(57) **ABSTRACT**

A fan attachment is provided to attach a fan assembly to a cap of a heat exchanger. The fan attachment includes a feature to manage wires going to the fan motor, a notch for a thermister to sense temperature, snap hooks to be engaged by receiving tabs of the cap, a keying shear load feature to radially align the fan attachment and cap, and Z-height tolerance springs to bias the fan attachment away from the cap. The cap has features to interact with those of the fan attachment, including receiving tabs. The fan attachment may be manually aligned and forced so that the snap hooks are received and engaged by the receiving tabs. Additionally, the snap hooks and keying feature are, in combination, capable of supporting fan and attach mechanism in an undamaged condition during 25 g-force shock to the heat exchanger.

FAN ATTACHMENT APPARATUS FOR FAN
COMPONENT ASSEMBLIES

BACKGROUND

1. Field

One or more embodiments related generally to components and component assemblies for cooling electronic devices. More particularly, one or more embodiments relate to fan component assemblies, such as for attaching a fan assembly to a heat exchanger assembly of a computer.

2. Background

Electronic devices, such as computing devices, often require cooling of electronic circuitry, components, chips, disc drives, power transformers, and the like. Computing devices contemplated include personal computers (PC), desktop computers, computing systems, portable computing devices, handheld computing devices, telephones, cellular phones, game devices, Internet related computing devices, servers, televisions, video monitors or displays, digital video disk (DVD) players, set top boxes, as well as video storage and editing devices. In some cases, the computing device will have a main memory coupled to a processor, an operating system and other application programs to be executed by the processor.

For example, a printed circuit board (PCB), semiconductor chip package, semiconductor chip, power transformer, processor, central processing unit (CPU), memory chip, or other electronic device of a computer may be thermally coupled or attached to a heat exchanger that is cooled by a fan, such as by the fan blowing air onto the heat exchanger.

Typically, such fans are mounted independently of the heat exchanger or electronic device or devices they are to cool. For instance, a fan may have a cowling or external frame with holes running through the corners of the frame to allow the fan and frame to be attached to internal structure or the case of a computer. Specifically, current fans typically include a frame around the blade component, and a pattern of holes in the corners of the frame component to allow the fan to be fastened to the computer by putting mounting hardware, such as screws or other similar hardware through the holes and into the frame or internal structure of the computer.

However, such fan and frame assemblies require a frame for attachment to the computer; are not attached and/or proximate to a heat sink; and may not provide adequate cooling capacity or power, and thus may be unable to provide more than 100 watts of cooling.

BRIEF DESCRIPTION OF THE DRAWINGS

Various features, aspects and advantages will become more thoroughly apparent from the following detailed description, the set of claims, and accompanying drawings in which:

FIG. 1 is a side perspective view of a fan assembly attached to a cap of a heat exchanger by a fan attachment component.

FIG. 2 shows the fan assembly, cap, fan attachment, and heat exchanger of FIG. 1 prior to attachment of the fan attachment to the cap.

FIG. 3a is a top perspective view of a fan attachment.

FIG. 3b is a bottom perspective view of a fan attachment.

FIG. 4 is a side perspective view of fan assembly components, a fan attachment, a cap, and a heat exchanger prior to attachment of the fan attachment to the cap, showing snap hooks of the fan attachment and receiving tabs of the cap to receive and engage the snap hooks.

FIG. 5a is side perspective view of snap hooks of a fan attachment and receiving tabs of a cap.

2

FIG. 5b is another side perspective view of snap hooks of a fan attachment and receiving tabs of a cap.

FIG. 6a is a cross-sectional schematic view of a snap hook of a fan attachment and the receiving tab of a cap prior to the receiving tab receiving the snap hook.

FIG. 6b is a cross-sectional schematic view of a snap hook of a fan attachment and a receiving tab of a cap during the receiving tab receiving of the snap hook and prior to the receiving tab engaging the snap hook.

FIG. 6c is a cross-sectional schematic view of a snap hook of a fan attachment and a receiving tab of a cap after receiving tab receiving of the snap hook and during receiving tab engaging of the snap hook.

DETAILED DESCRIPTION

According to embodiments, a fan or a fan assembly may be attached to a heat sink or heat exchanger using a “fan attachment”. The fan attachment may be described as an apparatus or component of a system including a cap and/or heat exchanger apparatus or component. Specifically, the heat exchanger may be part of a heat exchanger assembly having a cap and the fan may be part of a fan assembly having a fan, where each assembly has various features, including features for alignment, receipt and engagement to couple or attach one assembly to the other assembly. For example, the fan attachment may include various features such as a wire management feature, a thermister notch, snap hooks, a keying shear load feature, Z-height tolerance springs, a receiving tab feature, and/or a keying feature. Also, the fan assembly (which may include the fan attachment) may exclude or not require a cowling or frame, such as for mounting the fan to internal structure or a frame of a computer, because the fan attachment provides sufficient mounting of the fan assembly to the heat exchanger. Moreover, the proximity and direct attachment or mounting of the fan assembly to the heat exchanger (e.g., such as by the fan attachment touching, engaging, or being directly attached or connected to a cap of the heat exchanger) allows for increased cooling. Specifically, using such an arrangement, the proximity of the location of the fan to the heat exchanger causes more of the air blown by the fan to go into the heat exchanger, than locating the fan farther from the heat exchanger. For instance, the proximity of the fan to the heat exchanger may be a factor contributing to the system of the exchanger and fan producing a higher performing heat exchange, such as producing cooling of equal to or greater than 100 watts of power. Also, the proximity of the fan to the heat exchanger may cause most (e.g., more than 50, 60, 70, 80, or 90 percent) of the air blown by the fan to go into the heat exchanger.

Reference in the specification to “embodiment”, “embodiments”, “one embodiment”, and “an embodiment” of the present invention means that a particular feature, component, structure, or characteristic described in connection with the embodiment is included in at least one embodiment of the present invention. Thus, the appearance of those phrases in various places throughout the specification are not necessarily all referring to the same embodiment. Moreover, in some cases, the fan attachment may be considered a component, a fan component, a part of a fan component assembly or fan assembly of an electronic device or computer to be attached to a heat exchanger, a component of a heat exchanger, or a cap of a heat exchanger of an electronic device or computer.

Also, directional references such as top, side, bottom, upper, lower, vertical, horizontal, outer, inner, above, below, beside, within, and the like may be relative terms, such as with regard to the disposition or orientation of various features or

component. Thus, such terms are not to be limiting, but are to provide an example of such orientations, positions, locations, and descriptions. For instance, although certain descriptions and drawing show the heat exchanger, cap, fan attach and fan (e.g., components of the system) in vertical alignment, such as disposed or mounted on a horizontal surface with respect to the surface of the Earth, it is also considered that the may be disposed or mounted on a surface other than horizontal, such as a vertical or angled surface. Thus, descriptions of up, down, top, bottom, vertical, horizontal and the like are relative terms and may have other meanings when the components of the system are mounted other than in vertical alignment.

FIG. 1 is a side perspective view of a fan assembly attached to a cap of a heat exchanger by a fan attachment component. FIG. 1 shows system 100 including fan assembly 110 attached to heat exchanger 160. Fan assembly 110 includes fan 120 and fan attachment 130. Heat exchanger 160 includes cap 170, such as to index with, attach to, and allow features to work together with a fan attachment or a fan assembly. Heat exchanger 160 may also include vanes 162 such as to provide increased cooling surface area for the fan to blow air upon to increase cooling capability of the heat exchanger 160 and fan assembly.

Fan attachment 130 is attached to cap 170, and vice versa, thus attaching fan assembly 110 to heat exchanger 160, and vice versa. Fan attachment 130 may also be described as attached to (and/or between) cap 170 of the heat exchanger and fan 120. For example, a number of snap hooks of fan attachment 130 may be engaged by a number of receiving tabs of cap 170 to secure, engage, attach, hold, or mount fan assembly 110 (e.g., fan attachment 130) to exchanger 160 (e.g., cap 170). Prior to such engaging, the snap hooks may be aligned with, mated with, or received by the receiving tabs. For instance, fan attachment 130 may be indexed, or aligned with cap 170 so that the snap hooks are aligned, mate with, or are received by receiving tabs of cap 170. Then, or during receiving of the snap hooks by the receiving tabs, upper portion UP of fan 120 may be pushed downwards towards exchanger 160 until the snap hooks are engaged, held, secured, attached, or mounted to the receiving tabs. Also, cap 170 may define a cylinder or cylindrical perimeter (or another perimeter matching the shape of perimeter 132) under the fan attachment.

Fan attachment 130 may be considered a component of fan assembly 110 and cap 170 may be considered a component of heat exchanger 160. Fan assembly 110 may include various other components, and components of fan assembly 110 may include various features. For example, fan assembly 110 may include a motor, a fan control (such as circuitry on a printed circuit board (PCB)) for controlling the speed of fan 120, a bearing to allow fan 120 to spin with respect to fan attachment 130, the motor, cap 170, and/or heat exchanger 160.

Similarly, heat exchanger 160 may include components other than cap 170 having various features. For example, heat exchanger 160 may be attached to, coupled to, thermally coupled to, or otherwise provide cooling for an electronic device, such as a chip package, semiconductor chip, and/or a processor. Specifically, a chip package may be mounted below heat exchanger 160 and thermally connected to heat exchanger 160 such as by thermally conductive epoxy, attachment, or contact between the heat exchanger and the package.

Heat exchanger 160 may be, or may be part of a heat exchanger assembly (e.g., an assembly having more components than shown or described herein). In some cases, heat exchanger 160 may provide liquid cooling, and/or be a liquid cooling heat exchanger. Thus, it can be appreciated that coolant lines may extend from heat exchanger 160 to be thermally

coupled to an electronic device, thus providing for cooling of the device. For instance, vanes 162 may be thermally coupled to a processor using a liquid coolant and/or a solid heat exchange material.

Fan 120 may be a cooling fan for moving or blowing air such as to spin in a counter-clockwise direction to blow air onto or into heat exchanger 160. Fan 120 may have a mass of between 50 and 100 grams, such as a mass of approximately 75, 80, 84, 86, 88, 90, 95 grams, or a mass in a range between any of those numbers. Although fan 120 is shown having five fan blades, it can be appreciated that fan 120 may include more or less than five blades, such as by having two, three, four, six, eight, or ten blades. Similarly, heat exchanger 160 is shown having a number of cooling vanes 162 extending radially away from cap 170 below fan 120, and for an axis running upwards through the center of heat exchanger 160. For instance, cap 170 may define or form a cylinder within heat exchanger 160, below fan attachment 130.

FIG. 1 shows fan assembly 110, fan 120, fan attachment 130, cap 170, and/or heat exchanger 160 in their expected use disposition or orientation. Specifically, fan attachment 130 is attaching assembly 110 to exchanger 160 such that fan 120 may rotate at a sufficient speed (e.g., rotational speed in a counter-clockwise direction) to blow a sufficient amount of air or move a sufficient amount of air onto, into, or through heat exchanger 160 to provide a desired amount of cooling. The desired amount of cooling may be providing cooling of 50, 60, 70, 80, 90, 100, 110, 120, 130, watts or a range between any of those numbers of watts of cooling. For example, an actual cooling capacity for the components of FIG. 1 may provide 130 watts of cooling, such cooling or cooling greater than that typically experienced by a fan arrangement, such as described in the background, may be increased since fan assembly 110 is attached to, proximate to, or separated only by distance D from the top of heat exchanger 160 (see also discussion of distance D in FIG. 4). Distance D may define a height or proximity between the bottom of the blades of fan 120 and the top of vanes 162 of exchanger 160.

FIG. 2 shows the fan assembly, cap, fan attachment, and heat exchanger of FIG. 1 prior to attachment of the fan attachment to the cap. FIG. 2 shows system 200 including fan assembly 110 prior to attachment of that assembly to heat exchanger 160. Thus, in FIG. 2, snap hooks of fan attachment 130 may not yet be received by or engaged by snap hooks of cap 170. FIG. 2 shows fan attachment 130 including outer perimeter 132 and snap hooks 140.

FIG. 2 also shows vanes 162 of exchanger 160. Heat exchanger 160 may have more or less vanes than that shown in FIG. 1 or 2. It is also considered that fan attachment 130 and/or cap 170 may be coupled to various other types of heat exchangers or electronic devices, such as where cap 170 is a component of, part of, or attached to a different type or shape of heat exchanger or electronic device.

Outer perimeter 132 may define or form an outermost perimeter surface, perimeter, or shape of fan attachment 130 (which may or may not exclude certain features of fan attachment 130, such as a wire management feature). Snap hooks 140 may represent a pair of snap hooks at two, three, four, five, six, or more locations around the perimeter of outer perimeter 132.

Cap 170 is shown having receiving tabs 180 formed on or in upper surface 172 of cap 170. Surface 172 may be described as a disc shaped surface (e.g., of a cylindrically shaped cap portion) that the tabs extend perpendicularly away from (e.g., up and away from the disc shaped surface). Although FIG. 2 shows four receiving tabs, it can be appre-

5

ciated that more or less receiving tabs, such as two, three, four, five, six, or more receiving tabs may be used. Specifically, a receiving tab may exist at upper surface **172** for each pair of snap hooks **140**. For instance, a receiving tab may be located on cap **170** at a location of (or a location “corresponding” to) a location of each pair of snap hooks, such as to receive and engage each pair of snap hooks once properly indexed (e.g., by keying and shear load **370**, keying feature **475**, and or surfaces of the snap hooks and tabs as described herein).

For instance, outer perimeter **132** may define a cylinder, oval, circular, square, polyhedron, or other perimeter surface or shape having arms ending in snap hooks to be received and engaged by receiving tabs **180**. The majority of the outer surface of perimeter **132** may be flat and/or have texture. The majority of the outer surface of perimeter **132** may have a cross sectional shape that is or is not vertically planar. In some cases, the outer surface of perimeter **132** may form the outside of a cylindrical shape broken only by the snap hooks, slots and other features of fan attachment **132** described herein. Alternatively, the outer surface of perimeter **132** may also be broken by other features not mentioned herein.

FIG. **2** also shows arrows **210** that may represent the direction, force, and/or pressure for attaching fan attachment **130** to cap **170**. For example, arrows **210** may represent manual force MF shown being applied to upper portion UP of fan **120** in order to have snap hooks **140** received by and engaged by receiving tabs **180**. Manual force MF may be a force of between 2 and 3.7 pounds of pressure on upper portion UP, such as by being 2.0, 2.2, 2.4, 2.6, 2.8, 3.0, 3.2, 3.4, 3.6, 3.7, or a range between any of those numbers of pounds of pressure applied to upper portion UP. For example, manual force, MF may be created by a person, machine, or robot pressing on upper portion UP. Similarly, arrows **210** may represent a force as described above for manual force MF, such as where the force is generated other than at upper portion UP of fan **120**. Thus, arrows **210** may represent a force capable of being generated by a person, such as the force with which snap hooks **140** are pressed towards receiving tabs **180** such as to be received by and engaged by receiving tabs **180**.

It is considered that attachment of assembly **110** or fan attachment **130** to exchanger **160** or cap **170** may be described by receiving and/or engagement of snap hooks **140** by receiving tabs **180**. In some cases, such attachment may also include lifting or biasing of the fan attachment away from the cap by springs, such as will be described later.

FIG. **3a** is a top perspective view of a fan attachment. FIG. **3b** is a bottom perspective view of a fan attachment. FIG. **3a** and **3b** show fan attachment **130** having generally disk shape **301** around center axis **302**, top surface **303** and bottom surface **304**. Radially distal from axis **302** is outer perimeter **132**, such as a ring shaped outer perimeter, having a number or arms, such as arm **135** of the outer perimeter surface. One or more of arms **135** may define openings **134** in or through the disk shape between axis **302** and outer perimeter **132** (e.g., between axis **302** and arms **135**). It may also be said that outer perimeter **132** or an inner ring surface of arms **135** may define openings **134**, where the openings exist. Arms **135**, ends **335** of arm **135**, and/or portions of outer perimeter **132** may define or be separated by slot **342** through the outer perimeter surface and to an opening of openings **134**. Specifically, adjacent ends **335** of adjacent arms **135** may define a slots through outer perimeter surface **132** and to opening **134**. Pairs of adjacent snap hooks **140** are on the outer perimeter surface, where each snap hook has wedge shape **136** pointing from top surface **303** towards bottom surface **302** and extends radially outwards from outer perimeter surface **132** on either side of

6

the slot. Fan attachment **130** also includes wire management feature **320**, thermister keep out notch **310**, pairs of snap hooks **140**, keying and shear load **370**, and Z-height tolerance springs **380**.

FIGS. **3a** and **3b** also show thermister keep out notch **310** defined by surfaces of fan attach **130** and having a geometry and/or surfaces to provide an opening, location or clearance for locating or mounting a thermister component for sensing the ambient air around the fan. The thermister component can be electrically (e.g., using wires) attached to the fan motor or fan motor control PCB to provide feedback or temperature data sensed for the ambient air around the fan so that a fan speed (e.g., revolutions per minute (RPM)) may be select or set to provide sufficient cooling or a sufficient amount of air into exchanger **160**. It can be appreciated that although surfaces defining notch **310** are shown defining a rectangular notch, various other shapes and sizes may be used, as long as the shape and size is sufficient for receiving and retaining a thermister (e.g., such as a shape equal to a x-section of the thermister).

Wire management feature **320** includes or defines openings **322** and **325** such as to route power and control wires from a fan motor of a fan coupled to the fan attachment (or a fan motor PCB for controlling the fan) to a power header for plugging into a power source. Thus, feature **320**, surfaces defining opening **322** and/or opening **325** may prevent the wires from contacting blades of the fan as they rotate, such as by providing or defining openings to route the wires out of the fan assembly, under the fan blades, and/or into the heat exchanger.

FIGS. **3a** and **3b** also show snap hooks **140** each having wedge shape **136**, and opening **134** behind outer perimeter **132** where snap hooks **140** are located at or on perimeter **132**. Snap hooks **140** may be described as having wedge shape **136** located on, pointing down along, and/or extending outwards from outer perimeter surface **132** (e.g., at locations at which snap hooks are located on perimeter **132**). Each of the snap hooks of the pair may be described as pairs of adjacent snap hooks on either side of a slot or opening through or dividing arms **135** along or of perimeter **132**. Thus, in addition to being defined by other structures such as arms, arm ends, and the out perimeter surface, a slot may also be defined by adjacent snap hooks. FIGS. **3a** and **3b** show four pair for a total of eight snap hooks, although other numbers of pairs greater or less than four pair are considered.

The snap hooks may be described as mounted or located on perimeter **132** (e.g., as a wedge shape pointing down) at the end of arms **135**. A snap hook may be described as a wedge shape pointing down along perimeter **132** at the end of arm **135**. Arm **135** may be an arm of fan attachment **130** defined by or part of perimeter **132**. Also, arm **135** may define perimeter **132**, opening **134** and the slot separating the snap hook from the adjacent snap hook (and the end of the adjacent arm). Arm **135** may be sufficiently flexible so a force or pressure on the snap hook (e.g., such as inwards towards the axis or center of the fan attachment) causes the arm to flex or move back (e.g., at the end of the arm where the snap hook is) into opening **134**. The arm flexing or moving back may include or also be described by saying that the snap hook flexes or moves back, and vice versa.

FIGS. **3a** and **3b** also show keying and shear load **370** defining gap **372** to properly align fan attachment **130**, with an index or a protrusion of cap **170** having receiving tabs **180**. For instance, surfaces defining gap **372** may be used to index or properly align fan attachment **130**, radially, with an index

or a protrusion of cap 170 so that snap hooks of fan attachment 130 are properly align, radially, with receiving tabs of cap 170.

FIGS. 3a and 3b also show Z-height tolerance springs 380, such as springs having a sufficient spring force “k” to keep fan attachment 130, fan assembly 110, and/or components thereof from rattling or reduce an amount of rattling caused by clearances between cap 170 and fan attachment 130. Keeping from rattling or reducing rattling can be accomplished or caused by the springs, collectively, forcing, pressing, or lifting fan attachment 130 away, up, and/or vertically away from receiving tabs 180, to hold surfaces, such as top surfaces, of snap hooks 140 against a top inner surface of the receiving tabs. Thus, the collective force may be sufficient to ensure that a fan coupled to fan attachment 130 is at a known position relative to the heat exchanger (e.g., in three dimensional location, with respect to the “yaw” axis or rotational axis of the fan), such as to have the bottom of blades of the fan at a known distance D (see FIG. 1) in height above the top surfaces of vanes of the heat exchanger. It can be appreciated that the springs can perform a similar function for keeping the blades above structures, electronic devices, or other cooling components in addition to a heat exchanger, such as when a heat exchanger is not used. It can be appreciated that although springs 380 are shown having four springs, various numbers of springs, such as two, three, five, six, eight, or more springs may be used, as long as the springs provide a similar force for performing the functions described above.

FIG. 4 is a side perspective view of fan assembly components, a fan attachment, a cap, and a heat exchanger prior to attachment of the fan attachment to the cap, showing snap hooks of the fan attachment and receiving tabs of the cap to receive and engage the snap hooks. FIG. 4 shows system 400 including components of fan assembly 110 and heat exchanger 160. Specifically, motor 410, bearing 420, thermister component 430, fan motor control PCB 440, and fan attachment 130 of fan assembly 110 are shown. Similarly, cap 170 of heat exchanger 160 is shown. FIG. 4 also shows features of fan attachment 130 including outer perimeter 132, opening 134, thermister notch 310, snap hooks 140, slot 342, and wire management feature 320. Slot 342 may represent a slot between, separating, or dividing a pair of snap hooks, such that each snap hook or wedge shape of each snap hook may point down along and extend outwards from perimeter 132 on either side of slot 342.

Also, as shown in FIG. 4, surfaces defining thermister notch 310 may have a geometry, size and surfaces to provide clearances for thermister component 430, which may be attached to or part of PCB 440 for sensing the ambient air (e.g., a temperature of the air) around the fan so that the circuitry of PCB 440 can set or change the fan speed to provide sufficient cooling to heat exchanger 160.

As shown in FIG. 4, management feature 320 may include or define openings to mount wires from motor 410 and/or PCB 440 to a power header (not shown). Although feature 320 is shown having a curved shape, surfaces defining two openings at openings 322, and surfaces defining one opening for opening 325, it can be appreciated that various other shapes, surfaces defining openings, and/or numbers of openings may be used for feature 320. Moreover, feature 320 may include structures to fix and/or restrain the wires, such as wherein the openings are smaller, include rubber, or other structure to hold or restrain a wire from being pulled one direction or another through feature 320.

Motor 410 may be a motor that rotates with fan 120 or rotates a shaft attached to fan 120. Motor 410 may be a motor for spinning a fan with sufficient speed, or RPMs, to provide

cooling as described herein. Bearing 420 may be a bearing for rotating fan 120. PCB 440 may be a PCB including circuitry, logic, and/or control circuitry to control the speed of rotation of fan 120 as described herein. Also, thermister component 430 may be a thermister to fit within surfaces defining thermister notch 310 and may provide sufficient feedback or signal of the ambient air around fan 120 to allow PCB 440 to adjust the speed of the fan to provide sufficient cooling. Specifically, the rotational speed of the fan may be increased to provide additional cooling (e.g., increase a rate of cooling of exchanger 160) when the ambient temperature around the fan exceeds a high temperature threshold; and/or decreased to reduce cooling (e.g., decrease a rate of cooling of exchanger 160) when the ambient temperature around the fan is below a low temperature threshold.

As shown in FIG. 4, gap 372 defined by surfaces of keying and shear load feature 370 may align fan attachment 130 with cap 170. The surfaces defining gap 372 may align with or index protrusion 477 defined by surfaces of keying feature index 475 of cap 170. It can be appreciated that although keying and shear load 370 is shown defining gap 372 with a certain size and shape, various sizes and shapes for gap 372 may be used as long as they are sufficient for being indexed by an index or protrusion. In some cases, although protrusion 477 is shown having a curved shape, it can be appreciated that protrusion 477 can have various shapes and/or sizes as appropriate for indexing or being engaged by surfaces of keying and shear load 370 that define gap 372. Specifically, feature 370, surfaces defining gap 372, index 475 and/or protrusion 477 may have surfaces, shape, size, and/or material sufficient to index fan attachment 130 during receiving and engaging of snap hooks 140 by receiving tabs 180 to resist rotation and/or provide shear resistance for fan attachment 130 with respect to cap 170. For instance, engagement of protrusion 477 and surfaces defining gap 372 (e.g., during or while snap hooks engage index tabs) may prohibit rotation and/or provide shear resistance for fan attachment 130 with respect to cap 170 during rotation of fan 120, such as during use of fan 120, during or as a result of a 20 g-30 g shock (e.g., such as from an impact in any direction, to a computer case or motherboard on which the heat exchanger is mounted), without damaging material and/or surfaces defining gap 372 and/or protrusion 477.

Also, snap hooks 140 may have a wedge shape and/or surfaces to be received by and engaged by openings defined by receiving tabs 180 so that the snap hooks snap-in or spring-snap into the receiving tabs and/or engaged by the receiving tabs to resist rotation and provide shear resistance for the fan attachment during rotation of the fan. For instance, the snap hooks may be snap-in type hooks or spring snap type hooks to snapped into opening of the receiving tabs (e.g., into surfaces defining the openings) to maintain attachment of the fan to the heat sink.

Also, the indexing by feature 370 and index 475, and/or engagement of snap hooks 140 by receiving tabs 180 may provide sufficient resistance of rotation, shear resistance, indexing, engagement of snap hooks by receiving tabs, and/or attachment of fan attachment 130 by cap 170 to retain or maintain indexing, engagement and/or attachment during a shock to an electronic device, motherboard, system board, PCB, casing, outer surfaces, or inner structure of an electronic or computer device to which heat exchanger 160 and/or cap 170 are coupled, attached, or mounted (e.g., such as being firmly and directly connected to transfer the shock). Specifically, the indexing, engagement, and/or attachment may be sufficient to be retained or maintained during a 20 g (e.g., a “G” force or force of the acceleration of the Earths gravity

upon an object near the surface of the Earth, which is considered one “g”), 25 g, 30 g, 35 g, or a g-forces shock in a range between any of those numbers in any direction to the electronic device, system board, or computer to which cap 170 is coupled. This the indexing, engagement, and/or attachment of the snap hooks and keying feature, in combination, may be capable of supporting fan and attach mechanism in an undamaged condition during 25 g-force shock to the heat exchanger. Similarly, the indexing, engagement, and/or attachment may be sufficient to be retained or maintained while providing cooling as described herein. The receiving and engagement of snap hooks by receiving tabs is described further below.

FIG. 4 also shows Z-height tolerance springs 380 to keep from rattling or reduce rattling of fan attachment 130, bearing 420, motor 410, thermister component 430, PCB 440, and/or feature 320 by lifting fan attachment 130 away from receiving tabs 180, surface 172, and/or cap 170 (e.g., biasing the fan attachment away from the receiving tabs so that surfaces 546 engage surfaces 594 of FIG. 5). Specifically, FIG. 4 shows distance D1 as the height of outer perimeter 132 of fan attachment 130. In some cases distance D may equal distance D1. It can be appreciated that distance D may be a higher less than or great than the height of perimeter 132. For instance, distance D may be a height of 1, 2, 3, 8, 10, 20, 40, 80 millimeters (mm), or any combination of thereof or range between any combination of thereof above a top surface of exchanger 160 and/or upper surface 172. Thus, distance D may correspond to the distance between the bottom of the blades of the fan and the top of the heat exchanger 160 and/or vanes 162. As such, in embodiment, springs 380 bias or force fan attachment 130 away from surface 172 such that an upper surface of snap hooks 140 is biased against and inner upper surface of receiving tabs 180 to keep the bottom of the fan blades a height equal to distance D above vanes of heat exchanger 160.

Z-height tolerance springs 380 may have a shape and size, and a material sufficient to bias fan attachment 130 during receiving and engaging of snap hooks 140 by receiving tabs 180 to maintain distance D, such as by resisting reduction of distance D of fan attachment 130 with respect to cap 170. For instance, the force provided by Z-height tolerance springs 380 (e.g., during or while snap hooks engage index tabs) may properly bias fan attachment 130 so that the blades maintain distance D above the top of the exchanger (e.g., vanes) during rotation of fan 120, such as during use of fan 120, during or as a result of a 20 g-30 g forces shock, without damaging the material of Z-height tolerance springs 380.

FIG. 5a is side perspective view of snap hooks of a fan attachment and receiving tabs of a cap. FIG. 5b is another side perspective view of snap hooks of a fan attachment and receiving tabs of a cap. FIGS. 5a and 5b show features, geometry, and surfaces of snap hooks 140 of fan attachment 130; and of receiving tabs 180 of cap 170. Specifically, FIGS. 5a and 5b show fan attachment 130 including outer perimeter surface 132 having vertical slot 342, and pairs of adjacent snap hooks 140 each having wedge shape 136 pointing downwards along and extending outwards from outer perimeter surface 132 on either side of slot 342. Each wedge may be described as located on surface 132 adjacent to or beside slot 342. Also, each pair of adjacent snap hooks may be received by opening 590 and engaged by the surfaces of receiving tab 180 that define opening 590. For example, each pair of snap hooks may have a number of surfaces to be received by and engaged by a number of inner perimeter surfaces that define opening 590. In some cases, the snap hooks or wedge shapes may be defined by the surfaces to be received and engaged.

Similarly, openings 590 may be defined by tabs 180 and/or surfaces of tabs 180 to receive and engage surfaces of hooks 140.

In more detail, FIGS. 5a and 5b show each snap hook 140 or wedge shape 136 having top surface 546, outside side surface 548, inside side surface 550 and lower surface 544. Top surface 546 may be parallel (or approximately parallel, such as within 5 degrees of parallel) to top surface 303 of disc shape 301 of the fan attachment. Outside side surface 548 may be perpendicular (or approximately perpendicular, such as within 5 degrees of perpendicular) to top surface 303 and/or to outer perimeter surface 132. Inside side surface 550 may also be perpendicular (or approximately perpendicular, such as within 5 degrees of perpendicular) to top surface 303 and/or to outer perimeter surface 132. Additional descriptions for the surfaces include that lower surface 544 may be described as angled away from outer perimeter surface 132 (e.g. away from the lower edge of surface 132), and may define a rectangular, square, and/or flat surface extending from the edge or surface of surface 132 along an outer edge of the outside side surface 548 and inside side surface 550 to an outer edge of top surface 546. Correspondingly, top surface 546 may be described as disposed away from cap 170 or surface 172 and extending perpendicular to outer perimeter surface 132. Top surface 546 may define a rectangular, square, and/or flat top surface between the upper edges of the outside side surface 548, the inside side surface 550 and the upper edge of the lower surface 544. Outside side surface 548 and inside side surface 550 may be disposed vertically and extend perpendicular to outer perimeter surface 132. For instance, surface 548 and/or surface 550 may define a triangular and/or flat vertical surface between surface 132, an edge of top surface 546, and an edge of lower surface 544. Inside side surfaces 550 may be described as facing or dispose toward each other and/or slot 342 and may form a planar surface extending into and including inner surface 444 of slot 342 (see FIG. 5b).

Correspondingly, receiving tab 180 may include or define inner surfaces 592, bottom inner surface 596, and top inner surface 594. Surfaces 592 may be for receiving, engaging and/or restraining surfaces 548. Bottom inner surface 596 may be for receiving, engaging and/or restraining surfaces 544. Also, top inner surface 594 may be for receiving, engaging and/or restraining surfaces 546. Inner surfaces 592, bottom inner surface 596, and top inner surface 594 may be said to define opening 590.

Receiving tab 180 may also include or define front surface 582, outer top surface 587, outer side surfaces 586, upper surface 584, and back surface 583. Inner surfaces 592 may define a rectangular, square, and/or flat top surface between surface 582 and 583 along an edge of surface 594 and 596. Top inner surfaces 594 and/or bottom inner surface 596 may define a rectangular, square, and/or flat top surface between surface 582 and 583 along an edge of surfaces 592. Surface 596 may be the same surface 172. Front surface 582 and back surface 583 may also be said to define opening 590.

Inner surfaces of or defining opening 590 may be described as corresponding to or matched to surfaces of snap hooks 140. For instance, surface 548 may correspond to surface 544 during indexing and receiving of hooks 140 by tab 180. Also, surfaces 592 and/or surface 594 may correspond to surfaces 548 and/or surface 544, respectively, during indexing, receiving, and engagement of hooks 140 by tab 180.

Upper surface 584 may be angled, cambered, and/or have a shape corresponding to surface 544 to cause hook 140 to be indexed, received, and/or engaged by tab 180 as described herein (e.g., see FIG. 6a-6C). Surface 587 may be optional, as

11

upper surface **584** may extend from back surface **583** to an edge of front surface **582**. Alternatively, surface **587** may exist, such as to define or select an angle, chamber or chamber of surface of **584** with respect to surface **544** of fan attachment **130**. Specifically, lower surface **544** may be angled away from the surface of perimeter **132** to cause the orientation, disposition or angle of surface **544** and surface **584** (e.g. a plane defined by the surfaces) to match, correspond, be parallel, or be equal. Moreover, the angle may be selected or angled away such that the first contact between surface **544** and surface **584**, during proper receiving, indexing, or alignment creates a contact area of a plane, a line, or a point as designed or selected.

Thus, hook **140** (e.g., the end of arm **135** having the hook) and tab **180** may flex away from each other during receiving and then upon disposition of hook **140** within opening **590** may flex back towards each other so that surface **546** engages surface **594**, thus defining engagement of hook **140** by tab **180**. It can be appreciated that such engagement may include where surface **594** is matched to, corresponds to, is parallel to, or defines a contact shape of a plane or a line with surface **546**.

Similarly, one or both surface(s) **548** may be indexed, oriented or restrained by one or both surface(s) **592** during receiving and then upon disposition of hook **140** within opening **590** so that surface(s) **548** engage surface(s) **592**, thus also defining engagement of hook **140** by tab **180**. It can be appreciated that such engagement may include where surface(s) **592** are matched to, correspond to, are parallel to, or define a contact shape with surface(s) **548**, such as a plane or a line of contact between surface **592** and **548**.

FIG. **6a** is a cross-sectional schematic view of a snap hook of a fan attachment and the receiving tab of a cap prior to the receiving tab receiving the snap hook. FIG. **6a** shows arm **135** of fan attachment **130** having snap hook **140** at a location of outer perimeter **132**. Snap hook **140** is shown having top surface **546** and lower surface **544**. FIG. **6a** also shows cap **170** having receiving tab **180** having upper surface **584**, and top inner surface **594** of opening **590**. It is considered that FIG. **6a** may represent a pair of adjacent snap hooks (e.g., in profile so that only one is showing) of the receiving tab of a cap prior to the receiving tab receiving the snap hook.

It can be appreciated that various surface shapes, textures and angles for upper surface **584** and/or surface **544** can be used or selected to provide indexing, receiving, and/or engaging as described herein. For example, angle **A1** of surface **544** from vertical surface of perimeter **132** and angle **A2** of surface **584** a horizontal plane can be selected to be complimentary (e.g., to add up to 90 degrees). Alternatively, angle **A1** and **A2** may in a range of between 5 to 10 degrees from complimentary. Also, angle **A1** can be an angle between 30 degrees and 60 degrees. Angle **A1** or **A2** can be an angle of 35, 40, 45, 50, 55 degrees, or in a range between any of those two numbers in degrees.

FIG. **6b** is a cross-sectional schematic view of a snap hook of a fan attachment and a receiving tab of a cap during the receiving tab receiving of the snap hook and prior to the receiving tab engaging the snap hook. FIG. **6b** shows receiving tab **180** receiving snap hook **140** such as where contact between surface **544** and **584** defines a contact shape of a plane, a line, or a point. For example, first contact between surfaces **544** and **584** may define a contact shape of a plane or a line. It is considered that FIG. **6b** may represent a pair of adjacent snap hooks (e.g., in profile so that only one is showing) of the receiving tab of a cap during the receiving tab receiving the snap hook and prior to the receiving tab engaging the snap hook.

12

Then, as manual force **MF** (e.g., see description with respect to FIGS. **1** and **2**) forces surface **544** farther down with respect to surface **584**, hook **140** (e.g., the end of arm **135** having the hook) and tab **180** may flex away from each other, such as to create a contact shape of a line or point. For example, arm force **AF** is shown representing the contact force or pressure of hook **140** (e.g., the end of arm **135** having the hook) and tab **180** against each other in the radial direction (e.g., such as inwards, perpendicular to, towards the axis or center of the fan attachment by the tab and away from that axis for the hook) that results from manual force **MF** during receiving. Force **AF** may cause arm **135** to flex away or move back (e.g., at the end of the arm where the snap hook is) into opening **134**. Force **AF** may be described as two equal force components, in opposite directions (e.g., at a point of contact between hook **140** and tab **180**). Thus, in some cases, saying the snap hook flexes and the arm flexes may be synonymous.

Specifically, FIG. **6b** shows flexing **FR** as a distance that back surface **583** flexes outward from surface **132**. Likewise, FIG. **6b** shows flexing **FS** as a total distance that surface **132** flexes away from surface **583**. In other words, flexing **FR** may describe a distance that tab **180** flexes away from hook **140**, and flexing **FS** may describe a distance that hook **140** (e.g., the end of arm **135** having the hook) flexes away from tab **180** due to a force between the hook and the tab at contact shape **610** (e.g., a point or a line of contact). Flexing **FR** and **FS** may be described as two equal flexing distances, in opposite directions (e.g., at a point of contact between hook **140** and tab **180**). Force **AF** may be caused by the a shape, size, and/or material of arm **135** and/or tab **180** resisting flexing **FR** and **FS**, where flexing **FR** and **FS** is caused by manual force **MF** and/or the shape, angle and/or size of hook **140**, surface **544**, surface **584**, and/or tab **180**. For a pair of snap hooks, **FR** and **FS** may be the same for each snap hook, however **AF** required will be double for the pair of snap hooks.

According to embodiments, arm **135**, hooks **140**, and/or tab **180** may be designed (e.g., have a shape, size, and/or material sufficient) to flex during alignment, receiving (e.g., caused by a manual force) and engaging so that after flexing during receiving, the arm **135**, hooks **140**, and/or tab **180** can “unflex” or return to its original shape without becoming damaged or permanently deformed (e.g., be able to return to within one to 10 percent of its original profile, as shown in FIGS. **6a-6c**).

FIG. **6c** is a cross-sectional schematic view of a snap hook of a fan attachment and a receiving tab of a cap after receiving tab receiving of the snap hook and during receiving tab engaging of the snap hook. FIG. **6c** shows hook **140** engaged by tab **180**, surfaces of tab **180** and/or defining opening **590**. It is considered that FIG. **6c** may represent a pair of adjacent snap hooks (e.g., in profile so that only one is showing) of a fan attachment and a receiving tab of a cap after receiving tab receiving of the snap hook and during receiving tab engaging of the snap hook. Specifically, FIG. **6c** may represent locating a pair of snap hooks within or between the plurality of corresponding surfaces defining opening **590** of the receiving tab.

As compared to FIG. **6b**, the hook and tab may have flexed back towards each other (e.g., the components of force **AF**, flexing **FR**, and/or flexing **FS** are now zero or substantially zero). As compared to FIG. **6a**, the hook and tab in FIG. **6c** may not be flexed at all. For example, surface **132** may be adjacent to, touching, abutted against, and/or parallel to surface **583**. Also, flex **FR** and/or flex **FS** (e.g., flexing of arm **135**) may be described as being zero in FIG. **6c**. Hook **140** being engaged by tab **180** may also include one or both of surfaces **592** of opening **590** engaging corresponding one or

both of surfaces **548** of hook **140**, such as to resist rotation and/or provide shear resistance of fan attachment **130** with respect to cap **170**.

Also, the engagement may include surface **594** engaging surface **546** and/or surface **592** engaging surface **548**, such as to prohibit disengagement or detachment of hook **140** from tab **180** or opening **590**. This engagement may prohibit disengagement without components becoming damaged, during use (e.g., during rotation of the fan at a speed sufficient to provide cooling), and/or as a result of a 20 g-30 g shock (e.g., a physical shock having a force of between 20 and 30 g-forces to the heat sink). Also, one surface engaging another may be described by the surface being adjacent to or touching, being restrained by, being maintained by, or not moving beyond the other surface.

In other words, the engagement may describe a pair of hooks **140** being secured at a pair of outside side surfaces **548** by a pair of side inner surfaces **592**, and/or top surface **546** secured by or engaged by top inner surface **594**, such that a pair of snap hooks are restricted from, unable to, or otherwise prohibited from rotating, lifting off of, becoming detached from, or leaving surfaces defining opening **590** without damage, breaking, or bending of snap hooks **140** and/or receiving tab **180**. This relationship may also be described as the hooks, a geometry of the hooks, and/or surfaces of the hooks being engaged by the tab, surfaces defining the opening of the tab, and/or the geometry of those surfaces of the tab with sufficient resistance to prohibit disassembly, detachment or disengagement without damaging, breaking or bending the hooks or tab (e.g., at least one hook or tab must be damaged to detach the fan assembly from the cap).

Similarly the engagement may include a pair of hooks **140** being secured at a pair of outside side surfaces **548** by a pair of side inner surfaces **592**, and/or top surface **546** secured by or engaged by top inner surface **594**, such that a pair of snap hooks are restricted from, unable to, or otherwise prohibited from rotating, lifting off of, becoming detached from, or leaving tab **180**, or surfaces defining opening **590** during use, such as during rotation of the fan for cooling. This relationship may also be described as the hooks, a geometry of the hooks, and/or surfaces of the hooks being engaged by the tab, surfaces defining the opening of the tab, and/or the geometry of those surfaces of the tab with sufficient resistance during use, such as during rotation of the fan for cooling, to prohibit disassembly, detachment or disengagement.

Likewise, the engagement may include a pair of hooks **140** being secured at a pair of outside side surfaces **548** by a pair of side inner surfaces **592**, and/or top surface **546** secured by or engaged by top inner surface **594**, such that a pair of snap hooks are restricted from, unable to, or otherwise prohibited from rotating, lifting off of, becoming detached from, or leaving opening **590** during or as a result of a 20 g-30 g shock. This relationship may also be described as the hooks, a geometry of the hooks, and/or surfaces of the hooks being engaged by the tab, surfaces defining the opening of the tab, and/or the geometry of those surfaces of the tab with sufficient resistance during or as a result of a 20 g-30 g shock, to prohibit disassembly, detachment or disengagement.

The snap hooks, arms, and/or receiving tabs may have a shape, size, and/or material sufficient to provide the indexing, receiving (e.g., flexing) and/or engagement described herein between the snap hooks and receiving tabs (e.g., between the fan attachment and cap). In some cases, the engagement above includes a resistive force (e.g., similar to force AF during receiving) caused by a shape, size, and/or material (e.g., without damaging the material) of arm **135** and/or tab **180** resisting flexing (e.g., similar to resisting flexing FR and

FS). This flexing resistance may be in response to or during a manual force to the fan assembly, heat exchanger, components thereof, rotation of fan **120** (e.g., during use of fan **120**), a 20 g-30 g shock. Also, this flexing resistance may be caused by or a result of the material, shape, surfaces, angles of surfaces (e.g., of surface **544** and/or surface **584**) and/or size of hook **140** and/or tab **180**.

For instance, materials included in the snap hooks, arms, and receiving tabs may be plastic, metal, semiconductor, organic material, inorganic material, and polymers. Similarly, materials included may be materials that meet the stated generic material type: Polybutylene Terephthalate (PBT). Materials included may have the following material properties: tensile yield strength 120 megapascals (MPa); percent elongation at break $\geq 4\%$; Flexural modulus ≥ 7000 MPa; and/or heat deflection (HDT) ≥ 109 degrees Celsius. The material may comprise a thermoplastic polybutylene terephthalate (PBT) twenty percent through thirty percent nylon glass filled (GF) or equivalent, or an equivalent material having critical mechanical material properties including tensile yield strength greater than 120 MPa, percent elongation at break greater than or equal to four percent, flexural modulus greater than or equal to 7,000 MPa and less than equal to 9,800 MPa.

According to some embodiments, edge **620** of hook **140** may not extend out to front surface **582** of tab **180** (e.g., as shown in FIG. **6c**). In some cases, edge **620** may not extend radially beyond surface **582** (e.g., surface **546** may be shorter or extend radially outward less distance than surface **594**). Alternatively, edge **620** may extend radially beyond surface **582**.

It can also be appreciated that spacing tolerances between surfaces, assemblies, features and/or components described above may be included in the systems without detracting from the concepts above. For instance, spacing tolerances, may provide spacing between surfaces of pair of hooks **140** and tabs **180** defining opening **590**, such as tolerances to allow for receiving of the hooks by the surfaces defining the opening and engagement of the hooks by the surfaces defining the opening. Specifically, FIG. **6c** shows a small gap between surface **594** and surface **596**. This gap may be sufficient or necessary for the hook to be properly received and snapped into the surfaces defining opening **590** to provide engagement (e.g., snapped engaged by the receiving tabs). Similarly, the snap hooks and receiving tabs may be designed (e.g., have a shape, size, and/or material sufficient) so that the snap hooks “over travel” when transitioning from being received to being engaged by the surfaces defining the opening. Likewise, concepts described herein consider part tolerances and geometry not being perfect, such as deviations from manufacturing that are known and/or tolerated.

Similarly, it is considered that the descriptions herein for fan attachment **130**, cap **170**, receiving tab **180**, snap hook **140**, features and components thereof may be used to attach a fan to various other machines, devices, surfaces, components, and the like for cooling or blowing air, whether or not the cooling or blowing air is for an electronic device. For example, the heat exchanger may be optional, as often the fan is used to directly cool or blow on the electronic device without blowing on the heat exchanger. Thus, the fan attachment and/or fan assembly may blow air onto or be thermally coupled to an electronic device, such as a chip package, semiconductor chip, and/or a processor. In this instance, the features of the heat exchanger assembly may exist on a device that does not have a heat exchanger.

In the foregoing specification, specific embodiments are described. However, various modifications and changes may

15

be made thereto without departing from the broader spirit and scope of embodiments as set forth in the claims. The specification and drawings are, accordingly, to be regarded in an illustrative rather than a restrictive sense.

What is claimed is:

1. A fan attachment comprising:

a generally disc shape having a top surface, a bottom surface, and a ring shaped outer perimeter surface having arms, the arms defining a plurality of openings through the disc shape between the outer perimeter surface and a center axis of the disc shape, the arms having ends defining a plurality of slots through the outer perimeter surface and to the openings;

a plurality of pairs of adjacent snap hooks on the outer perimeter surface, each snap hook having a wedge shape pointing from the top surface towards the bottom surface and extending radially outwards from the outer perimeter surface on either side of a slot.

2. The fan attachment of claim 1, wherein each wedge shape includes a top surface parallel to the top surface of the disc shape, an outside side surface perpendicular to the top surface of the disc shape, an inside side surface perpendicular to the top surface of the disc shape, and a lower surface extending from the outer perimeter surface to the top horizontal surface.

3. The fan attachment of claim 2, wherein the inside side surface of each snap hook faces an inside side surface of another snap hook, and the lower surface extends between the outside side surface and the inside side surface of each snap hook.

4. A system comprising:

a fan attachment having a top surface, a bottom surface, a ring shaped outer perimeter surface having arms, and a plurality of pairs of adjacent snap hooks on the outer perimeter surface and extending radially outwards from the outer perimeter surface on either side of a slot, the arms defining a plurality of openings through the disc shape between the outer perimeter surface and a center axis of the disc shape, the arms having ends defining a plurality of slots through the outer perimeter surface and to the openings through the disc shape;

a heat exchanger having a cap, the cap including a plurality of receiving tabs, wherein each pair of adjacent snap hooks has a plurality of surfaces to be received by and engaged by a plurality of corresponding surfaces defining an opening of a receiving tab.

5. The system of claim 4, wherein each snap hook further comprises:

a lower surface angled away from the outer perimeter surface to cause an upper surface of the receiving tab to flex away from the snap hook when the snap hook is being received by the corresponding surfaces;

a top surface disposed away from the heat exchanger and extending perpendicular to the outer perimeter surface to engage a corresponding top inner surface defining the opening of the receiving tab;

an outside side surface disposed perpendicular to the outer perimeter surface to engage corresponding a side inner surface defining the opening of the receiving tab.

6. The system of claim 4, wherein the snap hooks are on the ends of the arms, the receiving tabs are on an upper surface of the cap, and the receiving tabs and arms comprise a material having a flexibility to allow the arms to return to an original shape after receipt and during engagement of the snap hooks by the receiving tabs.

16

7. The system of claim 4, wherein:

the fan attachment is attached to the cap of the heat exchanger and is attached to a fan,

the top inner surface is adjacent to the top surface, and

the side inner surface is adjacent to the outside side surface during one of rotation of the fan at a speed sufficient to provide cooling and a physical shock having a force of between 20 and 30 g-forces to the heat sink.

8. The system of claim 4, wherein each receiving tab comprises a generally rectangular shape extending perpendicular and away from the an upper surface of the cap at a location corresponding to a location of the snap hooks, the a rectangular shape having a front surface, a back surface, outer surfaces and inner surfaces defining the opening of the receiving tab.

9. The system of claim 4, wherein the receiving tabs comprise:

an angled upper surface to cause angled lower surfaces of a pair of snap hooks to flex away from the receiving tabs when the snap hook is being received by the receiving tab;

a top inner surface to engage top surfaces of a pair of snap hooks when the snap hook is engaged by the plurality of corresponding surfaces defining an opening of a receiving tab; and

a pair of side inner surface to engage outside side surfaces of a pair of snap hooks when the snap hook is engaged by the plurality of corresponding surfaces defining an opening of a receiving tab.

10. The system of claim 4 wherein the fan attachment is coupled to a motor and through bearings to a fan, wherein the receiving tabs and snap hooks are disposed between the heat exchanger and the fan, and wherein the fan attachment is disposed between a cap of the heat exchanger and the fan.

11. The system of claim 4 wherein the heat exchanger includes a plurality of vanes extending radially away from the cap below the fan, the vanes thermally coupled to a processor, the thermal coupling including one of a liquid coolant and a solid heat exchange material, wherein the cap defines a cylinder under the fan attachment.

12. The system of claim 11 wherein the receiving tabs extend upward from the cap, away from the cap and vanes at radial positions around a top surface of the cap, the snap hooks extend radially outward from an outer radial surface of the fan attachment, and each pair of snap hooks are received and engaged by the plurality of corresponding surfaces defining an opening of a receiving tab.

13. The system of claim 1 wherein the fan attachment further comprises a keying and shear load feature to align the fan attachment with an index of a cap having the receiving tabs.

14. The system of claim 13 wherein the keying and shear load feature indexes the fan attachment during receiving of the fan attachment by the cap and resist rotation and provides shear resistance for the fan attachment during rotation of the fan.

15. The system of claim 1 wherein the snap hooks are snap-in type hooks or spring snap type hooks snapped into the plurality of corresponding surfaces defining an opening of the receiving tabs to maintain attachment between the fan attachment and the receiving tab during a 30 g shock to a system board that the receiving tabs are coupled to.

16. The system of claim 15 wherein the receiving tabs are part of a cap coupled to a heat exchanger; and wherein the fan attachment further comprises:

a wire management feature to route power and control wires from a fan motor of a fan coupled to the fan

17

attachment to a power header for plugging into a power source, and to prevent the wires from contacting blades of the fan as they rotate;
a thermister notch having a geometry to provide clearance to a thermister component attached to a fan motor control printed circuit board (PCB) for sensing a temperature of ambient air around the fan;

18

Z-height tolerance springs to lifting the fan attachment away from the receiving tabs to hold the snap hooks against a top inner surface of the receiving tabs.
