(57) **ABSTRACT**

A surface cleaning apparatus comprises a body including a rear compartment, a forward compartment and an intermediate compartment arranged between the rear and forward compartments. An elongate rotatable brush arrangement is positioned within and extends across the forward compartment. An electric motor is positioned in the rear compartment for driving the rotatable brush arrangement and the electric motor.

**SURFACE CLEANING APPARATUS****FIELD OF THE INVENTION**

This invention relates to a surface cleaning apparatus, such as for a floor or upholstery, incorporating an elongate rotatable brush arrangement and an electric motor for rotating the brush.

**BACKGROUND OF THE INVENTION**

Current surface cleaning devices conventionally employ suction means. One of the drawbacks of such suction means is that the fans used to generate suction are relatively inefficient, i.e. typically 10 to 12 percent efficient in use, with the result that such apparatus tends not to be easily portable. This is especially the case where the apparatus incorporates batteries for powering the motor. It is therefore not practical to incorporate batteries of sufficient power in a readily portable suction cleaner in order to provide the degree of suction required for effective cleaning.

It is conventional to provide a surface cleaning apparatus, such as for sweeping, in which an elongate brush arrangement, sometimes known as a brush bar, is supported for rotation in a housing which is adapted to be propelled at least in a forwards direction. The brush arrangement generally extends transversely of the housing and is adapted to contact a surface beneath it. The brush arrangement is arranged to be rotated by friction resulting from propelling the housing across a floor. The housing can be provided with wheels which contact the surface. One of the drawbacks of such a construction is that the friction drive is not very effective.

It is also conventional to provide one or more auxiliary brush arrangements extending outwardly from one or two front corners of the housing. The auxiliary brush arrangement is provided for rotation about an axis inclined to the vertical and is provided with radial bristles. An auxiliary brush arrangement of this kind is described in GB-A-1 547 286. The auxiliary brush arrangement is freely rotatable and relies for its rotation on contact with the floor or a skirting board of a room during propulsion of the apparatus across the floor. Such means of rotation is unreliable and results in particles of dust and/or dirt on the floor being flicked towards the elongate rotating brush assembly for collection by the apparatus. Furthermore, contact of the circular auxiliary brush arrangement with the floor or a skirting board results in bristles of the auxiliary brush arrangement which extend outwardly sideways from the housing undergoing angular rotation effectively in a backwards direction. This means that an auxiliary brush means extending outwardly from a front right hand corner of the housing, as viewed from above and behind the apparatus, would be rotated in a clockwise direction and would flick dust and or dirt around behind it in the direction of the elongate rotating brush arrangement. This is not very satisfactory.

In current vacuum cleaner attachments, it is conventional to employ a flexible cleaning strip intended for cleaning hard floor surfaces, for example tiles, marble or linoleum. The flexible strip is intended to increase air speed and mechanically gather particles to assist performance. On a forward stroke the flexible strip will push particles forward. When the vacuum cleaner attachment is pulled in a rearward direction, the gathered particles are left behind by the strip and are extracted by the suction. A disadvantage is that the flexible strip can gather particles on the rearward side, away from the suction, when the attachment is pulled in a rearward direction. However, the action of the suction itself

causes the majority of the particles on the rearward side of the flexible strip to pass under the flexible strip and be removed.

Conventional flexible cleaning strips used to clean hard floor surfaces can wear out relatively quickly due to the constant contact with the hard floor surface when in use. Flexible strips used on devices, for example, for washing hard floor surfaces are known to wear out relatively quickly without the benefit of a lubricating cleaning solution which reduces friction between the flexible strip and the floor.

**SUMMARY OF THE INVENTION**

It is therefore an object of the present invention to provide a surface cleaning apparatus which overcomes, or at least ameliorates, at least some of the problems of known apparatus.

In an embodiment, the invention provides a surface cleaning apparatus, comprising a body having a forward compartment and rear compartment; an elongate rotatable brush extending across the forward compartment; an electric motor in the rear compartment; a belt connecting the motor and rotatable brush; and a handle movable between an upright position and steering positions by rotation about an axis transverse to the axial direction of the handle, said handle being further rotatable around a second axis in said steering positions, wherein said second axis of rotation is offset from the axial direction of the handle.

In another embodiment, the invention comprises a surface cleaning apparatus, comprising a body having a forward compartment and rear compartment; an elongate rotatable brush extending across the forward compartment; an electric motor in the rear compartment; a belt connecting the motor and rotatable brush; and an intermediate compartment comprising a removable tray, wherein at least one side of the removable tray forms a wall of said body.

In other embodiments, the invention further comprises an auxiliary brush extending from the forward compartment. The auxiliary brush can be driven by the electric motor used to drive the elongate rotatable brush, such as by connecting the auxiliary brush to the elongate rotatable brush with a gear drive. In still other embodiments, the invention can comprise a body with a removable side wall to allow access to the intermediate compartment. The removable side wall can also include a cover. Alternatively, the entire intermediate compartment can be a removable tray. The walls of the removable tray can form one or more walls of the body of the apparatus. In an embodiment, the belt connecting the motor to the elongate rotatable brush passes through the intermediate compartment, preferably on the side of the compartment remote from a removable side wall.

In yet other embodiments, the wall between the forward and intermediate compartments can be inclined rearwardly, such as at an angle of about 15° to about 20°. The forward compartment can also have a movable portion to expose the bristles of the elongate rotatable brush. The wall between the rear and intermediate compartments can seal the rear compartment off from the intermediate compartment. The rear compartment can also be provided with ground-engaging wheels.

**BRIEF DESCRIPTION OF THE DRAWINGS**

For a better understanding of the present invention and to show more clearly how it may be carried into effect reference will now be made, by way of example, to the accompanying drawings in which:

3

FIG. 1 is a plan view of one embodiment of a surface cleaning apparatus according to the present invention;

FIG. 2 is a side elevational view, partly in section, of the surface cleaning apparatus shown in FIG. 1;

FIG. 3 is an elevational view of the surface cleaning apparatus of FIGS. 1 and 2 with an alternative handle;

FIG. 4 is a perspective view of another embodiment of a surface cleaning apparatus according to the present invention with part of a brush bar cover removed for illustrative clarity;

FIG. 5 is a perspective view of the apparatus of FIG. 4, with part of the housing thereof removed;

FIG. 6 is an underside view of the apparatus of FIG. 4 with part of the brush bar cover removed for clarity;

FIG. 7 is a perspective view of an alternative embodiment of surface cleaning apparatus according to the present invention with part of the brush bar cover removed for clarity (shown in dashed lines);

FIG. 8 is a perspective view of a further embodiment of a surface cleaning apparatus according to the present invention with part of the brush bar cover removed for clarity (shown in dashed lines);

FIG. 9 depicts an embodiment of the surface cleaning apparatus with a removable tray;

FIG. 10 is a perspective view of an embodiment of a surface cleaning apparatus with the handle in an upright position;

FIG. 11 is a perspective view of a surface cleaning apparatus with the handle in a lowered position;

FIG. 12 depicts rotation of the handle in an embodiment of the surface cleaning apparatus;

FIG. 13 is a perspective view of a cleaning strip assembly for use in a surface cleaning apparatus according to the invention;

FIG. 14 is a perspective view of another cleaning strip assembly for use in a surface cleaning apparatus according to the invention;

FIG. 15 is a perspective view of the cleaning strip in a first and a second orientation;

FIG. 16 is a side elevational view of an alternative embodiment of a cleaning strip assembly in a lowered and raised position, showing the relationship between the cleaning strip and a separate friction means;

FIG. 17 is side elevational view of a further embodiment of a cleaning strip assembly in a lowered position; and

FIG. 18 is a side elevational view of the cleaning strip assembly of FIG. 16 showing an alternative form of friction means.

#### DETAILED DESCRIPTION OF THE INVENTION

The surface cleaning apparatus shown in FIGS. 1 and 2 comprises a body 1, suitably moulded of one or more plastic materials, and having effectively three compartments.

A rear compartment 3 houses an electric motor 5 and a rechargeable battery pack 7. The battery pack 7 may be connected to a main power supply (not shown) for recharging the battery pack. The battery pack may either be connected to the main supply whenever the apparatus is not in use or at suitable times when the battery pack has become depleted. Switch means (not shown) is provided to permit a user to energise and de-energise the motor 5 as desired. As an alternative to a rechargeable battery pack, the apparatus could employ disposable batteries or be main powered (i.e., adapted to use standard household alternating current).

4

A forward compartment 9 houses an elongate rotatable brush arrangement 11. For convenience a forward wall of the forward compartment is arcuate and extends around the periphery of the brush arrangement 11. The bottom of the forward compartment is open at 13 to allow the bristles of the brush arrangement to contact a floor, carpet or the like over which the surface cleaning apparatus is to be moved. The rear of the forward compartment is a rearwardly inclined wall 15 which allows debris, such as dust, dirt and the like, to be propelled up the wall due to rotation of the brush arrangement 11 and to pass over the wall into an intermediate compartment 17 which will be described in more detail hereinafter. The wall 15 extends upwardly to about the same height as the top of the brush arrangement 11 and is angled rearwardly (i.e. away from the forward compartment) at an angle of about 18 degrees. The precise angle is not important, but the inclination facilitates the passage of the debris up and over the wall and at the same time facilitates retention of the debris within the intermediate compartment 17. The brush arrangement extends substantially the entire width of the forward compartment and is provided with two helically arranged rows of bristles. The two rows are diametrically opposed and each row is in the form of a pair of separate helices which twist in opposite directions and meet substantially midway between the ends of the brush arrangement.

The intermediate compartment 17 is positioned between the wall 15 and a wall 21 which encloses the electrical components 5, 7 in the rear compartment 3, the wall 21 protecting the components in the rear compartment from the ingress of debris. The intermediate compartment 17 also has a lower wall or bottom, an upper wall or top, and side walls formed by the outer wall of the body 1. Debris therefore accumulates within the intermediate compartment 17. The intermediate compartment is provided with a removable closure to facilitate the removal of debris. For example, one of the walls, such as a side wall, the upper wall or the lower wall, can be removed in order that the debris can be emptied from the intermediate compartment, the removed wall being replaced once the compartment has been emptied. Ideally, side wall 23 is removable for emptying purposes. The wall 15 provides the advantage that debris does not readily escape from the intermediate compartment 17 and, even if the body is inclined such that the forward compartment is below the intermediate compartment, the debris does not escape from the intermediate compartment.

In another embodiment, intermediate compartment 17 is a removable tray as shown in FIG. 9. In such an embodiment, side wall 23 can be separately removable from the intermediate compartment 17, or a side wall 73 and intermediate compartment 17 can be part of a single component as shown in FIG. 9. Intermediate compartment 17 can also incorporate additional structural portions of body 1, such as a portion 83 of the top wall of body 1. The top wall portion 83 and side wall 73 (or separately removable side wall 23) can be made of a transparent plastic material to allow for visual inspection of the amount of dirt collected in intermediate compartment 17. The bottom of removable tray 17 can serve as part of the bottom wall of body 1, or body 1 can have a separate bottom wall that tray 17 rests on when inserted into body 1.

In an embodiment, the removable tray serving as intermediate compartment 17 is separated from forward compartment 9 by at least one wall 85 formed by a side of intermediate compartment 17. A separate wall 15 (see FIG. 2) that is not attached to intermediate compartment 17 can also be present. Similarly, intermediate compartment 17 is

separated from rear compartment **3** by a wall **87** that is integral to the intermediate compartment **17** and/or a separate wall **21**.

Returning to FIGS. **1** and **2**, in an embodiment the brush arrangement **11** is rotated by motor **5**, such as by way of toothed rollers **25**, **27** attached to the motor and to the brush, respectively, and by way of a toothed belt **29**, for example of elastomeric material, extending around the two rollers. The toothed belt **29** is enclosed within a tunnel **31** where it passes through the intermediate compartment **17** in order to prevent the ingress of debris into the rear compartment **3**. The tunnel **31** may pass through the intermediate compartment **17** at any convenient point. However, particularly in the event side wall **23** and/or intermediate compartment **17** is removable for emptying purposes, the tunnel may be arranged at that side of the intermediate compartment **17** remote from the side wall **23**.

A handle **33** is attached to the body **1** in the region of the rear compartment **3**, the body being formed with a recess **35** beneath the handle to allow the handle to be gripped while maintaining a low profile for the surface cleaning apparatus. The handle **33** may be in two parts, a first part **37** which is secured to the body **1** and a second part **39** which can be removed from the first part and replaced by a longer handle part **41** as shown in FIG. **3**. The longer handle part **41** is provided with swivel means **43** to allow the handle part **41** to rotate about the axis thereof relative to the body **1** and with pivot means **45** to allow the handle part to pivot about an axis transverse to the axial direction of the handle part to enable the surface cleaning apparatus to be steered by the user. As an alternative to interchangeable handles, the handle part **41** may be removably engageable with the handle part **33**. In such a case, the handle part **33** is arranged such that the swivel means **43** functions only in certain positions of the handle part **33** in order that movement can be inhibited when the handle part **33** is used alone.

FIGS. **10–12** depict another embodiment for connecting a handle **33** to body **1**. FIG. **10** shows handle **33** in an upright position. From this upright position, handle **33** can be rotated around an axis transverse to the axial direction of the handle.

Rotating handle **33** around the axis transverse to the axial direction of the handle places the handle in a sweeping position, such as that shown in FIG. **11**. Sweeping positions can be discrete positions along the axis of rotation, but preferably handle **33** will be able to smoothly rotate to any position along the arc of rotation. The term “sweeping position” will be used to refer to any position within this continuous arc other than upright positions.

FIG. **11** shows a handle **33** pivotably attached to body **1** at attachment joint **230**. In a sweeping position, handle **33** can be pivoted around attachment joint **230**. In the embodiment shown in FIG. **11**, the axial direction of handle **33** does not coincide with the pivot axis at attachment joint **230**. As a result, handle **33** may be rotated around attachment joint **230**, but the axis of rotation does not coincide with the axial direction of the handle. Instead, rotation around attachment joint **230** causes handle **33** to rotate into an offset position, as shown in FIGS. **12a–c**. FIG. **12a** shows a handle rotated to the left around attachment joint **230**, while FIG. **12c** shows a handle rotated to the right. Handle **33** is offset from its original axis in both FIGS. **12a** and **12c**. The offset created by rotating handle **33** around attachment joint **230** allows for ease of movement of the sweeper when attempting to move the sweeper around a corner or obstacle.

If handle **33** is returned to the upright position, handle **33** cannot rotate around attachment joint **230**. Body **1** includes

collar **235**. When handle **33** is in the upright position, the attachment joint **230** is contained within collar **235** of body **1**. In this position, attachment joint **230** cannot rotate, as collar **235** constrains the movement of handle **33**. From the upright position, the only available direction of rotation for handle **33** is rotation between the upright and sweeping positions. When handle **33** is rotated down into a sweeping position, handle **33** can be rotated around attachment joint **230** by up to 90 degrees to either the right or left. However, in sweeping positions close to the upright position, rotation about attachment joint **230** may be constrained by collar **235**.

FIGS. **12a** and **12c** depict rotation of handle **33** by 90 degrees around attachment joint **230**. The resulting offset of handle **33** from its original axis can be expressed as an angular offset that corresponds to the plane angles indicated in FIGS. **12a** and **12c**. The amount of angular offset is determined by the axis of rotation for attachment joint **230** relative to the axial direction of the handle. In an embodiment, rotation of handle **33** by 90 degrees around attachment joint **230** results in an angular offset of 30 degrees relative to the original axis of handle **33**.

As will be apparent particularly from FIG. **3**, the bristles of the brush arrangement **11** extend outwardly from the aperture in the forward compartment **9**. In order to remove stubborn debris and/or to revitalise carpet the lower front region of the forward compartment may be chamfered, or the front region of the forward compartment may be movable (including removable), to increase the exposure of the bristles in this region. In this way, the forward part of the apparatus may be inclined relative to the surface to be cleaned, thereby increasing contact between the bristles and a surface to be cleaned and, on some surfaces, increasing the depth to which the bristles penetrate and clean the surface.

Although not shown, an auxiliary rotary brush may be provided at that side of the brush arrangement **11** which incorporates the roller **27** and the belt **29**. Such an auxiliary brush is described, for example, in GB-A-1 547 286. Such an auxiliary brush is able to sweep debris into the path of the brush arrangement **11** which might otherwise be missed due to the lack of bristles in the region of the roller **27**. The auxiliary brush may be driven by any suitable means, such as gearing from the brush arrangement **11** or by friction with the surface to be swept, and is suspended from and extends outwardly beyond the body **1**. The auxiliary brush may comprise a cylindrical body rotatable about an axis which is inclined to the vertical by about 10 degrees so as to extend outwardly beyond the body **1**. Bristles protrude radially outwardly from the periphery of the cylindrical body, but need not be perpendicular to the axis of rotation and may preferably be at an angle of about 80 degrees to the axis of rotation so as to form a cone which increases in cross-section with increasing distance from the body **1**.

Although not shown, the front part of the forward compartment **9** may be removed to expose the bristles at the front of the apparatus. This effectively increases the aperture in the forward compartment which would seriously impair the effectiveness of a suction cleaner, but in the present invention can effectively be used to assist in the sweeping of stairs, cleaning upholstery and carpets in vehicles and the like operations where a greater exposed area of bristles can be useful. As an alternative to removing the front part of the compartment **9**, the front part may be movable, for example pivotable or slidable, relative to the remainder of the compartment in order to expose the bristles.

Although not shown, the rear compartment **3** may be provided with ground-engaging wheels in order to assist

mobility of the surface cleaning apparatus. The ground-engaging wheels may, for example, be formed externally in the side regions of the rear compartment **3** or may be provided within recesses formed at least partly beneath the rear compartment **3**.

Although the illustrated embodiments of the present invention are intended primarily for domestic use, the surface cleaning apparatus can also be used outdoors or in workshops if desired. However, it may be preferable to provide a more rugged design specifically adapted for such use.

In use of the surface cleaning apparatus according to the invention, as shown in FIGS. **1** and **2**, the apparatus is placed upon a surface to be swept, such as a carpet, and the switch operated to energise the motor and consequently to rotate the brush arrangement to sweep debris from the surface and then propel the debris up and over the inclined wall **15** and into the intermediate compartment **17** where it is temporarily stored. As the surface cleaning apparatus is moved over the surface with the brush arrangement **11** rotating, any further debris is similarly swept from the surface and propelled up and over the wall **15** and into the intermediate compartment **17**. The surface cleaning apparatus is extremely portable and can be employed wherever it may be required. For example, it can be used to sweep stairs without the need for electrical leads or suction hoses. The shape of the apparatus with the rounded shape of the rear compartment as illustrated facilitates movement of the apparatus over stairs, but ground engaging wheels may be provided to further facilitate such sweeping operations.

When the intermediate compartment **17** is to be emptied, one wall of the compartment is removed as explained above and the debris can readily be discharged. The removable wall is then replaced. Alternatively, the intermediate compartment may be in the form of a tray which can be removed and emptied so as to discharge debris.

When the surface cleaning apparatus is not in use it can be stored, for example either in a cupboard or the like or plugged into a main supply in order to recharge the battery **7**.

Thus the surface cleaning apparatus of the present invention incorporates an electrically driven brush arrangement. The brush arrangement is not driven by frictional forces between the surface cleaning apparatus and the surface over which it is to be moved. Thus, efficiency of the apparatus is not dependent on the nature of the frictional contact. Further, the apparatus does not rely on suction means to draw the debris into a storage chamber. Thus, efficiency of the apparatus is not dependent on the effectiveness of suction means and the substantial power drain of suction means on the rechargeable battery is avoided. The provision of the motor at the rear of the apparatus eliminates the need for increased height should the motor be positioned over the compartment for collecting dust and the like and also provides effective full width cleaning which would not be possible if the motor was to be positioned within the compartment for collecting debris. In such a position, debris is likely to accumulate around the motor and cause blockages. In an embodiment, the invention overcomes this problem by passing the drive means for the brush arrangement at least partly through the debris compartment.

Referring to FIGS. **4**, **5** and **6**, apparatus **102** for cleaning a surface **104** by sweeping comprises a housing **106**, suitably of moulded plastic materials, and effectively having three compartments. A rear compartment **108** houses an electric motor **110** and a rechargeable battery pack **112**. The battery pack **112** may be connected to a main power supply (not

shown) for recharging the battery pack. The battery pack may either be connected to the main supply whenever the apparatus is not in use or at suitable times when the battery pack has become depleted. Switch means **113** is provided to permit a user to energise and de-energise the motor **110** as desired. As an alternative to a rechargeable battery pack, the apparatus could employ disposable batteries or be main powered.

A forward compartment **114** houses a transversely-arranged elongate rotatable brush arrangement **116**, with bristles **118**. Such elongate rotatable brush arrangement **116** is sometimes known as a brush bar. The bottom of the forward compartment **114** is open at **120** to allow the bristles **118** of the elongate brush arrangement **116** to contact a floor, carpet or the like over which the apparatus is to be propelled. The rear of the forward compartment is a rearwardly inclined wall **122** which allows debris, such as dust, dirt and the like to be propelled up the wall due to rotation of the brush arrangement **116** and to pass over the wall into an intermediate compartment **124**. The front of the forward compartment is provided with a cover (not shown) which may be removable if desired. Debris accumulating in the intermediate compartment **124** can be removed by opening a cover **126**. The wall **122** extends upwardly to about the same height as the top of the elongate brush arrangement **116** and may be angled rearwardly (i.e. away from the forward compartment) such as at an angle of about 18 degrees. The precise angle is not important, but the inclination facilitates the passage of the debris up and over the wall **122** and at the same time facilitates retention of the debris within the intermediate compartment **124**.

The elongate brush arrangement **116** is rotated by the motor **110** by way of toothed rollers **128**, **130** attached to the motor and to the brush arrangement, respectively, and by way of a toothed belt **131**, for example of elastomeric material, extending around the two rollers. The toothed belt **131** is enclosed within a tunnel **132** where it passes through or alongside the intermediate compartment **124** in order to prevent the ingress of debris into the rear compartment **108**.

An auxiliary brush means **134** is provided extending outwardly from the housing **106** at the right hand side of the elongate rotatable brush arrangement **116** as viewed from above and behind the apparatus **102**. The auxiliary brush means **134** is of substantially circular form and is supported for rotation about an axis **136**, which may be vertical or inclined to vertical, such as at an angle of about 10 degrees to vertical. The auxiliary brush means **134** has a body **138** provided with radial bristles **140** which are inclined at an acute angle to the axis of rotation **136** so as to effectively form a conical arrangement increasing in cross-section with increasing distance from the body **138**.

The auxiliary brush means **134** is rotatably driven from the rotating elongate brush arrangement **116** by a gear wheel **142** at the end of the elongate brush arrangement **116** which meshes with a further gear wheel **144** on the body **138** of the auxiliary brush means **134**. The auxiliary brush means **134** is caused to be rotated in an anti-clockwise direction denoted by arrow **146**, as viewed from above and behind the apparatus **102**. During such rotation of the auxiliary brush means **134**, a peripheral region thereof rotates from a sideways-directed position **148** (FIG. **6**) outside the housing **106** to an opposed sideways-directed position **150** covered by the housing **106**, through a forwardly-directed position **152**.

The apparatus **102** is provided with a handle **154** by means of which it can be propelled at least in a forwards direction **156**. Wheels **158** and **160** are provided to enable or assist manual propulsion of the apparatus across the surface

**104** to be swept, such as a floor, stairway or upholstery. The handle **154** could be longer, or be of a different shape or form, as required.

The rotating auxiliary brush means **134** does not rely on contact with the surface **104** for its rotation and therefore provides more efficient sweeping of edge regions of the surface **104** regardless of the nature of the surface **104**. Furthermore, the direction of rotation **146** of the auxiliary brush means **134** ensures that debris is swept positively by the auxiliary brush arrangement **134** into a position ahead of the rotating elongate rotating brush assembly **116**, ready to be picked up by the elongate brush arrangement **116**.

If desired, instead of or in addition to the auxiliary brush means **134** provided extending outwardly from the right hand side of the housing **106**, a similar auxiliary brush means (not shown) could likewise be provided extending outwardly from the left hand side of the housing **106** and driven from the opposite end of the elongate brush arrangement **116**. Such additional or alternative auxiliary brush means differs from the auxiliary brush means **134** only in that it is caused to rotate in a clockwise, rather than anti-clockwise, direction as viewed from above and behind the apparatus **102**.

Instead of the apparatus **102** being provided with a battery or main powered electric motor **110** to drive the elongate brush arrangement **116** and hence the auxiliary brush means **134**, a known form of friction drive means (not shown), resulting from propulsion of the apparatus **102** along the surface **104**, may be utilised to effect rotation of the elongate brush arrangement **116** and hence rotation of the auxiliary brush means **134**.

An alternative embodiment of apparatus according to the present invention is shown in FIG. 7. Such alternative embodiment comprises an upright vacuum cleaner apparatus **102A**, having a housing **106A** with wheels **158A** and **160A**, a rotating elongate brush arrangement **116A** and an auxiliary brush means **134A**. The apparatus **102A** is constructed in substantially similar manner to the apparatus **102** of FIGS. 4, 5 and 6, with the main exception that instead of the debris-collecting compartment **124** of FIG. 5, a debris-collecting container **124A**, which may include a bag, is provided between a handle **154A** and the housing **106A** and connected by a well-known form of suction arrangement (not shown) to the housing **106A**.

A further embodiment of apparatus **102B** according to the present invention is shown in FIG. 8. Here the housing **106B** incorporates components similar to those of the housing **106** of FIGS. 4, 5 and 6 including wheels **158B** and, in particular, an elongate rotating brush arrangement **116B** with an auxiliary rotating brush means **134B** driven therefrom. However, no debris-collecting compartment is provided inside the housing **106B**. Instead, the housing **106B** is provided with a tubular portion **162** which is demountable on, or may be fixed to, a debris-receiving flexible hose **164** connected to a well-known form of suction vacuum cleaner **166**, which may be of cylinder form, mounted on wheels **168**. Electrical wiring **170** can be incorporated in the hose **164** by means of which main electrical power can be supplied from the vacuum cleaner **166**, and through a connector **172** and wiring **174** in the tubular portion **162**, to an electric motor **110B** where provided in the housing **106B** for driving the elongate rotating brush arrangement **116B** and the auxiliary brush means **134B**. Of course, such wiring **170** would be unnecessary where the elongate brush arrangement **116B** and the auxiliary brush means **134B** driven therefrom, is caused to be rotated by the friction means previously described. Alternatively, the elongate brush arrangement

**116B** and the auxiliary brush means **134B** may be caused to be rotated by means of a (rechargeable) battery or an air turbine driven by air passing along the tubular portion **162**. The housing **106B** with its included components could be provided as an accessory for existing vacuum cleaners of cylinder form.

In some embodiments, the sweeper also includes a cleaning strip. The cleaning strip assembly **2** as shown in FIG. 13 comprises an elongate support member **4** comprising a flexible material, for example rubber or a plastic material, with a substantially circular cross-section. Formed integral with the elongate member **4** are a series of spaced apart flexible tabs **6**. Also formed integral with the elongate member **4** is a flexible strip **8** positioned along substantially the entire length of the elongate member. The thickness of the flexible strip **8** decreases progressively towards an edge furthest from the elongate member. The flexible strip need not be integral with the elongate support member **4**. As an alternative, the support member **4** may be formed with a recessed groove extending in the axial direction and the flexible strip **8** may be formed with a projection of complementary configuration to retain the flexible strip in the groove. The groove and the projection may conveniently be substantially T-shaped.

The flexible strip may have any convenient length, for example in the range from 2.5 to 8 mm. However, a length of substantially 4.5 mm has been found to be particularly suitable.

The flexible tabs **6** and the flexible strip **8** are positioned on the elongate member substantially at an angle relative to each other of approximately 45 degrees. The flexible tabs and flexible strip extend in a generally radial direction from the elongate member, and are directed, in use, towards the lower face of the body of the surface cleaning apparatus.

The elongate member of the cleaning strip assembly is housed within a cavity in the underside of the wall **15** of the surface cleaning apparatus so as to be rotatable about the axis of the elongate member. FIG. 15 depicts an embodiment of a surface cleaning apparatus that incorporates a cleaning strip assembly. The cleaning strip assembly is oriented such that the flexible strip is nearest to the front of the surface cleaning apparatus and the flexible tabs are nearer to the rear of the surface cleaning apparatus. The cavity has an open face through which the flexible strip and the flexible tabs protrude. As shown in FIG. 15, the cavity has a first major wall **28**, the rear wall in use, which is substantially upright, and a second major wall **30**, the front wall in use, is inclined away from the rear wall at a nominal angle of 60 degrees. The inner face of the cavity, opposite the opening **32**, is in the form of a concave curved surface wherein the curvature complements the curvature of the elongate member. The elongate member is retained within the cavity by retaining tabs attached to the rear wall of the cavity at the open face of the cavity. The cavity in the wall **15** is shaped such that excessive rotation of the elongate member in either direction is prevented by the walls of the cavity engaging the flexible tabs or flexible strip.

Lateral movement of the elongate member may be inhibited by any suitable means. For example a cover for part of the drive mechanism may be provided with a protrusion which extends sufficiently to cover the end of the elongate member. Removal of the cover then exposes the end of the elongate member and allows it to be removed, for example for replacement.

FIG. 14 shows an alternative embodiment of the cleaning strip assembly in which the flexible strip has a first section **10** and a second section **12** positioned close to a first end **14**

## 11

and to a second end **16**, respectively, of the elongate member **4** at which material of the flexible strip is absent such that an isolated portion **20** of the flexible strip is provided at the ends **14**, **16** of the elongate member. In use, the isolated portions **20**, in conjunction with restraining pins **18** provided on the ends **14**, **16** of the elongate member, impinge on retaining tabs of the cavity, such that the ends of the elongate member are prevented from being pulled towards each other during flexure of the elongate member.

The cleaning strip assembly **2** is used to ensure that efficient cleaning of surfaces, for example hard floor surfaces, is achieved. As shown in FIG. **15A**, when the surface cleaning apparatus is pushed forward **24** over a surface **104** to be cleaned, the flexible tabs **6** of the cleaning strip respond to movement of the apparatus by being dragged backwards by friction with the floor causing the elongate member **4** to rotate about its axis. Rotation of the elongate member brings the flexible strip **8** into contact with the floor. Continued forward movement of the surface cleaning apparatus results in the flexible strip being held in contact with the surface and particles of dirt **103** on the surface to be cleaned are gathered together and pushed forward along with the movement of the surface cleaning apparatus. Excessive rotation of the elongate member **4**, when the surface cleaning apparatus is pushed forwards **24**, is prevented by the rear face of the flexible strip engaging on the retaining tabs **22** which retain the elongate member within the cavity **32** of the wall **15**. Further rotation is also prevented by the flexible tabs **6** engaging the rear wall **28** of the cavity **32**.

FIG. **15B** shows, when the surface cleaning apparatus is moved in a rearward direction **26**, the flexible strip **8** responds to movement of the apparatus by being dragged towards the front of the surface cleaning apparatus by friction with the surface **104** to be cleaned. In dragging the flexible strip forwards, the elongate member **4** of the cleaning strip assembly is rotated such that the flexible tabs **6** are brought into contact with the floor **104**. The flexible tabs **6** are also dragged towards the front of the surface cleaning apparatus so resulting in continued rotation of the elongate member and the subsequent lifting of the flexible strip clear of the floor. Excessive rotation of the elongate member is prevented by the flexible strip engaging the inclined front wall **30** of the cavity **32** in wall **15** and being stopped from further forward movement. When the surface cleaning apparatus is pulled in a rearward direction, the particles of dirt gathered together by the flexible strip during use in the forward direction are swept from the surface by the brush arrangement and propelled up and over the wall **15** and into the intermediate compartment **17**. As the flexible strip is clear of the floor, additional particles of dirt can pass between adjacent flexible tabs and are not prevented from passing under the flexible strip.

The surface cleaning apparatus is extremely portable and can be employed wherever it may be required. For example, it can be used to sweep stairs without the need for electrical leads or suction hoses. The shape of the apparatus with the rounded shape of the rear compartment as illustrated facilitates movement of the apparatus over stairs, but ground engaging wheels may be provided to further facilitate such sweeping operations.

When the surface cleaning apparatus is not in use, it can be stored, for example either in a cupboard or the like or plugged into a main supply in order to recharge the battery **7**.

Thus the illustrated surface cleaning apparatus incorporating the cleaning strip assembly of the present invention incorporates an electrically driven brush arrangement. The

## 12

brush arrangement is not driven by frictional forces between the surface cleaning apparatus and the surface over which it is to be moved. Thus, efficiency of the apparatus is not dependent on the nature of the frictional contact. Further, the apparatus does not rely on suction means to draw the debris into a storage chamber. Thus, efficiency of the apparatus is not dependent on the effectiveness of suction means and the substantial power drain of suction means on the rechargeable battery is avoided. The provision of the motor at the rear of the apparatus eliminates the need for increased height should the motor be positioned over the compartment for collecting dust and the like and also provides effective full width cleaning which would not be possible if the motor was to be positioned within the compartment for collecting debris. In such a position, debris is likely to accumulate around the motor and cause blockages. The illustrated apparatus overcomes this problem by passing the drive means for the brush arrangement at least partly through the debris compartment.

Although the cleaning strip assembly described hereinbefore is shown as comprising an elongate member with a substantially circular cross-sectional area having attached thereto at least one tab and a strip member, it should be appreciated that the cleaning strip assembly may take other embodiments and the moving of the strip member relative to a floor may be achieved by other methods rather than by rotation of the elongate body of the cleaning strip assembly.

FIG. **16** shows another embodiment of a cleaning strip assembly **202** which comprises an elongate member **204** of rigid material, for example plastic material, which is attached to a flexible strip **208**, for example of a plastic or rubber material, positioned along substantially the entire length of the elongate member **204**. The thickness of the flexible strip **208** decreases progressively towards an edge furthest from the elongate member. The thickness of the flexible strip is less than that of the elongate body such that a shoulder portion **210** is formed either side of the flexible strip where it is attached to the elongate member.

The flexible strip is directed, in use, towards the lower face of the body of the surface cleaning apparatus.

The elongate member of the cleaning strip assembly is housed within the cavity (not shown) in the underside of the wall **15** of the surface cleaning apparatus so as to be movable in a substantially upright plane relative to the floor. The cavity also contains an arm **212** fixed at one end to a pivot pin **214** which can rotate about a fixed axis within the cavity. In use, the fixed axis of the pivot pin **214** is substantially parallel to the surface of the floor. The end of the arm **212** furthest from the pivot pin is positioned beneath a shoulder portion **210** of the cleaning strip assembly. Also attached to the pivot pin **214** within the cavity are a number of flexible tabs **206**. The free end of each tab **206**, in use, is in contact with the floor **104**.

The cavity has an open face through which the flexible strip and the flexible tabs protrude. The elongate member **204** is retained within the cavity by means of the arm **212** positioned below the shoulder portion **210** of the cleaning strip assembly.

As shown in FIG. **16A**, when the surface cleaning apparatus is pushed forward as shown by the arrow **24** over a surface **104** to be cleaned, the flexible tabs **206** of the cleaning strip assembly are dragged backwards by friction with the floor causing the arm **212** to pivot about the fixed axis of the pivot pin **214** towards the floor. Pivoting of the arm away from the shoulder portion **210** of the cleaning strip assembly allows the elongate member of the cleaning strip assembly to lower and bring the flexible strip **208** into

13

contact with the floor. Particles of dirt **103** on the surface to be cleaned are gathered together by the flexible strip and pushed forward along with the movement of the surface cleaning apparatus.

FIG. **16B** shows, when the surface cleaning apparatus is moved in a rearward direction as shown by the arrow **26**, the flexible tabs are dragged toward the front of the surface cleaning apparatus by friction with the surface **104** to be cleaned. In dragging the flexible tabs forward, the arm **212** pivots away from the floor about the fixed axis of the pivot pin **214**. The arm **212**, positioned under the shoulder **210** of the cleaning strip assembly, urges the cleaning strip assembly in a substantially upward direction such that the flexible strip **208** is lifted clear of the floor.

When the surface cleaning apparatus is pulled in a rearward direction, the particles of dirt gathered together by the flexible strip during use in the forward direction are swept from the surface by the brush arrangement. As the flexible strip is clear of the floor, additional particles of dirt can pass between adjacent flexible tabs and are not prevented from passing under the flexible strip.

FIG. **17** shows a further embodiment of the cleaning strip assembly, wherein the cleaning strip assembly comprises an elongate member **204** of rigid material, for example plastics material, which is attached to a flexible strip **208** positioned along substantially the entire length of the elongate member. The thickness of the flexible strip **208** decreases progressively towards an edge furthest from the elongate member. The thickness of the flexible strip is less than that of the elongate body such that a shoulder portion **210** is formed either side of the flexible strip where it is attached to the elongate member.

The cavity also contains a first arm **212** fixed at one end to a pivot pin **214** which can rotate about a first fixed axis within the cavity. The end of the first arm **212** furthest from the pivot pin **214** is positioned beneath a shoulder portion **210** of the cleaning strip assembly. Also attached to the pivot pin within the cavity are a number of flexible tabs **206**. The free end of each tab **206**, in use, is in contact with the floor **104**.

Attached to the elongate body **204** is a second arm **216** which connects the cleaning strip assembly **202** to a second pivot pin **218** within the cavity in the wall of the surface cleaning apparatus. The elongate member of the cleaning strip assembly is housed within the cavity of the surface cleaning apparatus so as, when in use, to be pivotably moved on the second arm **216** relative to the floor about an axis of the second pivot pin **218** substantially parallel with the surface of the floor.

The cavity comprises an open face through which the flexible strip and the flexible tabs protrude. The elongate member is retained within the cavity by means of the first arm **212** positioned below the shoulder portion **210** of the cleaning strip assembly and by means of the second arm **216** attaching the cleaning strip assembly to the second pivot pin **218**.

When the surface cleaning apparatus is pushed forward **24** over a surface **104** to be cleaned, the flexible tabs **206** of the cleaning strip assembly are dragged backwards by friction with the floor causing the first arm **212** to pivot towards the floor about the axis of the first pivot pin **214**. Pivoting of the first arm **212** allows the elongate member of the cleaning strip assembly to pivot on the second arm **216** about the axis of the second pivot pin **218** and so bring the flexible strip **208** into contact with the floor. As described hereinabove, particles of dirt **103** on the surface to be cleaned are gathered

14

together by the flexible strip and pushed forward along with the movement of the surface cleaning apparatus.

When the surface cleaning apparatus is moved in a rearward direction the flexible tabs are dragged towards the front of the surface cleaning apparatus by friction with the surface **104** to be cleaned. In dragging the flexible tabs forward, the first arm **212** pivots away from the floor about the axis of the first pivot pin **214**. The first arm, positioned under the shoulder **210** of the cleaning strip assembly, urges the cleaning strip assembly in a substantially upward direction such that the flexible strip is lifted clear of the floor and pivots, via the second arm **213**, about the axis of the second pivot pin **218**.

When the surface cleaning apparatus is pulled in a rearward direction, the particles of dirt gathered together by the flexible strip during use in the forward direction are swept from the surface by the brush arrangement. As the flexible strip is clear of the floor, additional particles of dirt can pass between adjacent flexible tabs and are not prevented from passing under the flexible strip.

It should be understood that an alternative to the flexible tabs described hereinabove could be a friction wheel **220**, as shown in FIG. **18**, whereby movement of the friction wheel **220** relative to the floor can be used to cause an arm **212** beneath the shoulder portion **210** of the cleaning strip assembly to be moved thus raising and lowering the cleaning strip assembly as described hereinabove.

It should be understood that electronic or other means may be used in place of frictional means to determine the movement of the surface cleaning apparatus and for controlling the positioning of the flexible strip.

The foregoing disclosure has been set forth merely to illustrate the invention and is not intended to be limiting. Since modifications of the disclosed embodiments incorporating the spirit and substance of the invention may occur to persons skilled in the art, the invention should be construed to include everything within the scope of the appended claims and equivalents thereof.

What is claimed is:

1. A surface cleaning apparatus, comprising:

- a) a body having a forward compartment and rear compartment;
- b) an elongate rotatable brush extending across the forward compartment;
- c) an electric motor for driving the rotatable brush ; and
- d) a handle movable between an upright position and steering positions by rotation about an axis transverse to the axial direction of the handle, said handle being further rotatable around a second axis in said steering positions said second axis of rotation being offset from the axial direction of the handle,

wherein the body further comprises a collar that prevents rotation of the handle around said second axis in the upright position.

2. The apparatus of claim 1, further comprising an auxiliary brush extending from the forward compartment and driven by the motor.

3. The apparatus of claim 2, wherein the elongate rotatable brush and auxiliary brush are driven by the electric motor.

4. The apparatus of claim 3, wherein the auxiliary brush and the elongate rotatable brush are connected by a gear.

5. The apparatus of claim 1, further comprising an intermediate compartment defined by a wall between the forward compartment and the intermediate compartment, a wall between the intermediate compartment and the rear compartment, and side walls.

## 15

6. The apparatus of claim 5, wherein one side wall is removable to facilitate removal of debris.

7. The apparatus of claim 6, wherein the removable side wall includes a cover.

8. The apparatus of claim 5, wherein the intermediate compartment includes a tray that can be removed and emptied so as to discharge debris.

9. The apparatus of claim 5, wherein the intermediate compartment is a removable tray having at least one wall that forms a wall of said body.

10. The apparatus of claim 5, wherein the belt is enclosed within a tunnel that passes through the intermediate compartment.

11. The apparatus of claim 10, wherein one side wall is removable to facilitate removal of debris and the tunnel is arranged at a side remote from the removable side wall.

12. The apparatus of claim 5, wherein the wall between the forward and intermediate compartments is inclined rearwardly.

13. The apparatus of claim 12, wherein the wall between the forward and intermediate compartments has an angle of inclination of from 15 to 20 degrees.

14. The apparatus of claim 5, wherein the wall between the intermediate and rear compartments seals the rear compartment from the intermediate compartment.

15. The apparatus of claim 1, wherein a front part of the forward compartment is movable to expose bristles on the elongate rotatable brush at the front part of the forward compartment.

16. The apparatus of claim 1, wherein the rear compartment is provided with ground-engaging wheels.

17. The apparatus of claim 1, further comprising a cleaning strip assembly pivotably mounted on an underside of the body.

18. The apparatus of claim 17, wherein the cleaning strip assembly comprises an elongate support member and a flexible strip extending radially from the support member.

19. The apparatus of claim 18, wherein the elongate support member extends along substantially the entire length of the body.

20. The apparatus of claim 17, wherein the cleaning strip assembly further comprises at least one tab oriented to contact the surface being cleaned during cleaning.

21. The apparatus of claim 20, wherein the at least one tab is oriented so that contact of the at least one tab with the surface being cleaned is capable of causing the cleaning strip assembly to pivot between a cleaning position and an elevated position.

22. The apparatus of claim 1, wherein the forward compartment further comprises an opening in a lower surface thereof, and wherein a lower front region of the body is chamfered so that bristles of the elongate brush protrude from the body in the region of the chamfer such that, when the apparatus is inclined relative to a surface to be cleaned, contact between the bristles and the surface to be cleaned is increased.

## 16

23. A surface cleaning apparatus, comprising:

a) a body having a forward compartment and rear compartment;

b) an elongate rotatable brush extending across the forward compartment;

c) an electric motor for driving the rotatable brush;

d) an intermediate compartment comprising a removable tray, wherein at least one side of the removable tray forms a wall of said body; and

e) a handle movable between an upright position and steering positions by rotation about an axis transverse to the axial direction of the handle, said handle being further rotatable around a second axis in said steering positions said second axis of rotation being offset from the axial direction of the handle, and the body further comprises a collar that prevents rotation of the handle about the axis offset from the axial direction of the handle in an upright position.

24. The apparatus of claim 23, further comprising an auxiliary brush extending from the forward compartment and driven by the electric motor.

25. The apparatus of claim 24, wherein the auxiliary brush and the elongate rotatable brush are connected by a gear.

26. The apparatus of claim 25, wherein one side wall is removable to facilitate removal of debris.

27. The apparatus of claim 23, wherein the removable tray includes a cover.

28. The apparatus of claim 23, wherein the belt is enclosed within a tunnel that passes through the intermediate compartment.

29. The apparatus of claim 28, wherein the tunnel is arranged at a side remote from said side of the removable tray that forms a wall of said body.

30. The apparatus of claim 23, wherein the wall between the forward and intermediate compartments is inclined rearwardly.

31. The apparatus of claim 30, wherein the wall between the forward and intermediate compartments has an angle of inclination of from 15 to 20 degrees.

32. The apparatus of claim 23, wherein the wall between the intermediate and rear compartments seals the rear compartment from the intermediate compartment.

33. The apparatus of claim 23, wherein a front part of the forward compartment is movable to expose bristles on the elongate rotatable brush at the front part of the forward compartment.

34. The apparatus of claim 23, wherein the rear compartment is provided with ground-engaging wheels.

35. The apparatus of claim 23, wherein the forward compartment further comprises an opening in a lower surface thereof, and wherein a lower front region of the body is chamfered so that bristles of the elongate brush protrude from the body in the region of the chamfer such that, when the apparatus is inclined relative to a surface to be cleaned, contact between the bristles and the surface to be cleaned is increased.
