sensor of claim 26 wherein said readout amplifier is a second source-follower transistor having a drain coupled to a second source-follower drain supply voltage node and said capacitive storage node is a gate associated therewith.

28. The storage pixel sensor of claim 27 further including means for selectively pulsing said second source-follower drain supply voltage.

29. The storage pixel sensor of claim 27 further comprising a transfer transistor disposed between the output of the source-follower transistor and the capacitive storage node, said transfer transistor having a first terminal coupled to the output of the source-follower transistor, a second terminal coupled to the capacitive storage node and a control gate coupled to a XFR signal node.

30. The storage pixel sensor of claim 29 further comprising:

a row-select transistor having a first terminal coupled to the output of the readout amplifier, a second terminal coupled to a column output line and a control gate coupled to a ROW SELECT signal node; and

a control circuit for selectively activating a RESET signal on said RESET signal node, a XFR signal on said XFR signal node, and a ROW SELECT signal on said ROW SELECT signal node.
