(57) **ABSTRACT**

Systems and methods for sorting electronic messages using attributes of senders or of sender addresses. An electronic messaging server sorts electronic messages using attributes associated with the senders or sender addresses of the electronic messages. The sender addresses and associated attributes are stored in an accept list. A sorting module uses the accept list to sort the electronic messages into various folders. The sorting module can also access other data sources, such as a contact list, to assist in sorting the electronic messages. The attributes can be determined independently of the user or can be set directly by the user. The attributes can also identify a status of a sender such as whether the sender is authorized, unauthorized, or unconfirmed.

SORTING ELECTRONIC MESSAGES USING ATTRIBUTES OF THE SENDER ADDRESS

CROSS-REFERENCE TO RELATED APPLICATIONS

This application is a continuation of Ser. No. 10/418,373, now U.S. Pat. No. 7,290,033, filed Apr. 18, 2003, which application is incorporated herein by reference in its entirety.

BACKGROUND OF THE INVENTION

1. The Field of the Invention

The present invention relates generally to sorting electronic messages. More specifically, the present invention relates to systems and methods for sorting incoming electronic messages using attributes associated with the sender, the sender address, and/or other characteristics of the electronic message.

2. Background and Relevant Art

Today, businesses and individuals are communicating using electronic messages such as emails, instant messages and voice messages. Communicating in this manner is convenient because the electronic messages are delivered relatively quickly to the recipient. Electronic messages enable individuals and businesses to carry on conversations, transact business, etc., at minimal cost. The ease by which a person is able to send and receive electronic messages thus makes this form of communication extremely attractive.

As a person or business begins to send and receive electronic messages, it quickly becomes clear that the electronic messages need to be sorted. The need to sort electronic messages, which often applies to both the electronic messages that are sent as well as to the electronic messages that are received, arises for a variety of reasons. First, many users have many different correspondents and these users can potentially receive hundreds of electronic messages over a short period of time. If a particular user is away from his or her computer for an extended period of time, sorting through unread messages can become a time consuming task. In fact, a user that does not check his or her email for a week or even a day is often faced with this problem. Thus, many users spend significant time sorting through the electronic messages that they have received.

The need to sort electronic messages is further complicated by unsolicited electronic messages. Unsolicited electronic messages typically include commercial advertisements and political messaging, but may also include offensive solicitations such as pornographic solicitations. Generally, users deal with both solicited and unsolicited messages on a daily basis. While many users tolerate sorting through solicited electronic messages, sorting through unsolicited electronic messages can be annoying and is a waste of valuable time.

Today, electronic messaging programs provide some sorting capabilities. Many of these methods, however, are dependent on actions of the user with respect to the electronic messaging program. The use of filter words, for example, to automate the process of sorting the electronic messages, is primarily applied to unsolicited electronic messages. In this case, a user enters certain words into a filtering system. When an electronic message having those certain words in the subject line or body of the message is received, the message can automatically be routed to a particular folder. This method requires a recipient to manually enter all of the filter words, specify which areas of the message are to be examined (i.e. the subject line, the body, etc.) and then direct the system where to send the messages. A clear disadvantage of this

method is that an electronic message can be easily placed in the wrong folder when an electronic message unexpectedly contains a filter term. When an electronic message is sent to the wrong folder, for example, the electronic message may be inadvertently deleted or the electronic message may not be read in a timely manner.

Some users sort their electronic messages manually. One of the problems faced by users in this situation is that the users are faced with the task of sorting through all of their electronic messages in order to identify and move certain electronic messages. In addition, some users may want to have a particular electronic message in more than one folder. When the electronic messages are sorted manually, those users are required to copy and paste the electronic message into each folder. Other users set up various rules that are applied to each electronic message. These rules are not related to persistent sender/sender addresses, but are typically applied to each electronic message to determine if the rule should apply. This can be computationally expensive.

Conventional techniques for sorting incoming electronic messages are dependent on the user and can often be cumbersome and difficult to manage. Because users receive increasing numbers of solicited and unsolicited electronic messages, there is a need to manage and sort electronic messages more effectively without having to apply a set of rules to each separate electronic message.

BRIEF SUMMARY OF THE INVENTION

These and other limitations are overcome by the present invention which relates generally to sorting electronic messages. The present invention further relates to systems and methods for sorting electronic messages using attributes associated with the sender, the sender address, and/or other aspects of the electronic message. One advantage of the present invention is that sorting the electronic messages is related to persistent senders and/or sender addresses. Thus, an electronic message can be sorted using attributes of a sender or sender address rather than applying a set of rules to each electronic message. In one embodiment, electronic messages are sorted using an accept list that stores sender addresses and the attributes of the sender addresses. The present invention can also be applied to instant messaging and other forms of addressable electronic messages including, but not limited to, voice mail messaging systems.

In one embodiment of the present invention, an accept list is created that stores sender addresses. Each sender address is associated with one or more attributes that are used to sort the electronic messages. The accept list, for example, includes attributes that identify whether a particular sender is authorized, unauthorized, or unconfirmed. The attributes also identify whether a particular sender has successfully responded to a challenge sent by the user's electronic message server. The attributes can also identify how a sender was included in the accept list. Other attributes can also be included in the accept list.

When an electronic message is received at an electronic message server, a sorting module sorts the electronic messages into particular folders using the attributes of the sender that are included in the accept list. If a sender or sender address is not included in the accept list, then the electronic message may still be sorted based on that fact. In one embodiment, the sender is entered in the accept list and assigned default attributes that are used to sort the electronic message.

One advantage of the present invention is that each electronic message does not have to be processed with rules that may or may not apply to the electronic message. In the present

invention, attributes are associated with sender addresses. Because the sender address is immediately known from the electronic message, the electronic message can be sorted using the attributes associated with the electronic message without first determining which rules apply to the electronic message.

The accept list, which stores sender addresses and their associated attributes, becomes a central data structure for an electronic messaging system that can provide stronger sorting capabilities. A sorting module can access not only the accept list to sort electronic messages, but can also take advantage of a user's contact list or other data structures to sort the electronic messages. In addition, the present invention can utilize a challenge/response to assist in automatically setting attributes in the accept list and in sorting the electronic messages. In this manner, electronic messages can be sorted without direct input from the user in one embodiment.

Additional features and advantages of the invention will be set forth in the description which follows, and in part will be obvious from the description, or may be learned by the practice of the invention. The features and advantages of the invention may be realized and obtained by means of the instruments and combinations particularly pointed out in the appended claims. These and other features of the present invention will become more fully apparent from the following description and appended claims, or may be learned by the practice of the invention as set forth hereinafter.

BRIEF DESCRIPTION OF THE DRAWINGS

In order to describe the manner in which the above-recited and other advantages and features of the invention can be obtained, a more particular description of the invention briefly described above will be rendered by reference to specific embodiments thereof which are illustrated in the appended drawings. Understanding that these drawings depict only typical embodiments of the invention and are not therefore to be considered to be limiting of its scope, the invention will be described and explained with additional specificity and detail through the use of the accompanying drawings in which:

FIG. 1 is a block diagram illustrating a generalized network through which an electronic message is transmitted from a sender computer to a user computer;

FIG. 2 is a block diagram depicting a generalized electronic messaging server that provides electronic messaging services including sorting services to various users;

FIG. 3A illustrates an accept list that associates attributes with a sender address;

FIG. 3B illustrates additional source attributes that indicate how a sender address was included in the accept list and that are associated with a sender address; and

FIG. 4 is a block diagram illustrating an electronic message that is sorted by a sorting module that uses the attributes associated with a sender address and/or a contact list of the intended recipient.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

The present invention relates to systems and methods for managing electronic messages. More particularly, the present invention relates to sorting electronic messages using attributes associated with the electronic message, the sender, and/or the sender address. The term "electronic messaging" includes any form of sending a message electronically including, but not limited to, via electronic mail (email), instant

messaging, voice messaging, telephonic messaging, and other forms of electronic communication that involve the use of a sender address and a recipient or user address. An electronic message includes, but is not limited to, emails, instant messages, attachments, voice mails, and the like or any combination thereof.

The following overview of electronic messaging is described in the context of email sent over the Internet. The term "unsolicited" as it relates to the invention refers to any electronic message that is not desired or wanted by the user. "Solicited" electronic messages refer to any electronic message that is desired or wanted by the user. Electronic messages from senders of bulk electronic messages can be solicited and/or unsolicited. Unsolicited electronic messages are typically sent from senders that are unauthorized.

FIG. 1 is a block diagram that illustrates an exemplary system for sending and delivering electronic messages over a computer network such as the Internet. In FIG. 1, a sender computer 10 sends an electronic message to a user computer 12. The electronic message is routed through one or more simple mail transfer protocol (SMTP) servers 14 before arriving at the electronic messaging server 15 associated with user computer 12. The electronic messaging server 15 may be a server residing on a local area network with user computer 12, a server that user computer 12 accesses via a modem pool or with another Internet connection, a web server that provides web-based electronic messaging services to user computer 12, or a server that operates with user computer 12 in any of a variety of other network configurations. The electronic messaging server 15 also represents a server or a system of servers that provide electronic messaging services to various user computers that are geographically dispersed. The present invention can be implemented on the electronic messaging server 15 or collapsed onto the user computer 12. When the present invention is implemented on the electronic messaging server 15, electronic messages are sorted for the users that subscribe or receive electronic messages through the electronic messaging server 15.

FIG. 2 illustrates an electronic messaging server 15 that provides electronic messaging services to the user computers 100, which are represented by the user computer 101 and the user computer 102. The electronic messaging server 15 has a mail application 16 that includes a sorting module 210 for sorting electronic messages. The mail application 16 operates for each of the user computers 100. The electronic messaging server 15 may also include other applications 17, such as a calendaring program, a contacts program, and the like. The mail application 16 is often integrated with the applications 17. The data storage device 19 may store data used by mail application 16 and applications 17.

In an alternative embodiment, the functionality of the mail application 16 and the sorting module 210 can be collapsed onto the user computers. If the user computer 101 is used by more than one person, the sorting module 210 of the mail application 16 also has the ability to sort electronic messages for all users of the user computer 101.

When an electronic message 38 arrives at the electronic messaging server 15, the mail application 16 processes the electronic message and the sorting module 210 sorts the electronic message 38. In one embodiment, the sorting module 210 uses an accept list that can be implemented on the electronic messaging server 15 or on the user computers 100. The accept list is usually a data structure that includes an entry for each sender address. In one embodiment, an accept list is maintained for each user computer. Each sender address in an accept list has various attributes that are used to sort electronic messages. In one embodiment, these attributes can be deter-

5

mined without direct input from the user while other attributes can be directly set by the user.

One advantage of having an accept list is that sorting electronic messages is related to sender addresses that are persistently stored by the electronic messaging server **15**. When an electronic message **38** is received by the electronic messaging server **15**, the attributes used to sort the electronic message can be immediately identified from the sender address of the electronic message. In contrast, a rule based system typically applies each rule to the electronic message in order to determine which rules apply. Thus, each electronic message is analyzed with respect to each rule, regardless of whether the rule actually applies to the electronic message. This inefficiency is overcome by the present invention because the attributes used to sort an electronic message are known from the sender address.

FIG. **3A** illustrates an exemplary embodiment of an accept list **18**. In this example, the accept list **18** is a data structure that includes sender addresses and the attributes that are associated with each sender address. The accept list **18** thus includes a sender address field **57** that stores sender addresses. The attributes **70** of the sender addresses include, but are not limited to, an authorized attribute **71**, an unauthorized attribute **72**, an unconfirmed attribute **73**, a workgroup attribute (illustrated in this embodiment as workgroup A **74** and workgroup B **75**), and a subject attribute **76**. One of skill in the art can appreciate that other attributes can also be included in the accept list.

The authorized attribute **71**, the unauthorized attribute **72** and the unconfirmed attribute **73** relate to whether a sender is permitted to send electronic messages to the user. The authorized attribute **71** of the sender address indicates that the sender is permitted to send electronic messages to the user and that electronic messages from that sender are not deleted or discarded. The unauthorized attribute **71** of the sender address indicates that the sender is not permitted to send electronic messages to the user and electronic messages from senders whose unauthorized attribute is set are not delivered to the user and may be deleted or stored in an unauthorized folder for later handling by the user.

The unconfirmed attribute **73** indicates that the sender is neither authorized or unauthorized. This may occur, for example, when an electronic message is received from a previously unknown sender. Electronic messages from an unconfirmed sender may be stored, for example, in a temporary folder. The user can voluntarily access this folder and access these electronic messages. Alternatively, these electronic messages are further sorted when the associated senders become either authorized or unauthorized senders of electronic messages.

FIG. **3B** illustrates additional attributes that may be included in the accept list **18**. The attributes in FIG. **3B** describe how a sender address was entered in the accept list **18** and are referred to herein as source attributes. These are examples of attributes that can be used to prioritize electronic messages as the electronic messages are sorted, although the attributes illustrated in FIG. **3A** can also be used to prioritize the electronic messages. For example, an electronic message from a sender that is explicitly authorized by the user may have a higher priority than electronic messages from senders that were not explicitly authorized.

Thus, a sender can become authorized or unauthorized in various manners and the attributes illustrated in FIG. **3B** describe a status of a particular sender as well as how a particular sender became either authorized or unauthorized. The user added attribute **242** indicates that, for example, a sender address **302** was explicitly added by the user to the

6

accept list **18**. The user added attribute **242** can therefore include sender addresses of senders that have not previously sent an electronic message to the user. The sent message attribute **244** indicates that the sender associated with the sender address **304** is authorized because the user sent an electronic message to that sender. By sending an electronic message to a sender, the user implies that the sender is an authorized sender and the sent message attribute **244** is set. In these example, the authorized attribute **71** of the corresponding senders is also set for authorized senders.

The challenge/response attribute **246** indicates the status of a sender with respect to a challenge that was sent to the sender. For instance, when a sender sends an electronic message to the user and the sender is neither an authorized sender nor an unauthorized sender, a challenge is sent to the sender by the electronic messaging server. At this point, the sender becomes an unconfirmed sender and the unconfirmed attribute of the sender is set in the accept list **18**. The sender is typically required to successfully respond to the challenge before the electronic message from the sender is delivered to the user. However, electronic messages from an unconfirmed sender may be delivered until the sender becomes unauthorized, which occurs if the sender does not successfully respond to the challenge. If the sender becomes an unauthorized sender, subsequent electronic messages are not delivered to the user.

The challenge, in one example, is an electronic message sent to the sender that includes a link to a web site. At the web site, the sender is required to enter a confirmation code in a text entry box provided at the web site. The confirmation code may be visible to the sender at the web site when the sender accesses the web site or may be included in the challenge. For example, a graphic that displays an alphanumeric code may be visible to a user at the web site. The user is required to enter the alphanumeric code in an entry box. Because the alphanumeric code is represented graphically, the code can typically only be entered by a person and cannot be entered automatically by a computer. Alternatively, the sender may be required to answer a question at the web site to successfully respond to the challenge. Only senders that successfully respond to the challenge can become authorized senders and have the authorized attribute set for their sender address. The challenge/response attribute **246** indicates whether the response was correct, whether the response was timely, and the like. The challenge/response attribute **246** can be related to the authorized attribute **71**, the unauthorized attribute **72**, and the unconfirmed attribute **73** in one embodiment.

The challenge issued by the mail application **16** is particularly useful against senders of unsolicited electronic messages. The challenge issued by the electronic messaging server is configured to permit a person to enter the correct response or confirmation code while preventing the correct response from being provided by a computer. Senders of unsolicited electronic messages typically generate automatic responses or no response at all and thereby become unauthorized senders because they fail to provide a correct response to the challenge.

In one embodiment of the accept list **18**, the attributes associated with a sender address can be established without direct input from the user. These attributes, even though they can be set independent of the user, can be changed or set by the user as well. For example, a sender can become an authorized sender by successfully responding to the challenge. A user, however, can set the unauthorized attribute of a sender even though the sender successfully responded to the challenge unsuccessfully.

The attributes of the sender addresses in the accept list **18** can further include attributes that are determined by the user. The workgroup attributes **74**, **75**, and the subject attribute **76** can be set by the user. The workgroup attributes are useful, for example, for directing electronic messages associated with particular workgroups. The workgroup attributes may indicate whether the sender is a partner, vendor, team-member, or other employee. These attributes can be used to sort electronic messages.

For example, an employee of a company may receive 200 electronic messages a day in the employee's inbox from authorized senders within the employee's company. The employee may also receive 50 electronic messages from authorized senders outside of the company. Using the accept list, the electronic messaging server can organize the electronic messages using the attributes associated with the senders of the electronic messages. The electronic messages may be sorted into folders based on the workgroup attributes, for example, or by other attributes in the accept list. Similarly, the subject attribute **76** may be used to sort electronic messages using the subject line of the electronic messages.

FIG. 4 illustrates an example of how an electronic message is sorted using attributes associated with the sender, sender address or other characteristic of the electronic message. In this example, an electronic message **38** has been received by an electronic messaging server and the attributes **70** have been accessed from the accept list based on the sender address of the electronic message **38**. The sorting module **210** applies the attributes **70** to sort or route the electronic message to the appropriate folder(s) or location(s). The sorting module **210** can route the electronic message to a particular folder **212** (such as an inbox) or to more than one folder such as to the folder **212** and the folder **214**. The sorting module **210** can also route an electronic message to a subfolder **216**. The folder **214**, for example, may be a temporary folder where electronic messages from unauthorized senders are sent. Alternatively, the folder **214** may be a work folder where electronic messages from coworkers in the same workgroup are placed.

The combination of attributes can determine where an electronic message is stored. For example, electronic messages can be given a high priority and stored in a priority folder. Electronic messages from senders that were explicitly entered in the accept list by the user may be given a higher priority than other electronic messages and placed in a particular folder. Electronic messages from authorized senders may be sent to the inbox folder while electronic messages from unconfirmed senders are held in a temporary folder until the senders are either authorized or unauthorized.

In another example, a user may subscribe to several newsletters, purchase goods on the Internet, and correspond with family members. The user thus receives electronic messages from each of these entities. In this example, all of the senders are authorized senders as the user desires to receive electronic messages sent by these entities. These senders also have other attributes that enable the sorting module to deliver electronic messages to corresponding folders. Family members, for example, may have a personal-private attribute that causes electronic messages from family members to be delivered to a family folder. Internet merchants may use a combination of a merchant attribute and an authorized sender attribute to deliver electronic messages to a merchant folder.

The sorting module **210** may also utilize a contact list **220** to sort the electronic messages. For example, all contacts in the user's contact list **220** can be deemed authorized senders and may be included in the accept list. When a contact is deleted, the contact simultaneously becomes an unauthorized sender or an unconfirmed sender and the corresponding attribute is set. The electronic messaging server has the ability

to scan the contact list automatically and make adjustments to the accept list based on the content of the contact list **220**.

The accept list **18** can also be used to associate attributes with domain names in addition to sender addresses. Electronic messages from senders in a particular domain can thus be sorted using the attributes associated with the domain. The accept list **18** may also be updated or refreshed periodically. This may give, for example, an unauthorized sender another opportunity to become an authorized sender. Alternatively, an authorized sender may also be required to again confirm that they are an authorized sender. This can be achieved in one embodiment by issuing a new challenge to the sender.

The embodiments of the present invention may comprise a special purpose or general-purpose computer including various computer hardware, as discussed in greater detail below. Embodiments within the scope of the present invention also include computer-readable media for carrying or having computer-executable instructions or data structures stored thereon. Such computer-readable media can be any available media that can be accessed by a general purpose or special purpose computer. By way of example, and not limitation, such computer-readable media can comprise RAM, ROM, EEPROM, CD-ROM or other optical disk storage, magnetic disk storage or other magnetic storage devices, or any other medium which can be used to carry or store desired program code means in the form of computer-executable instructions or data structures and which can be accessed by a general purpose or special purpose computer. When information is transferred or provided over a network or another communications connection (either hardwired, wireless, or a combination of hardwired or wireless) to a computer, the computer properly views the connection as a computer-readable medium. Thus, any such connection is properly termed a computer-readable medium. Combinations of the above should also be included within the scope of computer-readable media. Computer-executable instructions comprise, for example, instructions and data which cause a general purpose computer, special purpose computer, or special purpose processing device to perform a certain function or group of functions.

The following discussion are intended to provide a brief, general description of a suitable computing environment in which the invention may be implemented. Although not required, the invention will be described in the general context of computer-executable instructions, such as program modules, being executed by computers in network environments. Generally, program modules include routines, programs, objects, components, data structures, etc. that perform particular tasks or implement particular abstract data types. Computer-executable instructions, associated data structures, and program modules represent examples of the program code means for executing steps of the methods disclosed herein. The particular sequence of such executable instructions or associated data structures represents examples of corresponding acts for implementing the functions described in such steps.

Those skilled in the art will appreciate that the invention may be practiced in network computing environments with many types of computer system configurations, including personal computers, hand-held devices, multi-processor systems, microprocessor-based or programmable consumer electronics, network PCs, minicomputers, mainframe computers, and the like. The invention may also be practiced in distributed computing environments where tasks are performed by local and remote processing devices that are linked (either by hardwired links, wireless links, or by a combination of hardwired or wireless links) through a communications network. In a distributed computing environment, program modules may be located in both local and remote memory storage devices.

The present invention may be embodied in other specific forms without departing from its spirit or essential characteristics. The described embodiments are to be considered in all respects only as illustrative and not restrictive. The scope of the invention is, therefore, indicated by the appended claims rather than by the foregoing description. All changes which come within the meaning and range of equivalency of the claims are to be embraced within their scope.

What is claimed and desired to be secured by United States Letters Patent is:

1. In a system that includes an electronic messaging server that provides electronic messaging services to one or more users, a method for sorting electronic messages for a user, the method comprising:

for each sender that sends electronic messages to a user, assigning attributes to a sender address of each sender such that each sender address is associated with one or more attributes, wherein the sender addresses and the one or more attributes are stored in a first list, and wherein assigning the one or more attributes to the sender address does not require the one or more attributes to be user-defined;

receiving an electronic message from a particular sender at the electronic messaging server; and

sorting the electronic message into at least one folder based on the one or more attributes assigned to a particular sender address of the particular sender.

2. A method as defined in claim 1, wherein assigning attributes to a sender address of each sender such that each sender address is associated with one or more attributes further comprises:

setting an authorized attribute if the sender is authorized; setting an unauthorized attribute if the sender is unauthorized; and

setting an unconfirmed attribute if the sender is unconfirmed.

3. A method as defined in claim 1, wherein assigning attributes to a sender address of each sender such that each sender address is associated with one or more attributes further comprises issuing a challenge to the particular sender.

4. A method as defined in claim 3, further comprising:

receiving a response from the particular sender that received the challenge;

setting an authorized attribute for a sender address of the particular sender if the particular sender responds correctly to the challenge.

5. A method as defined in claim 4, further comprising setting an unauthorized attribute for the sender address of the particular sender if the particular senders does not respond to the challenges or responds incorrectly to the challenge.

6. A method as defined in claim 1, further comprising entering a sender address in the first list when an electronic message is sent to the sender address, wherein an authorized attribute of the sender address is set.

7. A method as defined in claim 1, further comprising associating one or more attributes in the first list with a domain.

8. A method as defined in claim 1, further comprising using a contact list of the user to assign the attributes in the first list.

9. A method as defined in claim 8, further comprising changing at least one attribute of a particular sender in the first list according to changes made to the particular sender in the contact list.

10. A method as defined in claim 8, further comprising at least one of

setting an unauthorized attribute of the particular sender if the particular sender is removed from the contact list; and

setting an authorized attribute of the particular sender if the particular sender is added to the contact list.

11. A method as defined in claim 1 wherein the first list is stored on at least one of a user computer or an electronic messaging server.

12. A computer program product comprising a computer usable medium having computer readable program code stored thereon, the computer readable program code having computer-executable instructions for performing the method of claim 1.

13. A system for sorting electronic messages of one or more users connected to the system comprising:

a persistent storage storing a first list comprising one or more senders of electronic messages sent to a first user and attributes associated with each sender;

computer readable program code having computer-executable instructions stored thereon that when executed by a processor, causes the system to perform the steps of:

determining a particular sender of an incoming message, accessing the first list stored on the persistent storage to determine the attributes of the particular sender, assigning an unconfirmed attribute to for the particular sender in the first list,

sorting the incoming message into an unconfirmed folder if the attributes of the particular sender indicate that the sender is neither authorized nor unauthorized, sending a challenge message to the particular sender, and

changing the unconfirmed attribute of the particular sender in the first list stored on the persistent storage depending on whether a reply message to the challenge message is received from the particular sender such that the user is not required to provide direct input to assign the unconfirmed attribute or change the unconfirmed attribute of the particular sender.

14. The system as defined in claim 13, wherein, when executed by a processor, the computer-executable instructions further causes the system to perform the steps of:

setting an authorized attribute of the sender address if the sender successfully responds to the challenge; and

setting an unauthorized attribute of the sender if the sender does not successfully respond to the challenge.

15. The system as defined in claim 13, wherein, when executed by a processor, the computer-executable instructions further causes the system to perform the step of assigning attributes of one or more senders in the first list using a contact list of the user.

16. The system as defined claim 15, wherein, when executed by a processor, the computer-executable instructions further causes the system to perform the steps of:

setting an unauthorized attribute for a particular sender address in the first list when the particular sender is removed from the contact list; and

setting an authorized attribute for a particular sender address in the first list when the particular sender is added to the contact list.

17. The system as defined in claim 13, wherein the persistent storage is located on at least one of a user computer or at an electronic messaging server.
