(57) ABSTRACT

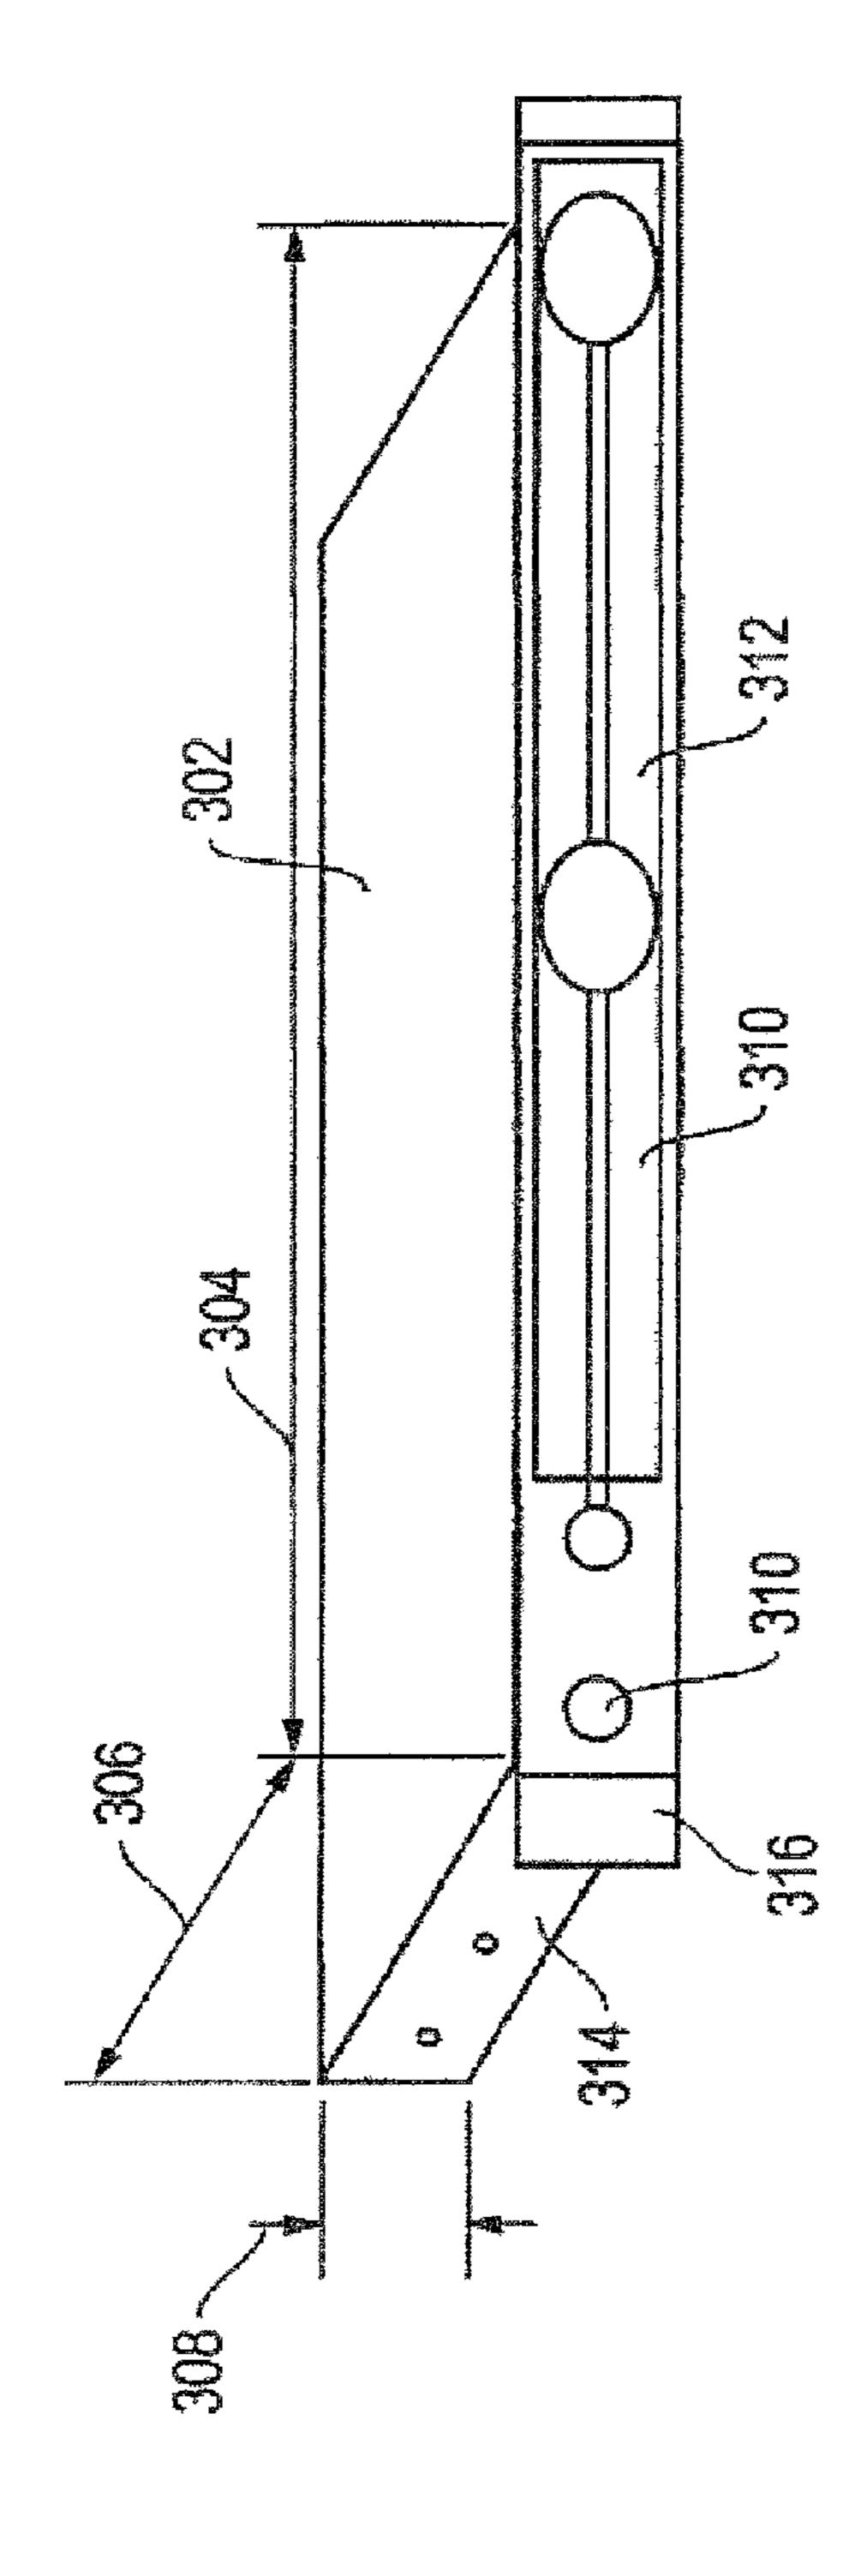

Methods and devices for routing communications between distributed mobile architecture (DMA) servers using DMA gateways are disclosed. Communications information is received at a first DMA gateway for a communications network accessible by a second DMA gateway. The communications information indicates one or more devices that are accessible by one of a DMA server and a legacy communications network. The first DMA gateway and the second DMA gateway participate in a DMA gateway communications network. The communications information is stored in a home DMA register of the first DMA gateway. A communication is received at the first DMA gateway for a target device indicated by the communications information to be served by the second DMA gateway. The communication is routed from the first DMA gateway to the target device by relaying the communication from the first DMA gateway to the second DMA gateway via the DMA gateway communications network.

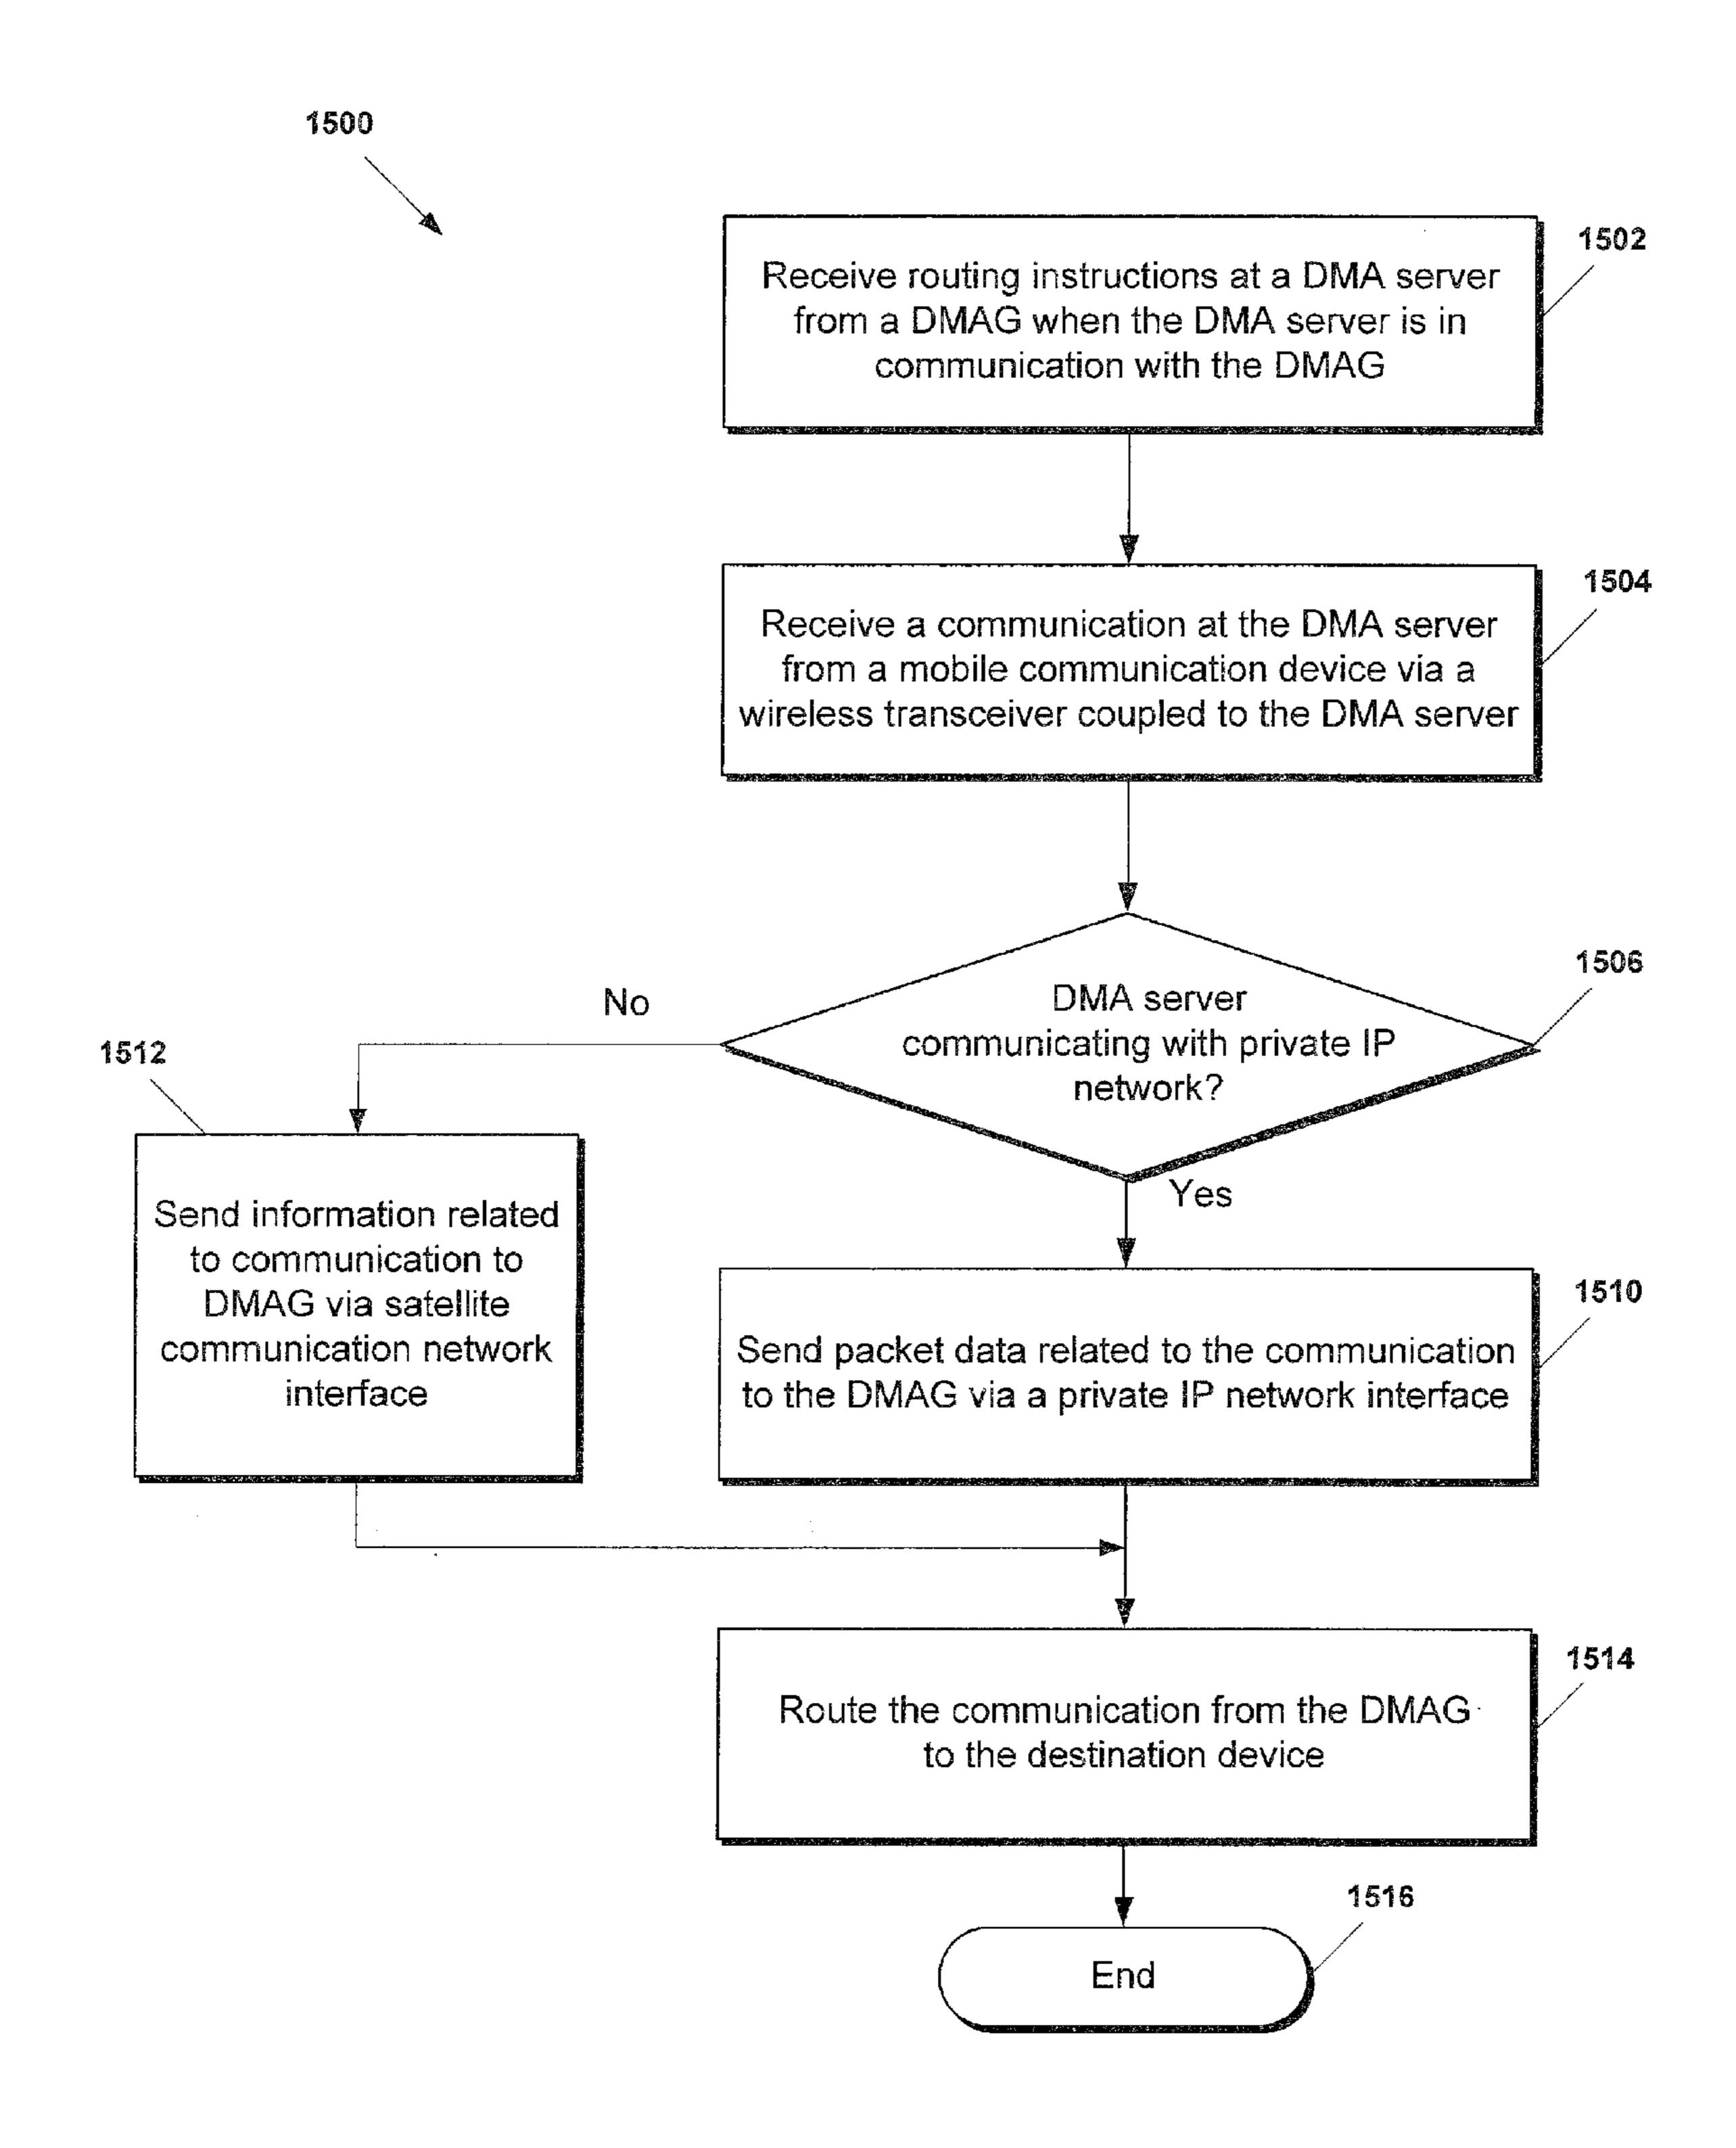

FIG. 15

SYSTEM, METHOD, AND DEVICE FOR ROUTING CALLS USING A DISTRIBUTED MOBILE ARCHITECTURE

FIELD OF THE DISCLOSURE

The present disclosure relates generally to distributed mobile communications systems.

BACKGROUND

Access to basic telephony service is particularly important for rural and isolated communities. Telephony access allows small-scale enterprises, cooperatives, and farmers to obtain accurate information on fair prices for their products and to access regional and national markets. Access also reduces the cost of transportation and supports the local tourist industry. By bringing markets to people via telecommunications, 20 rather than forcing people to leave in search of markets, urban migration is reduced and greater income and employment potential are generated in rural areas.

Unfortunately, the last decade of the telecommunications boom has not alleviated the disparities between urban and rural communities. The average imbalance, in terms of telephone penetration, in Asia, for example, is over ten to one and is often as high as twenty to one. This means that a country whose urban markets have a penetration of four (4) telephone $_{30}$ lines per one-hundred (100) inhabitants, e.g., India and Pakistan, has a rural penetration of less than 0.2 per one-hundred (100). The situation is more acute in most African countries and in some parts of Latin America. By comparison, the disparity in average income level between urban and rural 35 of a network incorporating a plurality of satellite-based and residents in the developing world is usually less than 4 to 1.

Current telephone systems are expensive to deploy. For example, a typical cellular system that includes a mobile switching center (MSC), a base station controller (BSC), and a home location register/visitor location register (HLR/VLR) can cost over \$2.0 million. Moreover, such a system may require a minimum of ten thousand users in order to be economically viable. In many rural areas, the population is not large enough to support the installation of such a system. 45 Further, in many cases, the conditions in which the equipment (e.g., the MSC, BSC, and HLR/VLR) are to be operated are extremely harsh and environmentally prohibitive. An alternative to such a cellular system can include a wired system, but the costs associated with deploying and maintaining land lines are too high for certain rural areas.

In deploying telephone systems in such situations, a further concern is how to expand an existing telephone system or implement a new phone system capable of operating with existing telephone systems. For example, it may be desirable 55 to allow communications with users serviced by existing public switched telephone network (PSTN) services, Voice over Internet Protocol (VoIP) systems, wireless communications systems, and other systems. Providing compatibility between these systems presents a challenge in itself. Moreover, because some of these systems may be deployed in rural or other remote areas, providing a medium through which newly deployed systems can communicate with one another presents a concern.

Accordingly, there exists a need for an improved communications system that is relatively inexpensive to deploy and

relatively inexpensive to operate, as well as able to integrate different communications systems.

BRIEF DESCRIPTION OF THE DRAWINGS

The present invention is pointed out with particularity in the appended claims. However, other features are described in the following detailed description in conjunction with the accompanying drawings in which:

FIG. 1 is a view of a particular illustrative embodiment of a distributed mobile architecture (DMA) server having a first illustrative form factor;

FIG. 2 is a view of another particular illustrative embodiment of an alternative embodiment of a DMA server having a 15 second illustrative form factor;

FIG. 3 is a diagram of another particular illustrative embodiment of an alternative embodiment of a DMA server having a third illustrative form factor;

FIG. 4 is a diagram of a particular illustrative embodiment of a distributed and associative communications system;

FIG. 5 is a block diagram of a particular illustrative embodiment of a DMA server;

FIG. 6 is a diagram of a particular illustrative embodiment of a network incorporating a plurality of DMA gateways 25 linking a plurality of DMA servers and a legacy network;

FIG. 7 is a diagram of a particular illustrative embodiment of a network incorporating a plurality of satellite-based DMA gateways linking a plurality of DMA servers and a legacy network;

FIG. 8 is a diagram of a particular illustrative embodiment of a network incorporating a DMA gateway linking a plurality of satellite-based DMA servers and ground-based DMA servers;

FIG. 9 is a diagram of a particular illustrative embodiment ground-based DMA gateways linking a plurality of satellitebased and ground-based DMA servers;

FIG. 10 is a diagram of a particular illustrative embodiment of a network incorporating a plurality of DMA gateways and a plurality of legacy networks utilizing a central register database for communications devices accessible within the network;

FIG. 11 is a block diagram of a particular illustrative embodiment of a DMA gateway;

FIG. 12 is a diagram of a particular illustrative embodiment of an exemplary data structure used by a DMA gateway for maintaining information about communications devices accessible through other gateways;

FIG. 13 is a diagram of a particular illustrative embodiment of an exemplary structure maintained in a central database accessible by DMA gateways to maintain information about communications devices accessible throughout a network;

FIG. 14 is a flow chart to illustrate a particular illustrative embodiment of the use of information about accessible networks and devices for routing communications between DMA gateways; and

FIG. 15 is a flow chart to illustrate a particular illustrative embodiment of a selective routing of a communication by a DMA gateway via a private Internet Protocol network or a 60 gateway network.

DETAILED DESCRIPTION OF THE DRAWINGS

Methods and devices for routing communications between 65 distributed mobile architecture (DMA) servers using DMA gateways are disclosed. Communications information is received at a first DMA gateway for a communications net-

work accessible by a second DMA gateway. The communications information indicates one or more devices that are accessible by one of a DMA server and a legacy communications network. The first DMA gateway and the second DMA gateway participate in a DMA gateway communications network. The communications information is stored in a home DMA register of the first DMA gateway. A communication is received at the first DMA gateway for a target device indicated by the communications information to be served by the second DMA gateway. The communication is routed from 10 the first DMA gateway to the target device by relaying the communication from the first DMA gateway to the second DMA gateway via the DMA gateway communications network.

In a particular embodiment, a first distributed mobile architecture (DMA) gateway includes a number of interfaces. A first interface is adapted to communicate with a legacy communications network. A second interface is adapted to communicate with a private Internet Protocol (IP) network. A third interface is adapted to communicate with a DMA gate- 20 way communications network. The gateway also includes a server having logic adapted to receive legacy network information from a second DMA gateway, the legacy network information indicating that the legacy communications network is in a communications range of the second DMA gateway. The DMA gateway forwards information associated with a communication received from a DMA server via the second interface to the second DMA gateway via the third interface. The call is placed to a destination device accessible via the legacy communications network.

In another particular embodiment, first routing instructions at a first distributed mobile architecture (DMA) server from a first DMA gateway when the first DMA server is in a first service area of the first DMA gateway. The first DMA gateway comprises a first orbiting satellite. A first call received at the first DMA server from a first mobile communications device via a wireless transceiver integrated with the first DMA server is sent to the first DMA gateway via a private Internet Protocol (IP) network according to the first routing 40 instructions. The first call is placed to a destination device accessible via a legacy communications network, the legacy communications network accessible via the first DMA gateway.

In another embodiment, a distributed mobile architecture 45 (DMA) server is coupled to a wireless transceiver. The DMA server includes a first interface adapted to communicate with a private Internet Protocol (IP) network and a second interface adapted to communicate with a satellite communications network. The DMA server includes a server having logic adapted to receive a call from a mobile communications device via the wireless transceiver and send call information related to the call to a DMA gateway. The DMA gateway comprises an orbiting satellite. The call is placed to a destination device accessible via a legacy communications network, the legacy communications network accessible via the DMA gateway.

In yet another embodiment, an orbiting satellite includes a first interface adapted to communicate with a legacy communications network and a second interface adapted to communicate with a private Internet Protocol (IP) network. The 60 protect the display 134, the keyboard 116, the mouse 118, and satellite also includes a server having logic adapted to receive a call via the first interface. The call is placed to a first mobile communications device accessible to a first distributed mobile architecture (DMA) server. The call is then routed to the first DMA server via the second interface, wherein the first 65 DMA server includes a wireless transceiver to communicate with the first mobile communications device.

According to the present disclosure, one or more of the communications devices between which a communication, such as a voice communication and/or a data communication, participates in a communications network via a DMA server. A DMA server enables the deployment or expansion of a communications network to, for example, rural areas where remoteness of the area to be served or a relatively small customer base to be served make the installation of a conventional telephone system impractical or otherwise undesirable. As further described below according to embodiments of this disclosure, while one or more DMA servers may communicate with one another over a private IP network, when a private IP network is not available, the DMA servers may communicate through a plurality of DMA gateways that communicate with one another through a gateway communications network. For example, the DMA gateways may be implemented as orbiting satellites that participate in a gateway communications network that includes a satellite communications network.

In introducing the operation of DMA gateways, exemplary embodiments of DMA servers and their operation are described below.

Referring to FIG. 1, a DMA server is shown and is generally designated 100. As illustrated in FIG. 1, the DMA server 100 includes a base 102 and a lid 104. As shown, the lid 104 is attached to the base by a first lid hinge 106 and a second lid hinge 108. In a particular embodiment, the lid 104 can be rotated about the first lid hinge 106 and the second lid hinge 108 between an open position, shown in FIG. 1, and a closed position (not shown) in which the lid **104** overlays the base 102 and the DMA server 100 is essentially shaped like a box or a briefcase.

As indicated in FIG. 1, the base 102 has a length 110, a width 112 and a height 114. FIG. 1 shows that the DMA server 100 includes a keyboard input device 116 that is incorporated in an upper surface of the base 102. Further, the DMA server 100 includes a mouse input device 118 that is also incorporated into the upper surface of the base 102. In a particular embodiment, the mouse input device 118 is a touch mouse input device 118. Additionally, the DMA server 100 includes a left side button 120 and a right side button 122. In a particular embodiment, the left side button 120 can be used to perform left-click functionality associated with the mouse input device 118. Moreover, the right side button 122 can be used to perform right-click functionality associated with the mouse input device 118.

FIG. 1 further indicates that the base 102 of the DMA server 100 is formed with a vent 124 to permit air exchange with the interior of the base 102 of the DMA server 100 and to facilitate cooling of the electronic components of the DMA server 100 housed within the base 102. Moreover, the base 102 of the DMA server 100 includes a handle 126 that is attached to the base 102 via a first handle hinge 128 and a second handle hinge 130. The base 102 also includes a pair of latch engagement notches 132.

As shown in FIG. 1, the lid 104 includes a flat panel display 134 incorporated therein. When the lid 104 is closed, the display 134 is adjacent to the keyboard 116. Moreover, when the lid 104 is closed, the lid 104 and the base 102 cooperate to the buttons 120, 122. FIG. 1 also depicts a latch 136 that is incorporated into the lid 104. When the lid 104 is closed, the latch 136 can engage the latch engagement notches 132 in order to lock the lid in the closed position. As depicted in FIG. 1, an antenna 138 is incorporated into the lid 104. The antenna 138 can be extended during operation and retracted when the DMA server 100 is not operating.

In a particular embodiment, the length 110 of the base 102 is 31.0 centimeters. Further, in a particular embodiment, the width 112 of the base 102 is 25.5 centimeters. Additionally, in a particular embodiment, the height 114 of the base 102 with the lid 104 in the closed position is 7.0 centimeters. Accordingly, the DMA server 100 has a total volume of 5,533.5 centimeters cubed and a footprint area of 790.5 centimeters squared. Further, in a particular embodiment, the DMA server 100 weighs approximately 5.8 kilograms (kg). As such, in a particular embodiment, the DMA server 100 has a total volume that is less than 6,000 centimeters cubed, a footprint area that is less than 800 centimeters squared, and a weight that is less than 6.0 kilograms.

In a particular embodiment, the DMA server 100 is relatively rugged. Particularly, the DMA server 100 is operable in a temperature range from negative twenty degrees Celsius to positive fifty-five degrees Celsius (-20° C. to 55° C.). Also, the DMA server 100 is substantially shock resistant and can withstand a one meter drop. Further, the DMA server 100 is substantially weather resistant, substantially dust resistant, and substantially sand resistant. The DMA server 100 is portable and it can be mounted in a vehicle or carried like a brief case. Further, multiple DMA servers 100 can be deployed as described herein.

FIG. 2 depicts an alternative embodiment of a distributed mobile architecture (DMA) server that is generally designated 200. As shown in FIG. 2, the DMA server 200 includes a base 202 and a lid 204 that is coupled to the base 202 via a plurality of fasteners (not shown). Additionally, the DMA server 200 has a length 208, a width 210, and a height 212. Further, the base 202 of the DMA server 200 includes a first vent 214, a second vent 216, and a third vent 218. In a particular embodiment, the vents 214, 216, 218 permit air exchange with the interior of the base 202 of the DMA server 200 and facilitate cooling of the electronic components of the DMA server 200 housed within the base 202. As shown in FIG. 2, the DMA server 200 includes an access window 220. One or more interfaces 222, e.g., wires can be accessed via the access window 220 and coupled to a base transceiver station 40 (BTS) during deployment of the DMA server **200**. As shown in FIG. 2, the DMA server 200 can be mounted within a vehicle 224. Further, multiple DMA servers 200 can be deployed as described herein.

In a particular embodiment, the length **208** of the base **202** is 92.0 centimeters. Further, in a particular embodiment, the width **210** of the base **202** is 45.0 centimeters. Additionally, in a particular embodiment, the height **212** of the base **202** is 34.0 centimeters. Accordingly, the DMA server **200** has a total volume of approximately 140,760 centimeters cubed and a footprint area of approximately 4,140 centimeters squared. Further, in a particular embodiment, the DMA server **200** weighs approximately 48 kilograms (kg). As such, in a particular embodiment, the DMA server **100** has a total volume that is less than 150,000 centimeters cubed, a footprint area that is less than 5,000 centimeters squared, and a weight that is less than 50.0 kilograms.

FIG. 3 illustrates another alternative embodiment of a distributed mobile architecture (DMA) server that is generally designated 300. As depicted in FIG. 3, the DMA server 300 60 includes a housing 302 that has a length 304, a width 306, and a height 308. Additionally, the housing 302 can be formed with a first vent 310 and a second vent 312. In a particular embodiment, the vents 310, 312 permit air exchange with the interior of the housing 302 of the DMA server 300 and facilitate cooling of the electronic components of the DMA server 300 within the housing 302.

6

As shown in FIG. 3, at least one side of the housing 302 is formed with a rib 314 to enable the DMA server 300 to be slid into a server rack (not shown). Further, the DMA server 300 includes a clip 316 that is coupled to the housing 302 via a fastener, e.g., a bolt. The clip 316 can be engaged with a server rack (not shown) to prevent the DMA server 300 from unintentionally sliding out of the server rack (not shown).

In a particular embodiment, the length **304** of the housing 302 is approximately 76.2 centimeters. Further, in a particular embodiment, the width 306 of the housing 302 is approximately 48.2 centimeters. Additionally, in a particular embodiment, the height 308 of the housing 302 is approximately 4.3 centimeters. Accordingly, the DMA server 300 has a total volume of approximately 15,756.5 centimeters cubed and a footprint area of approximately 3,672.9 centimeters squared. Further, in a particular embodiment, the DMA server 300 weighs approximately 17.7 kilograms (kg). Also, in a particular embodiment, the DMA server 300 is stackable in order to support various capacity requirements. As such, in a particular embodiment, the DMA server 100 has a total volume that is less than 16,000 centimeters cubed, a footprint area that is less than 4,000 centimeters squared, and a weight that is less than 20.0 kilograms.

The description of embodiments of DMA servers with reference to FIGS. 1-3 are provided for illustration, not limitation. DMA servers also may be embodied in any other suitable form. For example, as described further below, a DMA server may be incorporated within an orbiting satellite that communicates with DMA gateways and other devices via satellite and ground-based communication networks.

FIG. 4 illustrates a non-limiting, exemplary embodiment of a distributive and associated telecommunications system generally designated 400. As depicted in FIG. 4, the system 400 includes four cellular coverage sites 402. Each coverage site 402 includes an antenna 404. In one embodiment, the antenna 404 is connected to a transceiver belonging to a base transceiver station (BTS) and the BTS is a 3-sector BTS. FIG. 4 also indicates that a distributed mobile architecture (DMA) server 406 (abbreviated in FIG. 4 and figures as "DMAS") can be connected to each antenna 404. In one embodiment, each DMA server 406 is physically and directly connected to its respective antenna 404, e.g., by a wire or cable 408. Further, in an illustrative embodiment, the DMA servers 406 can be any of the DMA servers shown in FIG. 1, FIG. 2, and FIG.

As illustrated in FIG. 4, each DMA server 406 is interconnected with the other DMA servers 406 via an Internet protocol network 410. As such, there exists a peer-to-peer connection 412 between each DMA server 406 in the system 400. As described in detail below, the DMA servers 406 can handle telephony traffic that is communicated at each antenna 404. For example, the DMA servers 406 can switch and route calls received via each antenna 404. Additionally, the DMA servers 406 can hand-off calls to each other as mobile communications devices move around and between the cellular coverage sites 402. The DMA servers 406 can communicate with each other via the IP network 410 and can further transmit calls to each other via the IP network 410. It should be understood that more than four cellular coverage sites 402 can be included in the system and that the inclusion of only four cellular coverage sites 402 in FIG. 4 is merely for clarity and explanation purposes.

Within the distributed and associative telecommunications system 400 the controlling logic can be distributed and decentralized. Moreover, the wireless coverage provided by the disclosed system 400 is self-healing and redundant. In other words, due to the interconnectivity via the IP network 410, if

one or more of the DMA servers **406** loses powers, fails, or is otherwise inoperable, telephony traffic handled by the inoperable DMA server **406** can re-routed to one of the remaining operable DMA servers **406**. Additionally, user data stored in a database, e.g., a home locator resource (HLR) or a visitor 5 locator resource (VLR), can be distributed equally and fully among all of the DMA servers **406**. It can also be appreciated that new cellular coverage sites can be easily added to the system **400** as the demand for users increases. Specifically, a DMA server can be deployed as described below, connected to an antenna, connected to the IP network, and activated to provide cellular coverage in a new area.

FIG. 5 shows an exemplary, non-limiting, detailed embodiment of a DMA server, e.g., one of the DMA servers 406 described in conjunction with FIG. 4. Further, any of the 15 DMA servers 100, 200, 300 shown in FIG. 1, FIG. 2, and FIG. 3 can include the components depicted in FIG. 5 and described herein.

In a particular embodiment, the DMA server **406** is essentially a processor, or computer, having a housing and a computer readable medium **500** that is disposed therein. A power supply **502** can also be disposed within the housing of the DMA server **406** in order to provide power to the DMA server **406**. The power supply **502** can be a rechargeable battery disposed within the DMA server **406** or it can be external to 25 the DMA server **406**, i.e., a standard power outlet. Moreover, a cooling system **504**, e.g., a fan with a thermostat, can be within the DMA server **406** in order to keep the DMA server **406** from overheating. In an alternative embodiment, the DMA server **406** can be a single board processor that does not 30 require a fan.

As depicted in FIG. 5, the DMA server 406 may include a mobile switching center (MSC) module **506** and a base station controller (BSC) module 508 embedded within the computer readable medium **500**. In an exemplary, non-limiting 35 embodiment, the MSC module 506 can include a gatekeeper (GK) **510** that is connected to several gateways. For example, a circuit gateway (CGW) 512 can be connected to the GK 510 and can provide connectivity to an integrated services digital network/public switched telephone network (ISDN/PSTN) 40 interface 514. The CGW 512 can provide a circuit switched to packet data conversion. In an exemplary, non-limiting embodiment, the PSTN portion of the ISDN/PSTN interface **514** can be an inter-office interface that uses the Bellcore industry standard ISDN user part (ISUP) signaling on a sig- 45 naling system seven (SS7) link set. Moreover, the voice trunks on this interface can be timeslots on a T1 connection. Inbound and outbound voice calls can be supported on the ISDN portion of the ISDN/PSTN interface 514.

As further illustrated in FIG. **5**, a packet data server node (PDSN) gateway **516** for CDMA, or a Gateway GPRS Support Node (GGSN) for Global System for Mobile Communication (GSM), and a Session Initiation Protocol (SIP) gateway **518** can also be connected to the GK **510**. The PDSN gateway **516** and the SIP gateway **518** can provide connectivity to an IP interface **520**. Further, the PDSN gateway **516** or a GGSN can establish a reverse tunnel with the PDSN or GGSN gateway **516** using generic routing encapsulation (GRE). Moreover, the PDSN gateway **516**, or GGSN, can implement the Pseudo Random Function (PRF)/Foreign 60 Agent (FA) functionality of the DMA server **406** which supports mobile IP functions.

FIG. 5 further shows an SS7 gateway 522 that provides connectivity to an American National Standards Institute 41 (ANSI-41) and GSM Mobile Application Part (MAP) interface 524. In a particular embodiment, the ANSI-41 interface can be an SS7 TCAP/SCCP interface on the same SS7 link set

8

used for ISUP signaling. The same SS7 point code can be used to identify the DMA server 406 in the ANSI-41 network. The ANSI-41 interface can be used for roamer registration. Further, in an exemplary, non-limiting embodiment, the GSM MAP interface can be an SS7 TCAP/SCCP interface on the same SS7 link set used for ISUP signaling. It can be appreciated that there are different protocols of MAP from MAP/B to MAP/I, but in the illustrative embodiment, the different MAP/x protocols are not stacked—they are used independently. As described with reference to FIG. 11, the SS7 interface may be included in either the DMA server 406 or the DMA gateway 1102.

As depicted in FIG. 5, a media gateway 526 can also be coupled to the GK 510. In an exemplary, non-limiting embodiment, the media gateway 526 can include cellular transcoders, one or more intranet gateways, conferencing bridges, and group calling functionality. Further, an authentication, authorization, and accounting (AAA) module 528 can be coupled to the GK 510. In an exemplary, non-limiting embodiment, there are three levels of authentication management. The highest level is for administration, the mid-level is for operations, and the lowest level is for normal users. The functions of the AAA module 528 can be included in the user level.

In an exemplary, non-limiting embodiment, the GK 510 can act as an AAA server and a feather server to support advanced supplementary service, short message service, etc. Moreover, the GK 510 can act as a call manager and can support ISUP and PSTN function calls. Additionally, the GK 510 can act as a signal gateway, e.g., IP to SS7 inter-working, ISUP, GSM MAP or ANSI-41 to PSTN and ANSI-42/GSM. The GK 510 can also function as a data call server.

As illustrated in FIG. 5, the BSC module 508 includes a cellular radio network controller (CRNC) 530 and a cellular selection/distribution unit (CSDU) 532 that are connected to a call protocol controller (CPC) 534. In turn, the CPC 534 can be connected to a plurality of base transceiver stations (BTSs) **536**. Specifically, the DMA server **406** includes a BTS interface **538** at the CPC **534** that can be physically and directly connected to the BTSs 536. The CRNC 530 can provide cellular radio resource management and cellular call control. The CSDU **532** can provide Fundamental Channel (FCH) soft handoff and distribution, Link Access Control (LAC) processing for inband signaling, multiplexer (MUX) functions, and centralized power control. Further, the CPC 534 can convert a T1 or E1 message or ATM interface to a data packet message. In a particular embodiment, each BTS **536** supports signals and traffic up to the front point of the CPC **534**, e.g., up to the BTS interface **538**. Further, in a particular embodiment, the CRNC 530, the CPC 534, the CSDU 532 and the OAMP **540** can perform one or more of the functions of legacy Base Station Controllers (BSC).

In an exemplary, non-limiting embodiment, the BTS interface 538 can be an IS-95A OR IS-2000 interface over E1 or ATM, or the BTS interface 538 can be a GSM BTS interface using MAP or customized application for mobile network enhanced logic (CAMEL). In an illustrative embodiment, the CPC 534 can be connected to one or more BTSs 536. FIG. 5 further shows that the BSC module 508 includes an operations, administration, maintenance, and provisioning (OAMP) module 540. In an exemplary, non-limiting embodiment, the OAMP module 540 can use simple network management protocol (SNMP) for operations interfaces. Further, the OAMP module 540 can include a JAVA user interface. The OAMP module 540 can also include a software agent that is assigned to each component within the DMA server 406.

The agents independently monitor their respective components. Moreover, each agent can provision its respective component.

When deployed in a network, such as illustrated in FIG. 4, embodiments of DMA servers are configured to handle the handing off of communications when, for example, a mobile device passes from a coverage site 402 (FIG. 4) covered serviced by one DMA server 406 to another coverage site 402 serviced by another DMA server 406. As previously described, the DMA servers 406 participate in an IP network 410 through which the communications are routed between the DMA servers 406. However, in not all cases will the DMA servers 406 be able to participate as peers in an IP network 410. For example, if one or more of the coverage sites 402 are in rural locations or other locations remote from other coverage sites 402, there may not be access to the IP network 410 in the remote coverage sites **402**. Accordingly, embodiments of the present disclosure describe DMA gateways to enable DMA servers to communicate with one another when one or more of the DMA servers cannot participate directly in the IP network. In addition, embodiments of the DMA gateways also enable legacy networks and devices participating in the legacy networks to communicate with devices serviced by one or more of the DMA servers as further described below.

Because of the mobility of various forms of the DMA servers and devices that may communicate via these servers, as well as the DMA gateways described below, the communications network accounts for the movement of these devices. In other words, as the devices move, information regarding the accessibility of these devices and how communications are routed among them is dynamic. Thus, even when such devices move during the course of a communication, information pertaining to the routing of the communication is updated to support continuation of the communication.

FIG. 6 illustrates a network 600 that includes a first DMA gateway (abbreviated as "DMAG" in FIG. 6 and other figures) 602 and a second DMA gateway 604 that communicate with each other over a DMA gateway network 606. The DMA 40 gateway network 606 may include a dedicated wired or wireless communication medium or be included within a network carrying other communications. The second DMA gateway 604 communicates with a legacy network that, for example, includes a public switched telephone network 610 that ser- 45 vices communication with wired, landline devices such as landline telephone **612**. The DMA gateway also may enable communication with public IP networks that enable data communications, Voice over Internet Protocol (VoIP) communications, and other communications, as well as other 50 types of legacy networks. Although a pair of DMA gateways 602 and 604 and a single legacy network 610 are shown in FIG. 6, any number of DMA gateways and legacy networks may participate in the network 600.

In addition to the DMA gateways 602 and 604 and the 55 legacy network 610, the network 600 includes two groups of DMA servers in which the DMA servers communicate with each other over separate private IP networks. For example, in a first group communicating via a first private IP network 620, three DMA servers 622, 624, and 626 communicate with each other. In a second group communicating via a second private IP network 640, three DMA servers 642, 644, and 646 communicate with each other. Two different groups each including three DMA servers are shown for illustration. However, it will be appreciated that any number of groups of DMA servers could communicate with each other within each of the groups, and any number of groups could be bridged using

10

DMA gateways as described below to enable communications between devices associated with different DMA servers in different groups.

Each of the DMA servers may service a plurality of voice and/or data communications devices. For example, a first DMA server 622, through an associated wireless transceiver, may service a plurality of communications devices such as a first wireless telephone device **632**. As previously described with reference to FIG. 4, the first wireless telephone device 632 may communicate with devices serviced by other DMA servers that participate in the first private IP network 620. Thus, for example, the first wireless telephone device 632 would be able to engage in voice and/or data communications with a second wireless telephone device 634 serviced by a second DMA server 624. Also, it should be appreciated that the second wireless telephone device may communicate with other devices, such as a third wireless telephone device 636 that is serviced by a same DMA server, such as the second DMA server **624**. Although the DMA servers in FIG. **6** are only shown servicing wireless telephone devices, it should be appreciated that other devices, such as computers and other communication devices also may participate in the network 600 by communicating through the DMA servers.

As shown in FIG. 6, the groups of DMA servers commu-25 nicating via the two private IP networks **620** and **640** are separate networks. The wireless telephone devices 632, 634, and 636 serviced by DMA servers 622 and 624 participating in the first private IP network **620** do not have a network connection with any of the DMA servers 642, 644, and 646 that communicate with each other via the second private IP network. Thus, a fourth wireless telephone device 652 in communication with a fourth DMA server **642** can communicate with a fifth wireless telephone device **654** serviced by a fifth DMA server 644 because the DMA servers 642 and 644 can communicate with each other via the second private IP network **640**. Similarly, the sixth wireless telephone device 656 and the seventh wireless telephone device 658 can communicate with each other through the sixth DMA server 646 with which each communicates and each can communicate with the other wireless telephone devices 652 and 654 serviced by the other DMA servers 642 and 644 participating in the second private IP network. However, without a bridge between the first private IP network 620 and the second private IP network **640**, neither the DMA servers nor the wireless telephone devices serviced by each of the private IP networks 620 and 640 can communicate with devices serviced by the other private IP network. Similarly, neither the DMA servers nor the wireless telephone devices serviced by each of the private IP network 620 and 640 can communicate with the public switched telephone network 610 or any of the devices, such as the landline telephone device **612**, serviced by the public switched telephone network 610.

Embodiments of the present disclosure enable devices on separate networks to communicate with each other via DMA gateways that bridge separate network and communications systems. In the example of FIG. 6, the first private IP network 620 communicates with the first DMA gateway 602 and the second private IP network 640 communicates with the second DMA gateway 604. The DMA gateways 602 and 604 are configured to route communications from one private IP network to another and the DMA gateways 602 and 604 are in communication with each other via the DMA gateway network 606. As a result, the DMA gateways 602 and 604 can route communications from the DMA servers 622, 624, and 626 and the devices they service to the DMA servers 642, 644, and 646 and the devices they service and vice versa. Also, because the second DMA gateway is coupled with the second

public switched telephone network 640, the wireless telephone devices 652, 654, 656, and 658 and other devices serviced by the DMA servers 642, 644, and 646 can communicate with the landline telephone device 612 and other devices serviced by the public switched telephone network 610. In short, the DMA gateways can provide communications between wireless devices serviced by associated DMA servers and wired or wireless devices serviced by legacy networks coupled with the DMA gateways.

To facilitate communications between devices serviced by 10 different networks, the DMA gateways 602 and 604 maintain information identifying the devices that each services. For example, when the first wireless telephone device 932 initiates a communication to the fourth wireless telephone device 952, the first DMA gateway 602 accesses data identi- 15 fying what other DMA gateway, if any, services the fourth wireless telephone device and which DMA server or other network or device associated with the first DMA gateway services the targeted fourth wireless telephone device 952. DMA gateways provide information to one another regarding 20 the communications networks they service by exchanging register data describing the networks they service. The register data describes devices for which the networks they service are the home network as well as for what devices are visiting on their networks. This information is exchanged directly 25 between the DMA gateways or through a central database described further below with reference to FIG. 10.

A DMA server may associate itself with different DMA gateways. For example, as described with reference to FIGS. 1 and 2, a DMA server may include a mobile device that is 30 easily moved from one place to another. A mobile DMA server that communicates wirelessly with a private IP network and the DMA gateway servicing that private IP network may move out of communications range of a DMA gateway with which it was previously associated into communications 35 range with another DMA gateway. For further example, for purposes of traffic management, fault tolerance, or other reasons, it may be desirable to reassociate a DMA server previously associated with one DMA gateway to another DMA gateway. This reassociation may be initiated manually or 40 automatically by the DMA server, the DMA gateway, or any combination thereof. Thus, for example, the fourth DMA server **642** may be reassociated with the first private IP network **620** and the first DMA gateway **602** servicing the first private IP network **620** as shown by the dashed line **660** in 45 FIG. 6. Because the DMA gateways 602 and 604 bridge the private IP networks 620 and 640, devices serviced by the fourth DMA server **642**, such as the fourth wireless telephone device 652 may continue to communicate with the wireless telephone devices 654, 656, and 658 serviced by the DMA 50 servers **644** and **646** associated with the second private IP network 640.

The DMA gateways and DMA servers can be arrayed in any number of ways to facilitate the deployment and proliferation of communications networks. For example, FIG. 7 55 illustrates a network 700 that includes satellite-based DMA gateways including a first satellite-based DMA gateway 702 and a second satellite-based DMA gateway 704. The satellite-based DMA gateways 702 and 704 are placed in orbits suitable to enable communications with ground-based private IP networks 720 and 740 and a ground-based legacy network 710. The satellite-based DMA gateways 702 and 704 communicate with each other via a satellite communications network 706. The second satellite-based DMA gateway 704 communicates with a legacy network, such as a public 65 switched telephone network 710, over a communications uplink 714 via the same satellite communications network

12

and 704 communicate or another uplink communications medium. The satellite-based DMA gateways 702 and 704 communicate with private IP networks 720 and 740 that may include ground-based private IP networks, via the same satellite communications network 706 or other uplink communications media. An advantage of including satellite-based DMA gateways is the ability to bridge DMA servers or groups of DMA servers with one another even though the DMA servers or groups of DMA servers may be disposed remotely from each other where ground-based DMA gateways or ground-based communications media between the DMA servers are overtaxed, unreliable, unavailable, or otherwise undesirable.

Using the satellite-based DMA gateways 702 and 704, communications between the DMA servers, the devices they serve, and the legacy network operates in a similar manner to the communications between devices as described with reference to FIG. 6. A first group of DMA servers 722, 724, and 726 communicate via a first private IP network 720. A first wireless telephone device 732 in communication with a first DMA server 722 is able to communicate with a second wire telephone device **734** in communication with a second DMA server 724 via the first private IP network 720. Further, the first wireless telephone device 732 is enabled, via the first DMA server 722 and the first private IP network 720, to communicate with the first DMA gateway 702. Then, via the satellite communications network 706, the first DMA gateway 702 is able to communicate with the second DMA gateway 704 to enable communications with devices served by the second private IP network **740**. Thus, the DMA gateways 702 and 704 allow the first wireless telephone device 732 to communicate with a third wireless telephone device 762 even though the wireless telephone devices 732 and 762 participate in separate private IP networks 720 and 740. In addition, because the second DMA gateway 704 is in communication with both the second private IP network 740 and the public switched telephone network 710, the second DMA gateway 704 enables mobile-to-land communications between third wireless telephone device 762 and a wired landline device 712. The use of satellite-based DMA gateways 702 and 704 enables this communication even a vast distances separate the communication devices and there are little or no land-based communications networks between the devices.

FIG. 8 illustrates a communications network 800 in which, instead of utilizing satellite-based DMA gateways, employs a ground-based DMA gateway 830 facilitating communications between satellite-based DMA servers **810** and **820**. In areas where, for example, a ground-based DMA server cannot be employed or the distance between wireless communication devices **812** and **814** is so large that one or more DMA servers may not be able to effectively service the wireless communication devices **812** and **814**, it may be desirable to enable communications with the deployment of satellitebased DMA servers such as DMA servers 810 and 820. In such a case, the wireless communications devices 812 and 814 may include wireless satellite communications devices or other devices with access to a satellite uplink communications medium. As in the case of DMA servers previously described, a first wireless communications device 812 in communication with a first DMA server **810** may wirelessly communicate with a second wireless communications device **814** is also in communication with the first DMA server **810**.

In addition, because the first DMA server **810** is in communication with a ground-based DMA gateway **830** via a suitable uplink communications medium **840**, the first DMA server **810** is able to route communications between the

devices it serves and other devices in communication with the DMA gateway 830. For example, the DMA gateway 830 is in communication with a first ground-based DMA server 850 that services a first wireless telephone device 852. As a result, the wireless communications devices **812** and **814** are able to 5 communicate with the first wireless telephone device 852. Similarly, the DMA gateway 830 also is in communication with a private IP network 880 that provides communications between the second satellite-based DMA server 820 and two ground-based DMA servers 860 and 870. As a result, the 10 DMA gateway 830 enables communications between the wireless communications devices 812 and 814 serviced by the first satellite-based DMA server 810, the first wireless telephone device 852 serviced by the ground-based DMA server 850, a second wireless telephone device 862 serviced 15 by a second ground-based DMA server **860**, a third wireless telephone device 872 serviced by a third ground-based DMA server 870, and any devices (not shown in FIG. 8) serviced by the second satellite-based DMA server 820. In addition, if the DMA gateway 830 were in communication with one or more 20 legacy networks, the DMA gateway 830 could enable communications between devices serviced by the legacy networks and devices serviced by the DMA servers 810, 820, 860, and 870 in communication with the DMA gateway 830.

FIG. 9 illustrates a communications network 900 illustrating how a communications network may include a combination of satellite-based and ground-based DMA servers and satellite-based and ground-based DMA gateways. Embodiments of the present disclosure are not restrictive to including only ground-based or satellite-based DMA gateways were 30 DMA servers and thus provide flexibility in creating and proliferating communications networks based on the communications needs for which the network is deployed.

A first satellite-based DMA server 910 communicates with wireless communications devices **912** and **914**. The first satellite-based DMA server 910 also is in communications a satellite communications network **940** and a private IP network 950. Via the satellite communications network 940, first the satellite-based DMA server is able to communicate with a satellite-based DMA gateway 930 to, for example, enable 40 communications between devices served by a first groundbased DMA server, such as a first wireless telephone 992. Via the private IP network 950, the satellite-based DMA server 910 also is able to communicate with other DMA gateways, such as a first ground-based DMA gateway 960 and a second 45 ground-based DMA gateway 970. Thus, the devices served by the satellite-based DMA server 910 would be able to communicate with devices in communication with the ground-based DMA gateways 960 and 970, such as the second wireless telephone device 974 that is serviced by a second 50 ground-based DMA server 972 in communication with the second ground-based DMA gateway 970. In sum, as described in the particular illustrative embodiments depicted in FIGS. 6-9, satellite-based or ground-based DMA servers and satellite-based or ground-based gateways can be 55 deployed as desired to enable communications between various communications devices.

To facilitate communications between devices serviced by different networks, the DMA gateways maintain information identifying the devices that each services. For example, a user of a wireless telephone device serviced by a first DMA server may send a communication to the user of the target wireless telephone device that is serviced by a second DMA server. The first and second DMA servers both are in communication with a DMA gateway that enables communications between 65 the devices serviced by the different DMA servers. The DMA gateway is configured to route the communications by access-

14

ing information indicating which DMA servers provide service to which wireless devices. The DMA gateway may maintain the information locally in the DMA gateway or access information maintained in a central register accessible to the DMA gateway. When the information is maintained locally in the DMA gateway, DMA gateways in the network provide information to one another regarding the devices they service by exchanging register data describing the devices they service. The register data describes devices for which the networks they service are the home network as well as for what devices are visiting on their networks. This information is exchanged directly between the DMA gateways or through a central database described further below with reference to FIG. 10.

FIG. 10 shows a network 1000 including a pair of DMA gateways 1010 and 1050 that facilitate communications between devices on different types of networks. A first DMA gateway 1010 communicates with a plurality of DMA servers 1012, 1014, and 1016 and a plurality of legacy networks 1020, 1030, and 1040. As described below with reference to FIG. 11, the DMA gateway 1010 includes interfaces configured to communicate with a PSTN 1020, a mobile switching center (MSC) 1030 such as used by wireless telephones and communications devices, and a public IP network 1040. The DMA gateway 1010 thus permits communication between devices serviced by the DMA servers 1012, 1014, and 1016 and devices serviced by the associated legacy networks 1020, 1030, and 1040.

In addition, the DMA gateway 1010, through the satellite communications network 1080 or other DMA gateway network, communicates with other DMA gateways to support communications between the devices serviced by different DMA gateways. For example, the second DMA gateway 1050 is associated with a private IP network 1060 that services a plurality of DMA servers 1052, 1054, 1056 and the devices they serve. Thus, through the DMA gateways 1010 and 1050, devices serviced by one of the DMA servers 1012, 1014, and 1016 or devices serviced by the legacy networks 1020, 1030, and 1040, can communicate with devices serviced by the DMA servers 1052, 1054, and 1056 or other networks serviced by the second DMA gateway 1050. The private IP network 1060 also includes a central register database 1070 that maintains information serviced by DMA gateways and DMA servers within the network 1000. The operation of this central register database 1070 is described further below.

As shown in FIG. 10, one or more of the DMA servers 1012, 1014, and 1016 may communicate directly with a respective DMA gateway, such as DMA gateway 1010, through a satellite uplink or other communications medium. Alternatively, one or other DMA servers 1052, 1054, and 1056 may communicate with a DMA gateway, such as DMA gateway 1050, via a private IP network 1060 in which the DMA servers 1052, 1054, and 1056 and the DMA gateway **1060** participate. When a DMA server communicates with a DMA gateway over a private IP network, the respective DMA server and DMA gateway may communicate with each other by transmitting IP packet data over the private IP network. On the other hand, when the DMA server communicates with the DMA gateway via a different medium, the DMA server and DMA gateway may communicate with each other according to the protocol of the available medium.

In the networks of FIGS. 6-10, embodiments of DMA gateways exchange communications information identifying devices serviced by one or more DMA servers or other communications networks that the DMA gateways service. When a DMA gateway detects that it is in communications range

with one or more DMA servers, the DMA gateway sends communications information from the DMA servers or other communications networks to one or more other DMA gateways or to a central database, such as the central register database 1070. The communications information may 5 include a notification of what DMA server or servers with which the DMA gateway is in communication. As DMA gateways move between communications ranges of various DMA servers or vice versa, the DMA gateways may send additional notifications or other information to update the 10 previously-communicated communications information as to what communications networks are accessible to the various DMA gateways.

The communications information, in one embodiment, includes register information, such as home location register (HLR) information and visitor location register (VLR) information maintained by the DMA servers or other communications networks. As described with reference to FIG. 1 and FIG. 2, because a DMA server may include a portable or mobile device, the DMA server information also may identify whether the DMA gateway is a home gateway for the DMA server or whether the DMA server is temporarily registered with the DMA gateway in a visitor DMA register.

When another DMA gateway receives the DMA server information from a first DMA gateway, a second DMA gateway stores the DMA server information in a home DMA register in which the second DMA gateway also stores information regarding the devices it services. The second DMA gateway receives a communication from one of the devices it services targeted for a wireless device that is serviced by the 30 first DMA gateway. The second DMA gateway then routes the communication via a DMA gateway network to the first DMA gateway. The first DMA gateway, using its own home DMA register storing information about the devices is services, then directs the communication to the network and/or 35 DMA server that services the targeted communications device.

When the DMA gateway receives DMA server information about one or more DMA services associated with the DMA gateway or information about other networks the DMA gateway services, the DMA gateway may provide the DMA server information to other DMA gateways in a number of ways. For example, the DMA gateway may send a notification to other DMA gateways that is has received the DMA server information and that the DMA server information can 45 be retrieved from the DMA gateway or, as described below, from a central database. The DMA server information is then transmitted to other DMA gateways in response to queries from one or more gateways requesting the DMA server information. Alternatively, the DMA gateway may automatically send the DMA server information to other gateways upon receiving the DMA server information.

Instead of or in addition to sending the DMA server information to other DMA gateways, the DMA gateway may send the DMA server information to a central database as shown in 55 FIG. 10. Then, for example, when a DMAG gateway such as DMA gateway 1010 is in communications range of a DMA server such as DMA server 1012, the DMA server information is sent to the central register database 1070. The DMA server information is sent from the DMA gateway 1010 via 60 the satellite communications network 1080 to the DMA gateway 1050 where the DMA server information is routed via the private IP network 1060 to the central register database. Thus, as DMA server networks and other networks are added to the system, the DMA gateway servicing each of these communications networks receives the communications information for the communications network and sends the communications

16

tions information to the central register database 1070. Then, other DMA gateways each can receive the new communications information from the central register database 1070.

The new communications information may be automatically sent by the central register database 1070 via the DMA gateway 1050 that services the central register database. Alternatively, when new communications information is received, the DMA gateway receiving the communications information or the central register database 1070 may send a notification to other DMA gateways that the new information is available for retrieval.

FIG. 11 shows an operating environment 1100 including a plurality of networks serviced by a DMA gateway 1102. The DMA gateway 1102 services networks through a plurality of interfaces configured to support different types of networks. The DMA gateway 1102 communicates with a private IP network 1104, such as that used to communicate with one or more DMA servers and/or a central register database as shown in FIG. 7, via a data network interface 1106. The DMA gateway 1102 communicates with the DMA gateway network, which in this example includes a satellite network 1108, via a satellite network interface 1110. In addition, the DMA gateway 1102 includes one or more interfaces that enable the DMA gateway 1102 to communicate with one or more legacy networks. For example, the DMA gateway 1102 communicates with a public switched telephone network (PSTN) or integrated services digital network (ISDN) 1112 via a PSTN/ISDN interface 1114. The DMA gateway 1102 communicates with a public IP network **1116** via a public IP interface 1118 that enables the DMA gateway 1102 to, for example, exchange Internet data or voice over Internet protocol (VoIP) calls. The DMA gateway 1102 also communicates with a wireless network 1120 via a mobile device interface 1122. The DMA gateway 1102 also communicates with an ANSI-41 network **1124** via an SS7 TCAP/SCCP interface 1126 operable to be used in ISUP signaling, DMA server identification, roamer registration, and other functions described with reference to the SS7GW interface 522 described with reference to FIG. 5.

One or more processors 1130 is coupled with the interfaces 1106, 1110, 1114, 1118, and 1122 and a memory device 1140. The memory device 1140 may include one or more of a random access memory, including volatile and nonvolatile rewritable memory devices, a read-only memory, and data storage devices. The memory device **1140** maintains a plurality of software modules providing executable instructions to the processor 1130 to support for the functions of the DMA gateway 1102. The modules include one or more gateway modules 1142 that include the operating system and basic control software that enables the processor 1130 to interact with its network interfaces. One or more conversion modules **1144** control the translation of data and data formats used by one of the networks to that of one or more other networks to which data is to be communicated. One or more routing modules 1146 provide instructions to the processor for routing communications between the appropriate interfaces. The routing instructions use information about the accessibility of devices through various servers, gateways, and networks. Thus, as information about a communication is received, routing instructions are provided indicating through which DMA gateways the communication is to be directed from its source to its destination.

One or more legacy network communications modules provide instructions for the processor 1130 to interact with each of the legacy communications network interfaces 1114, 1118, 1122. One or more DMA detection modules 1152 provide instructions to the processor for detecting the pres-

ence of accessible DMA servers and integrating the servers into the DMA network. One or more register data management modules 1154 receive, maintain, and/or forward register data for various networks and devices. The one or more register data management modules 1154 are operably coupled 5 with a community location register (CLR)/visitor location register gateway (VLR)/gateway (GW)/global title (GT) (collectively, CVGG) data storage 1160 to maintain register data for DMA servers and other networks that communicate through the DMA gateway 1102. The register data stored by 10 embodiments according to the present disclosure are described below with reference to FIGS. 9 and 10.

The DMA gateway 1102 may be implemented in a number of forms. For example, the DMA gateway 1102 may be implemented as an orbiting satellite, as described with refer- 15 ence to FIGS. 6 and 7. Alternatively, the DMA gateway 1102 may include either a fixed or portable ground station. The DMA gateways 1102 communicate with each other through a gateway network. In the example of FIGS. 6 and 7, the gateway network includes a satellite communications network. 20 However, if the DMA gateways include only ground-based stations, the gateway network may include a point-to-point network facilitated by microwave communications, optical or other cabled connections, or other types of communications systems. If the gateway network includes both orbiting and 25 ground-based stations, the gateway network may include a combination of satellite-based and non-satellite based communications systems.

FIGS. 12 and 13 show tables depicting how communications information including register data is stored in the DMA 30 gateways or a central register database. The tables in FIGS. 12 and 13 are a logical representation. The entries within the tables do not represent a single value as might be found, for example, in a single entry of a spreadsheet document. Instead, the entries within the rows and columns of the table represent 35 a category of information stored within the table.

In the example of FIGS. 12 and 13, representative data is shown for three DMA gateways and three DMA servers, although data for any number of DMA gateways and DMA servers participating in a DMA network may be included in 40 server register data tables. In this example, it is assumed that each DMA gateway is in communication with a respective DMA server designated with the same number, e.g., DMA gateway 1 is in communication with DMA server 1, etc. FIG. 12 shows tables 1200 and 1250 representing the register data stored in 45 stored. At 1 each of DMA gateway 1 and DMA gateway 2, respectively, while FIG. 10 shows a table 1000 representing the register data stored in a central register database for the three DMA gateways.

In the table 1200 for the DMA gateway 1, three rows 1210, 50 1212, and 1214 store register data for each of the respective DMA servers, DMA server 1, DMA server 2, and DMA server 3. In a CLR database column 1220, CLR data is stored for each of the three DMA servers and, in a VLR database column 1222, VLR data is stored for each of the three DMA servers. In DMAG 2 Community HLR database column 1224 and DMAG 3 Community HLR database column 1226, the HLR data for each of the DMA servers is stored for DMA gateway 2 and DMA gateway 3, respectively. In a Visitor DMA Server Register column 1228, data is stored for one or 60 more DMA servers that are temporarily registered with DMA gateway 1.

In the table 1250 for the DMA gateway 2, three rows 1260, 1262, and 1264 store register data for each of the respective DMA servers, DMA server 1, DMA server 2, and DMA 65 server 3. In a CLR database column 1270, CLR data is stored for each of the three DMA servers and, in a VLR database

18

column 1272, VLR data is stored for each of the three DMA servers. In DMAG 1 Community HLR database column 1274 and DMAG 3 Community HLR database column 1276, the HLR data for each of the DMA servers is stored for DMA gateway 1 and DMA gateway 3, respectively. In a Visitor DMA Server Register column 1278, data for one or more DMA servers that are temporarily registered with DMA gateway 2.

Referring to FIG. 13, in the table 1300 for the central register database, three rows 1310, 1312, and 1314 store register data for each of the respective DMA servers, DMA server 1, DMA server 2, and DMA server 3. In a DMA gateway 1 HLR database column 1320, HLR data is stored for each of the three DMA servers. In a DMA gateway 1 VLR database column 1322, VLR data is stored for each of the three DMA servers. In DMAG 1 Visitor DMA server register column 1324, data is stored for one or more DMA servers that are temporarily registered with DMA gateway 1. In a DMA gateway 2 HLR database column 1326, HLR data is stored for each of the three DMA servers. In a DMA gateway 2 VLR database column 1328, VLR data is stored for each of the three DMA servers. In DMAG 2 Visitor DMA server register column 1330, data is stored for one or more DMA servers that are temporarily registered with DMA gateway 2.

FIG. 14 shows a flow diagram 1400 of an exemplary process for routing communications using DMA gateways. In the example of FIG. 14, a first DMA server comes in communications range or otherwise becomes accessible to a first DMA gateway while a legacy communications network becomes accessible to a second DMA gateway.

At 1402, information is received at a first DMA gateway indicating the location of register data for a DMA server. This register data may be stored in another DMA gateway or a central register database. At 1404, information is received indicating that a second DMA gateway is in communication with a legacy communications network. At 1406, it is detected that the first DMA server is now in communications range of the first DMA gateway. At 1408, the first DMA gateway receives the DMAS register data for the first DMA server from the location identified at 1402. As previously described, this information may be automatically transmitted to the first DMA gateway when it comes within communications range of the first DMA server or the first DMA gateway may request the information from the location where it is stored.

At 1410, information is received that relates to a data and/or voice communication placed by a mobile device associated with the first DMA server. The information indicates that the communication is directed or placed to a target device accessible via the legacy communications network. The accessibility of the legacy communications network to the second DMA gateway was previously identified to the first DMA gateway at 1404. Thus, at 1412, the communication information is routed from the first DMA gateway to the second DMA gateway. The process ends at 1414. The process repeats indefinitely as desired to relay communications using the DMA gateways.

FIG. 15 shows a flow diagram 1500 of an exemplary process for routing communications to a DMA gateway depending on whether the DMA gateway communicates with a server through a private IP network or through another medium. At 1502, routing instructions are received at a DMA server from a DMA gateway when the DMA server is in communication with the DMAG, such as when the DMA gateway comes within communications range of the DMA server. At 1504, a communication is received at the DMA server from a mobile communications device via a wireless

transceiver coupled to the DMA server. At 1506, it is determined whether the DMA server communicates with the DMA gateway via a private IP network. If so, at **1510**, packet data related to the communication is sent as packet data over the private IP network that is received by the DMA gateway via its private IP network interface. On the other hand, if it is determined at **1506** that the DMA server does not communicate with the DMA gateway via a private IP network, at 1512, the information related to the communication is transmitted to the DMA gateway via another medium, such as a direct 10 satellite uplink. The information related to the communication is thus received by the DMA gateway via a satellite communications network interface.

At 1514, the communication is routed from the DMA gateway to the destination device. The communication is 15 routed using information received and maintained by the DMA gateway as described, for example, in FIG. 14. The process ends at **1516**. The process repeats indefinitely as desired to relay communications using the DMA gateways.

The above-disclosed subject matter is to be considered 20 illustrative, and not restrictive, and the appended claims are intended to cover all such modifications, enhancements, and other embodiments, which fall within the true spirit and scope of the present invention. Thus, to the maximum extent allowed by law, the scope of the present invention is to be 25 determined by the broadest permissible interpretation of the following claims and their equivalents, and shall not be restricted or limited by the foregoing detailed description.

What is claimed is:

1. A method, comprising:

receiving at a first distributed mobile architecture (DMA) gateway communications information for a communications network accessible by a second DMA gateway, the communications information indicating one or more devices accessible by one of a DMA server and a legacy 35 communications network, wherein the first DMA gateway and the second DMA gateway participate in a DMA gateway communications network;

storing the communications information in a home DMA register of the first DMA gateway;

receiving a communication at the first DMA gateway for a target device indicated by the communications information to be served by the second DMA gateway; and

routing the communication from the first DMA gateway to the target device by relaying the communication from the first DMA gateway to the second DMA gateway via the DMA gateway communications network.

- 2. The method of claim 1, wherein:
- at least one of the first DMA gateway and the second DMA gateway includes a satellite-based DMA gateway; and the DMA gateway communications network includes a satellite communications network.
- 3. The method of claim 1, wherein the DMA server includes one of:
 - a ground-based DMA server; and
 - a satellite-based DMA server.
- 4. The method of claim 1, wherein the communication includes at least one of:
 - a voice communication; and
 - a data communication.
- 5. The method of claim 1, wherein the legacy communications network includes one of:
 - a public switched telephone network (PSTN);
 - a wireless communications network serviced by mobile 65 switching center (MSC);
 - a public internet protocol (IP) network; and

20

- an American National Standards Institute 41 (ANSI-41) network.
- 6. The method of claim 1, further comprising the first DMA gateway sending a notification to the second DMA gateway, the notification indicating that the communications information is stored at the first DMA gateway.
- 7. The method of claim 1, further comprising, upon receiving the communications information, the first DMA gateway automatically sending at least a portion of the communications information to the second DMA gateway via the gateway communications network.
- 8. The method of claim 1, further comprising, in response to receiving a query from the second DMA gateway for the communications information, the first DMA gateway sending at least a portion of the communications information to the second DMA gateway via the gateway communications network.
- **9**. The method of claim **1**, wherein the communications information includes communications register data including at least one of:
 - a portion of a community location register;
 - a portion of home location register (HLR) data for the communications network; and
 - a portion of visitor location register (VLR) data for the communications network.
- 10. The method of claim 9, wherein the register data stored at the first DMA gateway indicates that the register data is for a DMA server temporarily registered in a visitor DMA register of the second DMA gateway.
- 11. The method of claim 1, further comprising the first DMA gateway detecting the presence of the communications network within a communications range of the first DMA gateway.
- 12. The method of claim 11, further comprising the first DMA gateway sending communications network information to the second DMA gateway indicating that the communications network is within the communications range of the first DMA gateway.
- 13. The method of claim 11, further comprising the first DMA gateway sending communications network information to a central database indicating that the communications network is within the communications range of the first DMA gateway.
- **14**. The method of claim **11**, further comprising the first DMA gateway receiving additional communications network information from the second DMA gateway indicating that the second DMA gateway detects the presence of an additional communications network within a communications range of the second DMA gateway.
- **15**. The method of claim **1**, further comprising the first DMA gateway receiving a second notification from a central database, the second notification indicating that second register data is stored at the central database.
- 16. The method of claim 15, further comprising the first DMA gateway detecting a second communications network in a service area of the first DMA gateway.
- 17. The method of claim 16, wherein the first DMA gateway detects a private Internet Protocol (IP) network access point within a communications range of the first DMA gateway and wherein the first DMA gateway is adapted to communicate with the second communications network via the private Internet protocol (IP) network.
 - 18. The method of claim 16, wherein the first DMA gateway sends second communications information to the central database indicating that calls associated with the second communications network are accessible to the first DMA gateway.

- 19. The method of claim 18, wherein the first DMA gateway receives the second register data from the central database.
- 20. The method of claim 1, wherein the first DMA gateway receives the communications information from the second 5 DMA gateway.
- 21. The method of claim 1, wherein the first DMA gateway receives the communications information from a central database.
 - 22. A network communications system, comprising:
 - a first distributed mobile architecture (DMA) gateway including:
 - a first interface adapted to communicate with a legacy communications network;
 - a second interface adapted to communicate with a pri- ¹⁵ vate Internet Protocol (IP) network;
 - a third interface adapted to communicate with a DMA gateway communications network; and
 - a server having logic adapted to:
 - receive legacy network information from a second DMA gateway, the legacy network information indicating that the legacy communications network is in a communications range of the second DMA gateway; and
 - forward information associated with a call received from a DMA server via the second interface to the second DMA gateway via the third interface;
 - wherein the call is placed to a destination device accessible via the legacy communications network.
- 23. The system of claim 22, wherein at least one of the first DMA gateway and the second DMA gateway comprises a satellite-based DMA gateway.
- 24. The system of claim 22, wherein at least one of the first DMA gateway and the second DMA gateway comprises a ground-based DMA gateway.
- 25. The system of claim 22, wherein the DMA server includes one of:
 - a ground-based DMA server; and
 - a satellite-based DMA server.
- 26. The system of claim 22, wherein the logic is adapted to receive DMA server register data from the DMA server indicating that a mobile communications device is accessible to the DMA server via a wireless transceiver coupled to the DMA server.
- 27. The system of claim 22, wherein the first DMA gateway communicates with a central database via the third interface, the central database storing register data associated with the DMA server.
- 28. The system of claim 22, wherein the first DMA gateway communicates with a central database via the second interface, the central database storing register data associated with the DMA server.
- 29. The system of claim 22, wherein the first DMA gateway and the second DMA gateway communicate via C-Band, Ku-Band, Ka-Band, L-Band, or any combination thereof.
- 30. The system of claim 22, wherein the gateway communications network comprises at least one of an IP network and a microwave network.
- 31. The system of claim 22, wherein the legacy communications network includes one or more of:
 - a public switched telephone network (PSTN);
 - a wireless network;
 - a public IP network; and
 - an American National Standards Institute 41 (ANSI-41) network.

22

- 32. The system of claim 22, wherein the DMA server is one of a plurality of DMA servers communicating with the first DMA gateway via the second interface.
- 33. A method of routing calls via a communications network, the method comprising:
 - receiving first routing instructions at a first distributed mobile architecture (DMA) server from a first DMA gateway when the first DMA server is in a first service area of the first DMA gateway, the first DMA gateway comprising a first orbiting satellite; and
 - sending a first call received at the first DMA server from a first mobile communications device via a wireless transceiver integrated with the first DMA server to the first DMA gateway via a private Internet Protocol (IP) network according to the first routing instructions;
 - wherein the first call is placed to a destination device accessible via a legacy communications network, the legacy communications network accessible via the first DMA gateway.
- 34. The method of claim 33, wherein the first DMA server is adapted to send the first call while being transported from a first location to a second location.
- 35. The method of claim 34, wherein the first DMA server receives second routing instructions from a second DMA gateway when the first DMA server moves into a second service area of the second DMA gateway, the second service area comprising the second location and the second DMA gateway comprising an orbiting satellite.
- 36. The method of claim 35, wherein the first DMA server sends a second call received at the first DMA server from the first mobile communications device to the second DMA gateway via the private IP network according to the second routing instructions.
 - 37. The method of claim 36, wherein the second call is associated with a destination device accessible via the legacy communications network.
- 38. The method of claim 36, wherein the second call is associated with a second mobile communications device accessible to a second DMA server, the second DMA server accessible to the second DMA gateway via the private IP network.
 - 39. The method of claim 35, wherein the first DMA server receives the second routing instructions from the second DMA gateway during the first call.
 - 40. The method of claim 35, wherein the first DMA server sends first DMA server register data to the second DMA gateway in response to receiving the second routing instructions.
- 41. The method of claim 33, wherein the first DMA server receives second routing instructions from a second DMA gateway when the first DMA server leaves the first service area and enters a second service area of the second DMA gateway due to orbital motion of the first DMA gateway and the second DMA gateway, the second DMA gateway comprising an orbiting satellite.
 - 42. A network communications system, comprising:
 - a distributed mobile architecture (DMA) server coupled to a wireless transceiver, the DMA server including:
 - a first interface adapted to communicate with a private Internet Protocol (IP) network;
 - a second interface adapted to communicate with a gateway communications network; and
 - a server having logic adapted to:
 - receive a call from a mobile communications device via the wireless transceiver; and
 - send call information related to the call to a DMA gateway;

- wherein the call is placed to a destination device accessible via a legacy communications network, the legacy communications network accessible via the DMA gateway.
- 43. The system of claim 42, wherein the logic is adapted to send the call information to the DMA gateway via the first interface according to routing instructions received at the DMA server from the DMA gateway.

24

- 44. The system of claim 42, wherein the logic is adapted to send the call information to the DMA gateway via the second interface according to routing instructions received at the DMA server from the DMA gateway.
- 45. The system of claim 42, wherein the logic is adapted to convert the call information to packet data when the call information is sent to the DMA gateway via the first interface.
