APPLICATION DATA

This application is a continuation of U.S. application Ser. No. 10/630,599 filed Jul. 30, 2003, now abandoned which claims benefit to U.S. provisional application Ser. No. 60/403,422 filed Aug. 14, 2002.

TECHNICAL FIELD OF THE INVENTION

The present invention relates to methods of using p38 kinase inhibitors in the treatment of diseases related to blood coagulation and fibrinolysis.

BACKGROUND OF THE INVENTION

Activation of the coagulation system is an important manifestation of the systemic inflammatory response of the host to infection. Levi M, et. al. 1999 *N Engl J Med.*; 341:586-592. Several in vivo models have been used to dissect the molecular mechanisms that contribute to coagulation activation by bacteria and bacterial products, including intravenous injection of low dose lipopolysaccharide (LPS) into healthy humans. Van der Poll T et. al., 1999 Cohen J, Marshall J, ed. *The Immune Response in the Critically Ill. Berlin: Springer-Verlag*; 335-357. Tissue factor, a glycoprotein expressed on endothelial cells and monocytes upon stimulation, plays an essential role in coagulation activation induced by LPS or bacteria in vivo, as demonstrated by abolishment of this response by inhibitors of tissue factor. de Jonge E, et. al., 2000 *Blood* 95:1124-1129; Creasey A A, et. al. 1993 *J Clin Invest.*; Carr C, et al. 1994 *Circ Shock.* 44:126-137; Levi M, et al. 1994 *J Clin Invest.* 93:114-120. Mitogen-activated protein kinases (MAPKs), such as p38 MAPK, participate in intracellular signaling cascades that mediate inflammatory responses to infectious and noninfectious stimuli. Herlaar E, et al. 1999 *Mol Med Today* 5:439-447; Ono K, et. al. 2000 *Cell Signal* 12:1-13. Recent in vitro studies have implicated one of these kinases, p38 MAPK, in the regulation of tissue factor expression on monocytes, endothelial cells, and smooth muscle cells. Chu A J, et al. 2001 *J Surg Res.* 101:85-90. Blum S, et al. 2001 *J Biol. Chem.* 276:33428-33434; Eto M, et. al. 2002 *Circulation* 105:1756-1759; Herkert O, et. al. 2002 *Circulation*; 105:2030-2036.

For the most part, such compounds have been indicated as being useful in treating cytokine mediated diseases such as those related to inflammation. Marin et al discusses the issue of whether p38 MAPK is involved in thrombin-induced endothelial proinflammatory functions including chemokine production. *Blood*, 1 Aug. 2001, Vol. 98 (3) 667-673. Until the present invention however, knowledge of the role of p38 MAPK in activation of coagulation and fibrinolysis has not been available.

SUMMARY OF THE INVENTION

In view of the work cited above there is a clear need for a method of treating diseases or conditions related to coagulation using small molecule inhibitors such as those which inhibit p38 MAP kinase.

It is therefore an object of the invention to provide a method of anticoagulant and fibrinolytic therapy using inhibitors of p38 MAP kinase either for prevention or for treatment of these hematological physiologic processes in disease states where their activation may cause harm.

DETAILED DESCRIPTION OF THE
PREFERRED EMBODIMENTS

This administration may be of benefit given either prophylactically to patients at risk or therapeutically for patients who have developed complications related to these pathways.

or the pharmaceutically acceptable salts thereof.

Particularly preferred, the p38 kinase inhibitors is:

Formula (III)

and the pharmaceutically acceptable derivatives thereof.

Any reference to the abovementioned p38 kinase inhibitors include "pharmaceutically acceptable derivative" thereof which refers to any pharmaceutically acceptable salt or ester of a compound of this invention, or any other compound which, upon administration to a patient, is capable of providing (directly or indirectly) a p38 kinase inhibitor of this invention, a pharmacologically active metabolite or pharmacologically active residue thereof. A pharmacologically active metabolite shall be understood to mean any compound capable of being metabolized enzymatically or chemically. This includes, for example, hydroxylated or oxidized derivative p 38 compounds.

Pharmaceutically acceptable salts of the compounds of this invention include those derived from pharmaceutically acceptable inorganic and organic acids and bases. Examples of suitable acids include hydrochloric, hydrobromic, sulfuric, nitric, perchloric, fumaric, maleic, phosphoric, glycolic, lactic, salicylic, succinic, toluene-p-sulfuric, tartaric, acetic, citric, methanesulfonic, formic, benzoic, malonic, naphthalene-2-sulfuric and benzenesulfonic acids. Other acids, such as oxalic acid, while not themselves pharmaceutically acceptable, may be employed in the preparation of salts useful as intermediates in obtaining the compounds of this invention and their pharmaceutically acceptable acid addition salts. Salts derived from appropriate bases include alkali metal (e.g., sodium), alkaline earth metal (e.g., magnesium), ammonium and N-(C₁-C₄ alkyl)₄⁺ salts.

In addition, the compounds of this invention include prodrugs of p38 compounds. Prodrugs include those compounds that, upon simple chemical transformation, are modified to produce compounds of the invention. Simple chemical transformations include hydrolysis, oxidation and

reduction. Specifically, when a prodrug of this invention is administered to a patient, the prodrug may be transformed into a p38 kinase inhibitor compound thereby imparting the desired pharmacological effect.

For prophylactic or therapeutic use, the pharmaceutical p38 kinase inhibitor compounds according to the invention may be administered in any conventional dosage form in any conventional manner. Routes of administration include, but are not limited to, intravenously, intramuscularly, subcutaneously, intrasynovially, by infusion, sublingually, transdermally, orally, topically or by inhalation. The preferred modes of administration are oral and intravenous.

p38 kinase inhibitors according to the invention may be administered separately, or in a combination formulation with adjuvants that enhance stability of the inhibitors, facilitate administration of pharmaceutical compositions containing them in certain embodiments, provide increased dissolution or dispersion, increase inhibitory activity, provide adjunct therapy, and the like, including other active ingredients. For combination therapy with the drugs listed hereinbelow, advantageously, such combination therapies utilize lower dosages of the conventional therapeutics, thus avoiding possible toxicity and adverse side effects incurred when those agents are used as monotherapies. p38 kinase inhibitors may therefore be physically combined with the conventional therapeutics or other adjuvants into a single pharmaceutical composition. Regarding pharmaceutical compositions, reference may be made to Cappola et al.: U.S. patent application Ser. No. 09/902,822, PCT/US 01/21860 and U.S. provisional application No. 60/313,527, each incorporated by reference herein in their entirety. The optimum percentage (w/w) of a compound of the invention may vary and is within the purview of those skilled in the art.

As mentioned above, dosage forms of the compositions described herein include pharmaceutically acceptable carriers and adjuvants known to those of ordinary skill in the art. These carriers and adjuvants include, for example, ion exchangers, alumina, aluminum stearate, lecithin, serum proteins, buffer substances, water, salts or electrolytes and cellulose-based substances. Preferred dosage forms include, tablet, capsule, caplet, liquid, solution, suspension, emulsion, lozenges, syrup, reconstitutable powder, granule, suppository and transdermal patch. Methods for preparing such dosage forms are known (see, for example, H. C. Ansel and N. G. Popovich, *Pharmaceutical Dosage Forms and Drug Delivery Systems*, 5th ed., Lea and Febiger (1990)). Dosage levels and requirements are well-recognized in the art and may be selected by those of ordinary skill in the art from available methods and techniques suitable for a particular patient. p38 kinase inhibitor, in some embodiments, dosage levels range from about 1-1000 mg/dose for a 70 kg patient. Although one dose per day may be sufficient, up to 5 doses per day may be given. For oral doses, up to 2000 mg/day may be required. Reference in this regard may also be made to U.S. provisional application No. 60/339,249. As the skilled artisan will appreciate, lower or higher doses may be required depending on particular factors. For instance, specific dosage and treatment regimens will depend on factors such as the patient's general health profile, the severity and course of the patient's disorder or disposition thereto, and the judgment of the treating physician.

In another aspect the present invention relates to a pharmaceutical composition suitable for inhalation which contains one or more salts of a p38 kinase inhibitor, optionally in the form of their solvates or hydrates. The active substances may either be combined in a single preparation or contained in two separate formulations. Pharmaceutical

compositions which contain the active p38 kinase inhibitor substances in a single preparation are preferred according to the invention.

Anticoagulant and Fibrinolytic Activity of P38 MAP Kinase Inhibitors

It has been found for the first time that p38 MAPK has a role in activation of coagulation, fibrinolysis and the vascular endothelium. The invention therefore provides a method of anticoagulant and fibrinolytic therapy for a disease or condition relating to blood coagulation or fibrinolysis comprising administering to a patient in need thereof a pharmaceutically effective amount of a p38 MAP kinase inhibitor.

p38 MAP Kinase has been determined to have a role in the activation of the hemostatic mechanism in vivo. A possible explanation for the anticoagulant effect of p38 MAP kinase inhibitors is inhibition of tissue factor expression. Tissue factor is essential for activation of the coagulation system in this model of low grade endotoxemia^{3,6}, and p38 MAPK inhibition markedly diminished LPS-induced tissue factor expression by monocytic cells in vitro⁹. Moreover, p38 MAPK activation also mediates tissue factor expression by endothelial cells stimulated with thrombin or vascular endothelial growth factor, and by vascular smooth muscle cells stimulated with thrombin¹⁰⁻¹². Furthermore, and not mutually exclusive, the reduced IL-6 concentrations in subjects treated with a preferred p38 MAP kinase inhibitor of the formula (III) may have contributed to the attenuated coagulant response, considering that IL-6 is an important mediator of coagulation activation by LPS in vivo¹⁶.

Intravenous injection of LPS is associated with activation of the coagulation system, as reflected by a rise in the plasma concentrations of the prothrombin fragment F1+2. The effective dosage range for formula (III) is described in U.S. provisional application No. 60/339,249. High end dosing of formula (III) inhibited LPS-induced coagulation activation, both delaying and diminishing the increase in plasma F1+2 concentrations. Formula (III) had an even stronger inhibitory effect on activation of the fibrinolytic system

p38 MAP kinase inhibitors also have an effect on endothelial cell activation, reflected by the plasma concentrations of sE-selectin and vWF¹⁸⁻²⁰. Administration of LPS elicited profound increases in the plasma levels of sE-selectin and vWF, which were attenuated by high dose formula (III). p38 MAPK may play a direct role in signaling inflammatory effects into the interior of the vascular endothelium^{10,11,21}, including the expression of E-selectin on stimulated endothelial cells^{22,23}.

Methods of Therapeutic Use

p38 compounds have been discovered for the first time to be useful in anticoagulant and fibrinolytic or thrombolytic therapy. Anticoagulants are used in treating acute venous thrombosis and pulmonary embolism. Thrombosis can also occur if the form of cerebral arterial embolism from cardiac sources such as ventricular mural thrombi or atrial thrombi or from an atherosclerotic, partially stenosed carotid or vertebral artery, or peripheral or mesenteric arterial thrombosis.

These agents may also be useful in preventing or treating thrombosis during pregnancy, hemorrhagic skin necrosis, preventing or treating acute or chronic disseminated intravascular coagulation (DIC), prevention of clot formation occurring from surgery, long bed rest or long periods of immobilization such as that which occurs during air travel.

An example of a condition where an inhibitor of coagulation would be useful prophylactically is in the prevention or treatment of deep vein thrombosis (DVT). Current therapy involves anticoagulation with heparin. Venous thrombosis or thrombophlebitis is caused by the presence of thrombus within a superficial or deep vein and the accompanying inflammatory response in the vessel wall. The factors that predispose to venous thrombosis include stasis, vascular damage, and hypercoagulability and may occur in patients having orthopedic surgical procedures, particularly those involving the hip or knee, or patients who undergo abdominal or thoracic operations. The prevalence of venous thrombosis is particularly high in patients with cancer of the pancreas, lungs, genitourinary tract, stomach, and breast. Risk of thrombosis is increased following trauma, such as fractures of the spine, pelvis, femur, and tibia. Immobilization, regardless of the underlying disease, is a major predisposing cause of venous thrombosis.

An example of a disease where an agent that inhibits the fibrinolytic pathway would be useful is fulminant meningococemia. Fulminant meningococemia is perhaps the most rapidly lethal form of septic shock. Fibrinolytic therapy may also be an available treatment for patients with massive pulmonary embolism and systemic hypotension and to restore the patency of acutely occluded peripheral and coronary arteries. Timely fibrinolytic therapy may reduce both myocardial damage and mortality following acute coronary occlusion. Fibrinolytic therapy may also be effective in acute thrombotic strokes, acute coronary occlusion, acute peripheral arterial occlusion, massive pulmonary embolism with severe hypoxemia and hypotension, axillary vein thrombosis, massive iliofemoral vein thrombosis, occluded arterial or venous cannulae, cardiomyopathy, and venoocclusive disease of the liver.

Also with the scope of the invention is the combination therapy of a p38 inhibitor and one or more other anticoagulant or fibrinolytic agents. These include recombinant tissue plasminogen activator (rtPA), streptokinase (SK), urokinase (UK), proUK, heparin, enoxoparin, dalteparin, coumarin anticoagulants, aspirin, dipyridamol, aggrenox, ticlopidine, clopidogrel (Plavix), abciximab, RheoPro, integrilin, aggrestat and the like. Particular dosages, formulations and methods of administration either alone or combined is within the skill in the art.

The Examples which follow serve to illustrate the present invention in more detail without restricting the scope of the invention to the following embodiments by way of example.

Inhibition of P38 MAP Kinase

To determine binding affinities for compounds to p38 MAP kinase, a fluorescence binding assay is used as described [Pargellis, C., Tong, L., Churchill, L., Cirillo, P. F., Gilmore, T., Graham, A. G., Grob, P. M., Hickey, E. R., Moss, N., Pav, S. & Regan, J. Inhibition of p38 MAP kinase by utilizing a novel allosteric binding site. *Nature Structural Biology* 9, 268-272 (2002)]. Binding studies are conducted in aqueous solutions prepared using binding buffer: 20 mM Bis-TRIS Propane (pH 7.0), 2 mM EDTA, 0.01% NaN₃, and 0.15% n-octylglucoside. Kinetic data for the association of SK&F 86002 to p38 MAP kinase is collected on a Kintech fluorescence detector system equipped with a stopped flow controller. The data is fit simultaneously to an appropriate equation describing kinetic binding for a simple 1-step binding mechanism [Morelock, M. M., Pargellis, C. A., Graham, E. T., Lamarre, D. & Jung, G. Time-resolved ligand exchange reactions: kinetic models for competitive inhibitors with recombinant human renin. *J. Med. Chem.* 38,

65

1751-1761 (1995)]. The exchange curve assays are run as two half reactions using an SLM Aminco Bowman Series 2 Model SQ-340 fluorescence detector. Preliminary equilibrium are set up with two half reactions differing in the order of addition of the two p38 MAP kinase inhibitors. In the first half reaction, p38 MAP kinase and SK&F 86002 are preincubated for 3 minutes. In the second half reaction p38 MAP kinase is preincubated with BIRB 796 for 60 minutes. A net dissociation of the fluorescent probe, SK&F 86002, is observed for the first half reaction and a net association is observed for the second half reaction. The raw data from both half reactions are fitted simultaneously to an equation describing simple competitive inhibition [Morelock, M. M., Pargellis, C. A., Graham, E. T., Lamarre, D. & Jung, G. Time-resolved ligand exchange reactions: kinetic models for competitive inhibitors with recombinant human renin. *J. Med. Chem.* 38, 1751-1761 (1995)]. BIRB 796 (chemical name: 1-(5-tert-butyl-2-p-tolyl-2H-pyrazol-3-yl)-3-[4-(2-morpholin-4-yl-ethoxy)-naphthalen-1-yl]-urea) was synthesized as described [Cirillo, P., Gilmore, T. A., Hickey, E., Regan, J. & Zhang, L. H. Aromatic heterocyclic compounds as antiinflammatory agents. (WO0043384) Dec. 9, 1999].

Preferred compounds will have an $IC_{50} < 1 \mu M$ in this assay, confirming inhibition of p38 MAP Kinase.

EXAMPLE II

LPS Study

This study was performed as a randomized, double-blind, placebo-controlled experiment and was performed simultaneously with a study examining the effect of formula (III) on LPS-induced cytokine release and neutrophil activation¹⁴. Briefly, LPS (from *E. coli*, lot G; United States Pharmacopeial Convention, Rockville, Md.; 4 ng/kg body weight) was administered as a bolus intravenous injection to 24 healthy male volunteers (mean age 22 years, range 19-29). Three hours prior to infusion of LPS, the p38 MAPK inhibitor (III) (600 mg n=8, 50 mg n=8) or placebo (n=8) was administered orally. Blood samples were obtained before administration of (III) or placebo (t=-3 h), directly before LPS administration (t=0 h), and at several time points up to 24 hours thereafter.

Assays

Blood was collected in siliconized vacutainer tubes (Becton Dickinson, Plymouth, England) containing 0.105 M sodium citrate in a 1:9 (v/v) anticoagulant: blood ratio. ELISA's were performed according to the instructions of the manufacturers: prothrombin fragment F1+2 (Dade Behring, Marburg GmbH, Germany), tissue-type plasminogen activator (tPA)(Asserachrom tPA, Diagnostic Stago, Asnieres-sur-Seine, France), plasminogen activator inhibitor type 1 (PAI-1) (Monozyme, Charlottelund, Denmark), Von Willebrand Factor (vWF) (Dakopatts, Ävlsjö, Sweden), and soluble E-selectin (sE-selectin)(Diacclone, Besancon Cedex, France); plasmin-2-antiplasmin complexes (PAPc) were determined by a radio immunoassay as described elsewhere¹⁵.

Sepsis—Animal Models

Numerous animal models have been developed in which to simulate the clinical manifestation of septic shock in an attempt to gain further understanding of the disease state and to evaluate possible therapeutic agents. Smaller animal models such as mouse, rats and rabbits afford the investigator the advantages of a screening tool whereby results may be generated faster since larger numbers of animals can be used at one time, however, the disadvantages are that these species have reduced capacity for extensive biochemical analysis (smaller blood volume), show a higher tolerance for bacterial endotoxin (a highly antigenic portion of gram negative bacteria) and are more difficult to instrument when monitoring cardiovascular parameters. Thus, larger animal models are preferred when studying the cardiovascular response to sepsis. Specifically, primate models are described whereby continuous infusion live *E. coli* or endotoxin is used to simulate the human disease. It has been reported that intravenous administration of *E. coli* or endotoxin can result in systemic hypotension, decreased cardiac output, decreased vascular resistance, pulmonary hypertension, diminished lung compliance, leukopenia and thrombocytopenia. In addition, cardiovascular response, blood flow, leukocyte function and blood coagulation have been studied in primates.

Animal Models—Venous Thrombosis

Numerous models have also been developed to study thrombosis in animals. Rabbit or rat model of venous or arterial thrombosis are known in the literature. Two typical models are:

Rabbit deep vein thrombosis model: Briefly, a non-occlusive fibrin-rich thrombus is formed on a thrombogenic surface (cotton threads attached to copper wire) introduced into the abdominal vena cava via the femoral vein of an anesthetized rabbit.

Rabbit/rat/dog arteriovenous shunt model: Briefly, the left femoral artery and vein is isolated, cannulated with polyethylene tubing and connected with a polyethylene shunt containing a 6-cm long cotton thread. The cotton thread is removed 15 min after blood begins to circulate through the shunt, and the thrombus-coated thread is weighed.
