(57) ABSTRACT

A system, a method and computer-readable media for handling a device that experiences a failure to complete an authentication process of a network. The cause of the failure is determined. Authentication parameters that may be used by the device to complete the authentication process are then identified. The authentication parameters are communicated to the device, and the device is directed to reattempt the authentication process while utilizing the provided authentication parameters.

BACKGROUND

Recent developments in wireless telecommunications have ushered in a new era of mobility. The advent of cellular and personal communications services has enabled people to maintain communication from virtually any location. Further, advanced technology has facilitated not only wireless voice communication but also wireless data communication, such as the ability to communicate over computer networks and to send and receive data and other content.

Wireless communications systems have existed for many years. In general, a wireless communications system uses mobile or fixed radios that communicate with a fixed radio tower that is in turn interconnected to a larger telecommunications network. Such systems can take a variety of forms. For example, traditional cellular communications systems provide radio coverage to a wide area, such as a city, through use of many radio towers. Typically, subscribers to wireless service are equipped with one or more wireless terminals or "client devices," which may take any of a variety of forms. By way of example, a wireless client device may be a telephone, a pager, a computer, a personal digital assistant ("PDA") or any combination of these or other devices. A wireless client device may be configured to receive and/or convey information such as voice and data (e.g., fax, e-mail and other text messages) and/or other media (e.g., audio, video and graphics). Further, the client device may include input and output facilities such as a touch-pad, a keyboard, a camera, a display, a microphone and/or a speaker. Some client devices are equipped with web browsing software to allow subscribers to communicate with web servers over an Internet Protocol (IP) network (i.e., the Internet).

Wireless networks and mobile wireless devices may use a number of channels to transmit and receive information, and a properly equipped wireless device can initiate communications by sending an initiation request message over one of these channels. Applying industry standards, the initiation request message may include a code that characterizes the requested communication as packet-data communication, as compared with traditional voice communication.

With the rapid growth in the area of wireless communications, a variety of different access technologies has emerged. For example, Code Division Multiple Access (CDMA) is a packet-based wireless-access technology that may be used in certain cellular phone systems. As another example, Wi-Fi is an access technology based on a series of specifications from the Institute of Electrical and Electronics Engineers (IEEE) called 802.11. Wi-Fi uses radio frequency and enables a wireless-enabled computer or PDA to connect to the Internet via a wireless access point. Yet another access technology being utilized today is commonly referred to as WiMax (Worldwide Interoperability for Microwave Access). WiMax, also known as the IEEE 802.16 group of standards, defines a packet-based

2

wireless technology that provides high-throughput broadband connections over long distances.

Regardless of the access technologies in use, wireless network providers today require client devices to successfully negotiate strict authentication and access procedures before a device is granted network access. With these strict procedures, any failure during the authentication process will prevent the device from connecting to the network. A failure to complete network access and authentication, however, may not necessarily mean the user should be denied network access. While failures may occur for numerous different reasons, authentication services today do not evaluate the reason for a failed authentication or provide flexibility during the authentication process. As such, a failed authentication may lead to the loss of a potential wireless customer and/or the loss of revenue from a user session. Accordingly, there is a need for improved authentication and access procedures that provides secure, controlled and revenue generating connectivity to as many mobile devices as possible, including to devices that initially fail to properly connect to the network.

SUMMARY

The present invention provides systems and methods for handling a device that experiences a failure to complete an authentication process of a network. In one aspect of an embodiment of the present invention, a computer-implemented method is provided. The cause of the failure is determined. Authentication parameters that may be used by the device to complete the authentication process are then identified. The authentication parameters are communicated to the device, and the device is directed to reattempt the authentication process while utilizing the provided authentication parameters.

In another aspect of an embodiment of the present invention, a system is provided for authenticating devices attempting to access a network. The system includes a standard authentication component configured to provide a standard authentication process to be attempted by the devices. Devices that pass the standard authentication process are granted network access by the standard authentication component. The system also includes an account activation component configured to provide authentication parameters to a portion of the devices that fail the standard authentication process. Such devices are then directed to reattempt the standard authentication process while using the provided authentication parameters. A revenue-source assignment component is also included. This component is configured to grant network access to devices that fail the standard authentication process, while identifying entities to be billed for network usage associated these devices.

In yet another aspect of an embodiment of the present invention, a method is provided for handling devices that fail to complete a network's authentication process. The method searches for agreements committing one or more entities to be billed for network usage associated with a portion of the devices. Devices capable of presenting advertisements from advertisers are identified. Ultimately, network access is granted to at least a portion of the devices.

It should be noted that this Summary is provided to generally introduce the reader to one or more select concepts described below in the Detailed Description in a simplified form. This Summary is not intended to identify key and/or required features of the claimed subject matter, nor is it intended to be used as an aid in determining the scope of the claimed subject matter.

BRIEF DESCRIPTION OF THE SEVERAL
VIEWS OF THE DRAWING

The present invention is described in detail below with reference to the attached drawing figures, wherein:

FIG. 1 is a block diagram of a network environment suitable for use in implementing the present invention;

FIGS. 2A and 2B illustrate a method in accordance with one embodiment of the present invention for handling access/authentication failures;

FIG. 3 illustrates a method in accordance with one embodiment of the present invention for handling a device's failure to connect to a network;

FIGS. 4A-4C illustrate a method in accordance with one embodiment of the present invention for handling the authentication of a mobile device;

FIGS. 5A-5C illustrate a method in accordance with one embodiment of the present invention for handling the authentication of a user;

FIG. 6 illustrates a method in accordance with one embodiment of the present invention for facilitating initiation of an IP session;

FIG. 7 illustrates a method in accordance with one embodiment of the present invention for finding a revenue source to be billed for a device's network usage; and

FIG. 8 illustrates a method in accordance with one embodiment of the present invention for validating a MAC address.

DETAILED DESCRIPTION

The subject matter of the present invention is described with specificity to meet statutory requirements. However, the description itself is not intended to limit the scope of this patent. Rather, the inventors have contemplated that the claimed subject matter might also be embodied in other ways, to include different steps or combinations of steps similar to the ones described in this document, in conjunction with other present or future technologies. Moreover, although the term "step" may be used herein to connote different elements of methods employed, the term should not be interpreted as implying any particular order among or between various steps herein disclosed unless and except when the order of individual steps is explicitly described. Further, the present invention is described in detail below with reference to the attached drawing figures, which are incorporated in their entirety by reference herein.

The present invention provides an improved system and method for handling access/authentication failures. The invention may be described in the general context of computer-executable instructions, such as program modules, being executed by a computer. Generally, program modules include routines, programs, objects, components, data structures, etc., that perform particular tasks or implement particular abstract data types. Moreover, those skilled in the art will appreciate that the invention may be practiced with a variety of computer-system configurations, including multiprocessor systems, microprocessor-based or programmable-consumer electronics, minicomputers, mainframe computers, and the like. Any number of computer-systems and computer networks are acceptable for use with the present invention.

Specific hardware devices, programming languages, components, processes, and numerous details including operating environments and the like are set forth to provide a thorough understanding of the present invention. In other instances, structures, devices, and processes are shown in block-diagram form, rather than in detail, to avoid obscuring the present invention. But an ordinary-skilled artisan would

understand that the present invention may be practiced without these specific details. Computer systems, servers, work stations, and other machines may be connected to one another across a communication medium including, for example, a network or networks.

The invention may be practiced in distributed-computing environments where tasks are performed by remote-processing devices that are linked through a communications network. In a distributed-computing environment, program modules may be located in both local and remote computer-storage media including memory storage devices. The computer-useable instructions form an interface to allow a computer to react according to a source of input. The instructions cooperate with other code segments to initiate a variety of tasks in response to data received in conjunction with the source of the received data. Computer-readable media include both volatile and nonvolatile media, removable and nonremovable media, and contemplates media readable by a database, a switch, and various other network devices. Network switches, routers, and related components are conventional in nature, as are means of communicating with the same. By way of example, and not limitation, computer-readable media comprise computer-storage media and communications media.

The present invention may be embodied as, among other things: a method, system, computer-program product, or combinations thereof. Accordingly, the present invention may take the form of a hardware embodiment, a software embodiment, or an embodiment combining software and hardware. In one embodiment, the present invention takes the form of a computer-program product that includes computer-useable instructions embodied on one or more computer-readable media.

The present invention may be practiced in any network environment such as a communications network. Such networks are widely used to connect various types of network elements, such as routers, servers, gateways, network telephones, and so forth. Further, the invention may be practiced in a multi-network environment having various, connected public and/or private networks. The networks may be wireless or wireline ("wired"). As will be appreciated by those skilled in the art, communication networks may take several of different forms and may use several different communication protocols.

FIG. 1 illustrates a network environment **100** that represents an exemplary environment in which the present invention may be practiced. It is important to note that network environments in which the present invention may operate may be arranged in a variety of configurations, and the network environment **100** of FIG. 1 provides only one exemplary network environment.

The network environment **100** includes an IP core network **102**. The network **102** may be any network or combination of networks configured to provide communications between network devices. The network **102** provides communication services for clients **104A-104C**. The clients **104A-104C** may be any computing devices connected to the network **102**, and each of the clients **104A-104C** may have an address, such as an Internet protocol (IP) address, for uniquely identifying that client. The clients **104A-104C** may interact with the network **102** to receive a variety of content such as voice, data or video.

The network environment **100** may also include a wireless communication system configured to provide communication services to mobile clients **106A-106F**. In an exemplary wireless communication system, each mobile client **106A-106F** may communicate via an air interface with a base transceiver station **108A** or a base transceiver station **108B**. The

5

base transceiver stations **108A** and **108B** may be coupled to any number of different devices that enable connectivity with the network **102**, the public Internet and/or a private intranet (e.g., a wireless carrier's core network). The base transceiver stations **108A** and **108B** may utilize any number of wireless access technologies or standards known in the art to communicate with the mobile clients **106A-106F**.

In order to facilitate communication sessions originating from the mobile clients **106A-106F**, the network environment **100** includes a gateway **112**. As known to those skilled in the art, the gateway **112** may provide a variety of functions allowing clients to communicate with the IP core network **102**. Such functions may vary based on the type of access technology being utilized by an originating client device. The gateway **112** may receive communication requests from the mobile clients **106A-106F**, authenticate the clients and assign IP addresses.

FIG. 2 illustrates a method **200** for handling access/authentication failures. The method **200** includes steps **202**, **204**, **206** and **208**. These steps represent a process for network authentication in which a Mobile IP session is initiated. When a client device is turned on or enters an area with wireless network coverage, the device may attempt to access the wireless network by communicating with a local base station. It should be noted that the client device may be one of any number of devices capable of communicating wirelessly over an air interface, and the device may include applications that run on the device. For example, the applications may include a browsing application, such as a Wireless Application Protocol (WAP) browser. When initiated, the browser may receive content from a host device via the Internet (or other IP network).

To receive such content, the device must first be granted access to the network by successfully completing the steps **202**, **204**, **206** and **208**. The step **202** relates to network access, i.e., establishing a communication link between the device and the network. This step typically involves ensuring that the device has the proper hardware to communicate with the network, as well as authenticating/validating the device's identification information. Once the device has established a link to the network, the device and the user must be authenticated at the steps **204** and **206**. In one embodiment, the device and the network engage in signaling in accordance with the Extensible Authentication Protocol (EAP). As known to those skilled in the art, EAP is a universal authentication framework that provides some common functions and for negotiation of a desired authentication mechanism. Such mechanisms are called EAP methods, and there are currently about 40 different EAP methods in existence. Generally, the network will propose one or more EAP methods to be used to authenticate the device and/or the user. If the device supports the proposed method, the authentication process may proceed. Once the device and the user are authenticated, a Mobile IP session is established at the step **208**. With this connectivity, the device may access and interact with the network and other networked devices.

While the steps **202**, **204**, **206** and **208** represent the preferred steps of an authentication process, the steps **252**, **254** and **256** represent the steps taken by the method **200** in the event of an access/authentication failure. For example, if the device fails the device authentication at the step **204**, the method **200** seeks to determine the cause of the failure at the step **252**. Once the cause is established, a course of action may be determined at the step **254**. As will be explained in greater detail, this course of action may involve gathering more information about the client device and assessing the device's capabilities. At the step **256**, actions are performed with

6

respect to the client device, as dictated by the course of action determined at the step **254**. These actions may, for example, involve passing activation parameters to the device and/or locating a source of revenue to be associated with the device's IP sessions. So, instead of simply denying a device access when it fails to authenticate, the method **200** provides a "safety net" that attempts to diagnose the reasons for a failure and to take actions that provide at least some network access to the device.

FIG. 3 illustrates a method **300** in accordance with one embodiment of the present invention for handling a device's failure to connect to the network. For example, a device may fail to provide a valid or authorized Media Access Control address (MAC address). Unless the provided MAC address has been blacklisted, the method **300**, at a step **302**, determines whether the device has a device ID (e.g., an Network Access Identifier (NAI)). If such an ID is present, the method **300** allows the device to connect to the network at a step **304**. In one embodiment, an access control, policy enforcement and auditing framework may be utilized at the step **304** in connection with the grant of network connectivity. At a step **306**, the device may proceed to device authentication.

In event the device does not have a device ID, device attributes are obtained from a database based on the MAC address at a step **308**. In one embodiment, a global registry of devices may be maintained. Using a device ID and/or MAC address, this registry may allow various device capability parameters to be obtained. For example, the registry may store parameters such as the device's make, model, EAP capabilities, credentials and provisioning capabilities. Further, the registry may indicate whether the device supports audio or video advertisement pushes and/or HTTP/HTTPS.

Using the received device attributes, the method **300**, at a step **310**, determines whether the device can be provisioned with a device ID. If so, the device is provisioned with an ID (e.g., MAC@networkprovider.com) at a step **312**. A determination is made at a step **314** whether the provisioning was successful. If so, at a step **316**, the device is directed to reattempt authentication using the new device ID.

In the that event the device could not be provisioned or that the provisioning failed, the method **300**, at a step **318**, attempts to find a source of revenue to be associated with the device's network usage. For example, a bill-back agreement may exist between the device vender and the network service provider. Under such an agreement, the vender may be billed for the network usage costs. Alternately, the device may support advertisement pushes. In this case, the advertisers will pay for the device's network access. As another example, if the device is HTTP or WAP capable, the user may be pushed to a portal in which the user can enter payment information, such as a credit card number. Those skilled in the art will appreciate that any number of revenue sources may be associated with a user's session.

FIGS. 4A-4C illustrate a method **400** in accordance with one embodiment of the present invention for handling authentication of a device. At a step **402**, a preferred EAP method is proposed to the device. If a negative acknowledgement ("a NAK") is received at a step **404**, the method **400** proceeds to a reference numeral "A" on FIG. 4B. Otherwise, the device attempts to authenticate using the proposed EAP method at a step **406**. If this authentication succeeds, the method **400** allows the authentication process to proceed to user authentication at a step **408**.

In the event the device fails to authenticate at the step **406**, device attributes are obtained from a database at a step **410**. As previously mentioned, a global registry of devices may be maintained, and this registry may allow various device capa-

bility parameters to be obtained using the device's ID or MAC address. At a step **412**, the method **400** determines whether the device has credentials. If not, the method proceeds to a reference numeral "B" on FIG. **4C**.

At a step **414**, it is determined whether the hardware address matches the credentials. If there is a mismatch, this indicates fraud, and a fraud alert is signaled at a step **416**. As known to those skilled in the art, any number of measures may be taken in the event of detected fraud. To this end, the method **400** blacklists the device's MAC address at a step **418** and denies it network access.

If the hardware address matches the credentials, the device's credentials are used to propose device authentication at a step **420**. The method **400**, at a step **422**, determines whether or not this authentication was successful. If so, the device is allowed to proceed to user authentication at a step **424**. In the case of failure, the method **400** proceeds to the reference numeral "B" on FIG. **4C**.

FIG. **4B** illustrates the steps of the method **400** that are performed when the device does not support the EAP method initially proposed by the network. At a step **440**, it is determined whether a different preferred EAP method was proposed in the NAK. If not, the method **400** proceeds to the reference numeral "B" on FIG. **4C**. If an EAP method was present in the NAK, the method **400**, at a step **442**, proposes the use of this EAP method for device authentication. At a step **444**, it is determined whether authentication using the proposed EAP method succeeded. In the event of failure, the method **400** proceeds to the reference numeral "B" on FIG. **4C**. Otherwise, upon a successful authentication, the method **400**, at a step **446**, determines whether the user was authenticated via the preferred EAP method. Depending on this determination, the authentication either proceeds to IP session setup at a step **448** or to user authentication at a step **450**.

Turning to FIG. **4C**, device attributes are obtained from a database (e.g., a global registry of devices) at a step **470**. For example, these attributes may indicate whether the device is capable of accepting X.509 certificate provisioning and/or EAP provisioning. At a step **472**, the method **400** determines whether the device accepts provisioning. If not, the method **400**, at a step **474**, either finds a source of revenue to be associated with the device's network usage or denies network access to the device.

If it is determined that the device can accept provisioning, the device is activated with the correct parameters at a step **476**. In one embodiment, this activation entails attempting to setup a user account for the device, provisioning the device to perform a normalized EAP method and/or pushing an X.509 certificate to the device. As will be appreciated by those skilled in the art, a provisionable device may be configured to allow successfully authentication via a standard authentication process. To this end, the device is directed to reinitiate the standard authentication process at a step **478**. Using its newly-provided parameters, the device may likely pass the standard process.

FIGS. **5A-5C** illustrate a method **500** in accordance with one embodiment of the present invention for handling authentication of a user. At a step **502**, a preferred user EAP method is proposed to the device. If a NAK is received at a step **504**, the method **500** proceeds to a reference numeral "A" on FIG. **5B**. Otherwise, user authentication using the proposed EAP method is attempted at a step **506**. The method **500** determines whether this authentication succeeded at a step **508**. If so, the method **500** allows the authentication process to proceed to Mobile IP setup at a step **510**.

In the event that the user authentication failed at the step **508**, it is determined, at a step **512**, whether the authentication

was even attempted. If there was no attempted authentication, the method **500** sends a Foreign Agent (FA) advertisement with an FA challenge. As known to those in the art, the FA is configured to issue a router advertisement, which includes an FA challenge. The mobile device extracts the challenge from the advertisement and computes a response. This response may be in the form of a Mobile IP Registration Request (MIP RRQ). As such, it is determined at a step **516** whether a MIP RRQ was received in response to the FA advertisement. If not, the method **500** proceeds to a reference numeral "B" on FIG. **5C**. Alternately, when a MIP RRQ is received, the method **500** determines whether the user was successfully authenticated at a step **518**. If so, the method **500** facilitates initiation of a Mobile IP session at a step **520**.

In the event that the user failed to be authenticated at the step **518**, device attributes are obtained from a database at a step **524**. Similarly, in the event that no user authentication was attempted at the step **512**, the device attributes are obtained from a database at a step **522**. In both cases, the method **500** proceeds to a reference numeral "C" on FIG. **5C**.

FIG. **5B** illustrates the steps of the method **500** that are performed when the user device does not support the user EAP method initially proposed by the network. At a step **540**, it is determined whether a different preferred EAP method was proposed in the NAK. If not, the method **500** proceeds to the reference numeral "B" on FIG. **5C**. If an EAP method was present in the NAK, the method **500** proposes the use of this EAP for user authentication at a step **542**. At a step **544**, it is determined whether user authentication using the proposed EAP method succeeded. In the event of failure, the method **500** proceeds to the reference numeral "B" on FIG. **5C**. Upon a successful authentication, however, the method **500**, at a step **546**, proceeds to IP session setup at a step **546**.

Turning to FIG. **5C**, device attributes are obtained from a database (e.g., the global registry of devices) at a step **560**. At a step **562**, the method **500** determines whether the device accepts provisioning. If not, the method **500**, at a step **564**, either finds a source of revenue to be associated with the device's network usage or denies network access to the device. If it is determined that the device can accept provisioning, the device is activated with the correct parameters at a step **566**. As previously mentioned, this activation may attempt to setup a user account for the device, to enable the device to perform a normalized EAP method and/or to push an X.509 certificate to the device. Finally, at a step **568**, the device is directed to reinitiate the standard authentication process using the correct parameters.

FIG. **6** illustrates a method **600** in accordance with one embodiment of the present invention for facilitating initiation of an IP session. At a step **602**, it is determined whether a Dynamic Host Configuration Protocol (DHCP) request was received. As known to those in the art, DHCP is an Internet protocol for automating the configuration of computers that use TCP/IP. If no request was received at the step **602**, an FA advertisement is sent at a step **604** without an FA challenge. Subsequently, the method **600** facilitates initiation of a Mobile IP session at a step **606**.

In the event that a DHCP request was received at the step **602**, it is determined at a step **608** whether a Proxy Mobile IP (PMIP) key was successfully negotiated. If so, a proxy is used for the Mobile IP registration at a step **610**. At a step **612**, a home address (HoA) is assigned to the device via DHCP, and the method **600** facilitates initiation of a Proxy Mobile IP session at a step **614**. In the event that a PMIP key was not negotiated at the step **608**, an IP address is assigned to the device from the locate IP pool via DHCP at a step **616**. Then, the method **600** facilitates a Simple IP session at a step **618**.

FIG. 7 illustrates a method **700** in accordance with one embodiment of the present invention for finding a revenue source to be billed for a device's network usage. At a step **702**, the device is assigned an IP address, which is pushed via DHCP. At a step **704**, it is determined whether there exists a bill-back agreement with a device vender. For example, the vender and the network provider may have a contract in which the vender agrees to pay for usage associated with their devices. If such an agreement is in place, the method **700** grants the device full network access at a step **706**. At a step **708**, the vender is billed for the usage.

In the absence of a bill-back agreement, the method **700**, at a step **710**, determines whether the device is able to receive audio and/or video content. If so, the device is granted full network access at a step **712**. Subsequently, advertisements may be pushed to the device at a step **714**. Thereafter, advertisers will be billed for the network usage associated with the user's session.

If the device cannot receive audio or video, it is determined to a step **716** whether the device is HTTP or WAP capable. If so, the device is directed to a provisioning portal at a step **718**. For example, the user may be presented a web page in which a credit card number may be entered to pay for any network usage. In this example, usage charges may be applied to the user's credit card at the end of the session.

If the device is not HTTP or WAP capable, the method **700** proceeds to the step **720**. While the method **700** evaluates a number of potential revenue sources, network access is denied at the step **720** in the absence of an identified revenues source, and the device is disconnected from the network.

FIG. 8 illustrates a method **800** in accordance with one embodiment of the present invention for validating a MAC address. For example, a network provider may wish to validate a device's MAC address at the beginning of the authentication process. At a step **802**, the MAC address is obtained from the device. This MAC address may then be used in the querying of a database. In one embodiment, a database of blacklisted MAC addresses may be maintained, and MAC addresses may be blacklisted for fraud or previous failed authentications attempts. By maintaining a database of such addresses, the method **800** may quickly recognize devices that should not be granted network access.

At a step **806**, it is determined whether the device's MAC address was found in the database. If so, the device is denied access, and the authentication process terminates at a step **808**. Alternately, when there is no record of the MAC address in the database, the authentication process is allowed to proceed at a step **810**.

Alternative embodiments and implementations of the present invention will become apparent to those skilled in the

art to which it pertains upon review of the specification, including the drawing figures. Accordingly, the scope of the present invention is defined by the appended claims rather than the foregoing description.

The invention claimed is:

1. One or more non-transitory computer-readable media having computer-useable instructions embodied thereon to perform a method for handling devices that fail to complete an authentication process of a network, the method comprising: incident to detecting one or more failures to complete the authentication process, identifying one or more alternative authentication processes, wherein said one or more alternative authentication processes do not require user intervention; reattempting, without user intervention, to authenticate a plurality of devices by utilizing said one or more alternative authentication processes; incident to success in completing authentication via said one or more alternative authentication processes, identifying one or more entities to be billed for network usage associated with at least a portion of the plurality of devices authenticated via said one or more alternative authentication processes, said identifying comprising: searching for one or more agreements committing one or more entities to be billed for network usage associated with at least a portion of the plurality of devices; identifying whether at least a portion of said plurality of devices are capable of presenting advertisements from one or more advertisers; and directing at least a portion of said plurality of devices to a portal capable of receiving payment information from users; granting network access to at least a portion of said devices associated with one or more entities to be billed for network usage.

2. The media of claim 1, wherein said method further comprises billing said one or more entities for network usage associated with at least a portion of the devices.

3. The media of claim 1, wherein said method further comprises presenting advertisements on at least a portion of said devices.

4. The media of claim 3, wherein said method further comprises billing said one or more advertisers for network usage associated with at least a portion of the devices.

5. The media of claim 1, wherein said method further comprises denying network access to one or more of the devices that lack an entity to be billed for network usage.

6. The media of claim 1, wherein said method further comprises preventing devices that lack an entity to be billed for network usage from re-attempting said authentication process.

7. The media of claim 1, wherein said network is a WiMax network.
