## COMPOSITIONS AND PROCESSES FOR IMMERSION LITHOGRAPHY

The present invention relates to new photoresist compositions that are particularly useful in immersion lithography processes. Preferred photoresist compositions of the invention comprises two or more materials that can be substantially non-mixable with a resin component of the resist. Particularly preferred photoresists of the invention can exhibit reduced leaching of resist materials into an immersion fluid contacting the resist layer during immersion lithography processing.

Photoresists are photosensitive films used for transfer of an image to a substrate. A coating layer of a photoresist is formed on a substrate and the photoresist layer is then exposed through a photomask to a source of activating radiation. The photomask has areas that are opaque to activating radiation and other areas that are transparent to activating radiation. Exposure to activating radiation provides a photoinduced chemical transformation of the photoresist coating to thereby transfer the pattern of the photomask to the photoresist coated substrate. Following exposure, the photoresist is developed to provide a relief image that permits selective processing of a substrate.

The growth of the semiconductor industry is driven by Moore's law which states that the complexity of an IC device doubles on average every two years. This necessitates the need to lithographically transfer patterns and structures with ever decreasing feature size.

One approach to achieving smaller feature sizes is to use shorter wavelengths of light, however, the difficulty in finding materials that are transparent below 193 nm has led to the option of using immersion lithography to increase the numerical aperture of the lens by simply using a liquid to focus more light into the film. Immersion lithography employs a relatively high refractive index fluid between the last surface of an imaging device (e.g., KrF or ArF stepper) and the first surface on a wafer or other substrate.

Certain efforts have been made to address problems associated with immersion lithography. See U.S. Patent Application Publication 2006/0246373. Additional reliable and convenient photoresist and imaging processes for immersion lithography are clearly needed.

It would be desirable to new materials and processes for immersion photolithography.

We now provide new compositions and processes for immersion photolithography.

Preferred photoresists of the invention may comprise:

- (i) one or more resins,
- (ii) a photoactive component which may suitably comprise one or more photoacid generator compounds, and
- (iii) two or more distinct materials that are substantially non-mixable with the one or more resins.

Of such photoresist compositions preferred are chemically-amplified positive-acting resists, e.g. where the resin component comprises one or more resins comprising photoacid-labile groups such as photoacid-labile ester or acetal groups.

The substantially non-mixable component of such photoresist compositions suitably comprises at least two distinct materials. Those distinct materials sometimes may be referred to herein as a "top material" and "intermediate material". Preferred top and intermediate materials are polymers (resins) which may suitably differ by at least one polymer repeat unit.

In preferred systems, the top material and intermediate material also differ in hydrophobicity, particularly where the top material is more hydrophobic than the intermediate mate-

rial. Thus, for example, the intermediate material may contain more polar groups (relative to the top material) to the polar group where such polar groups may suitably contain one or more hetero atoms (O, N, S) such as hydroxy, haloalcohol (e.g.  $-\text{CH}(\text{OH})(\text{CF}_3)_2$ ), carboxy ( $-\text{COOH}$ ), ester ( $-\text{C}(=\text{O})\text{OR}$  where R is  $\text{C}_{1-20}$  alkyl), sulfono ( $-\text{SO}_3\text{H}$ ), and ether. For instance, the top material and intermediate material by be the same general resins, except one repeat unit of the intermediate material may contain haloalcohol (e.g.  $-\text{CH}(\text{OH})(\text{CF}_3)_2$ ) substitution whereas the corresponding unit of the top material does not contain such haloalcohol substitution.

In additional preferred systems, the intermediate material also may differ in hydrophobicity relative to the resin component of the photoresist composition, particularly where the intermediate material is more hydrophobic than the resin component (again, in chemically-amplified positive-acting resists, the resin component comprises one or more resins that comprise photoacid-labile groups). Thus, for instance, the one or more resins may comprise more (relative to the intermediate material as well as the top material) polar groups such as ester or acetal groups (which may be photoactive) or other polar groups which may suitably contain one or more hetero atoms (O, N, S) such as hydroxy, haloalcohol (e.g.  $-\text{CH}(\text{OH})(\text{CF}_3)_2$ ), carboxy ( $-\text{COOH}$ ), sulfono ( $-\text{SO}_3\text{H}$ ), and ether.

In such preferred photoresist systems, in addition to differences in hydrophobicity, preferably the surface energy of the top material is greater than the surface energy of the intermediate material. Further preferred is where the surface energy of the intermediate material is greater than the surface energy of the resin component (again, in chemically-amplified positive-acting resists, the resin component comprises one or more resins that comprise photoacid-labile groups). For instance, the surface energy between the top material and the intermediate material may differ by at least about 5, 10, 15, 20 or 25 dynes/cm. Similarly, the surface energy between the intermediate material and the resin component may differ by at least about 5, 10, 15, 20 or 25 dynes/cm.

In such preferred systems, by such differences in hydrophobicity and surface energy, a spin-coated layer of the photoresist composition may adapt a graded configuration, wherein a substantial portion of the resin component (again, in chemically-amplified positive-acting resists, the resin component comprises one or more resins that comprise photoacid-labile groups) will be closer to the underlying substrate surface relative to the intermediate and top materials, and a substantial portion of the intermediate material will be closer to the underlying substrate surface than the top material in the photoresist composition layer. References to "substantial portion(s)" of a top material, intermediate material or resin component herein are intended to indicate at least 30, 40, 50, 60 or 70 weight percent of that material or component, based on total weight of that material or component in the photoresist composition.

Particularly preferred photoresists of the invention can exhibit reduced migration (leaching) of photoresist components into the immersion fluid during contact of the immersion fluid during an exposure step. Significantly, such reduced migration of photoresist materials into immersion fluid can be achieved without applying any type of cover or barrier layer over the photoresist and interposed between the resist layer and immersion fluid.

We have found that undesired migration of acid and/or other resist materials from a photoresist layer into the immersion fluid layer can be particularly problematic. Among other things, the acid or other photoresist materials that migrate into the immersion fluid can damage the exposure tool as well as

reduce resolution of an image patterned into a photoresist layer. Accordingly, the photoresists of the invention constitute a significant advance.

Without being bound by any theory, it is believed the two or more distinct materials that are substantially non-mixable with the one or more resist resins can migrate toward upper regions of an applied photoresist coating layer and thereby inhibit migration of photoresist materials out of a resist layer into immersion fluid that contacts the resist layer during an immersion exposure step.

Additionally, by use of multiple non-mixable materials, it is possible to control multiple lithographic properties of a photoresist composition. For instance, the top material of a photoresist composition can provide an optimal water contact angle to facilitate interactions with overcoating fluid in an immersion lithography process. The intermediate material then can serve as a primary barrier to avoid leaching. The use of the two distinct materials (i.e. top and intermediate materials) together also can provide more effective control of undesired leaching of photoresist component(s) into overcoating immersion fluid.

As referred to herein, materials that are substantially non-mixable with the one or more photoresist resins include those materials added to a photoresist that results in reduced migration or leaching of photoresist materials into immersion fluid. Such substantially non-mixable materials can be readily identified empirically by testing relative to a control resist that has the same components as the tested photoresist, but not the candidate substantially non-mixable material(s).

Suitable substantially non-mixable materials for use in photoresists of the invention include compositions that comprise silicon and/or fluorine substitution.

Preferred substantially non-mixable materials for use in photoresists of the invention may be in the form of particles. Such particles may include polymers that are polymerized in the form discrete particles, i.e. as separate and distinct polymer particles. Such polymer particles typically have one or more different characteristics from linear or ladder polymers such as linear or ladder silicon polymers. For example, such polymer particles may have a defined size and a low molecular weight distribution. More particularly, in a preferred aspect, a plurality of the polymer particles may be employed in a photoresist of the invention with a mean particle size (dimension) of from about 5 to 3000 angstroms, more preferably from about 5 to 2000 angstroms, still more preferably from about 5 to about 1000 angstroms, yet more preferably from about 10 to about 500 angstroms, even more preferably from 10 to 50 or 200 angstroms. For many applications, particularly preferred particles have a mean particle size of less than about 200 or 100 angstroms.

Additional preferred substantially non-mixable materials for use in photoresists of the invention may have Si content, including silsesquioxane materials, materials with SiO<sub>2</sub> groups, and the like. Preferred silicon-containing substantially non-mixable materials also include polyhedral oligomeric silsesquioxanes.

Also preferred are those substantially non-mixable materials that contain photoacid-labile groups, such as photoacid-labile ester or acetal groups, including such groups as described herein employed in a resin component of a chemically amplified photoresist.

Preferred substantially non-mixable materials for use in photoresists of the invention also will be soluble in the same organic solvent(s) used to formulate the photoresist composition.

Particularly preferred substantially non-mixable materials for use in photoresists of the invention also will have lower

surface energy and/or smaller hydrodynamic volume than the one or more resins of the photoresist's resin component. The lower surface energy can facilitate segregation or migration of the substantially non-mixable materials to top or upper portions of an applied the photoresist coating layer. Additionally, relative smaller higher hydrodynamic volume also can be preferred because it can facilitate efficient migration (higher diffusion coefficient) of the one or more substantially non-mixable materials to upper regions of the applied photoresist coating layer.

Preferred substantially non-mixable materials for use in photoresists of the invention also will be soluble in photoresist developer compositions (e.g. 0.26N aqueous alkaline solution). Thus, in addition to photoacid-labile groups as discussed above, other aqueous base-solubilizing groups may be included in the substantially non-mixable materials such as hydroxyl, fluoroalcohol, carboxy and the like.

Preferred imaging wavelengths of lithographic systems of the invention include sub-400 nm such as I-line (365 nm), sub-300 nm wavelengths e.g. 248 nm, and sub-200 nm wavelengths e.g. 193 nm. In addition to one or more substantially non-mixable materials, particularly preferred photoresists of the invention may contain a photoactive component (e.g. one or more photoacid generator compounds) and one or more resins that are chosen from among:

1) a phenolic resin that contains acid-labile groups that can provide a chemically amplified positive resist particularly suitable for imaging at 248 nm. Particularly preferred resins of this class include: i) polymers that contain polymerized units of a vinyl phenol and an alkyl acrylate, where the polymerized alkyl acrylate units can undergo a deblocking reaction in the presence of photoacid. Exemplary alkyl acrylates that can undergo a photoacid-induced deblocking reaction include e.g. t-butyl acrylate, t-butyl methacrylate, methyladamantyl acrylate, methyl adamantyl methacrylate, and other non-cyclic alkyl and alicyclic acrylates that can undergo a photoacid-induced reaction, such as polymers in U.S. Pat. Nos. 6,042,997 and 5,492,793, incorporated herein by reference; ii) polymers that contain polymerized units of a vinyl phenol, an optionally substituted vinyl phenyl (e.g. styrene) that does not contain a hydroxy or carboxy ring substituent, and an alkyl acrylate such as those deblocking groups described with polymers i) above, such as polymers described in U.S. Pat. No. 6,042,997, incorporated herein by reference; and iii) polymers that contain repeat units that comprise an acetal or ketal moiety that will react with photoacid, and optionally aromatic repeat units such as phenyl or phenolic groups; such polymers have been described in U.S. Pat. Nos. 5,929,176 and 6,090,526, incorporated herein by reference, as well as blends of i) and/or ii) and/or iii);

2) phenolic resins that do not contain acid-labile groups such as poly(vinylphenol) and novolak resins that may be employed in I-line and G-line photoresists together with a diazonaphthoquinone photoactive compound and have been described e.g. in U.S. Pat. Nos. 4,983,492; 5,130,410; 5,216,111; and 5,529,880;

3) a resin that is substantially or completely free of phenyl or other aromatic groups that can provide a chemically amplified positive resist particularly suitable for imaging at sub-200 nm wavelengths such as 193 nm. Particularly preferred resins of this class include: i) polymers that contain polymerized units of a non-aromatic cyclic olefin (endocyclic double bond) such as an optionally substituted norbornene, such as polymers described in U.S. Pat. Nos. 5,843,624, and 6,048,664, incorporated herein by reference; ii) polymers that contain alkyl acrylate units such as e.g. t-butyl acrylate, t-butyl methacrylate, methyladamantyl acrylate, methyl adamantyl

## 5

methacrylate, and other non-cyclic alkyl and alicyclic acrylates; such polymers have been described in U.S. Pat. No. 6,057,083; European Published Applications EP01008913A1 and EP00930542A1; and U.S. pending patent application Ser. No. 09/143,462, all incorporated herein by reference, and iii) polymers that contain polymerized anhydride units, particularly polymerized maleic anhydride and/or itaconic anhydride units, such as disclosed in European Published Application EP01008913A1 and U.S. Pat. No. 6,048,662, both incorporated herein by reference, as well as blends of i) and/or ii) and/or iii);

4) a resin that contains repeat units that contain a hetero atom, particularly oxygen and/or sulfur (but other than an anhydride, i.e. the unit does not contain a keto ring atom), and preferable are substantially or completely free of any aromatic units. Preferably, the heteroalicyclic unit is fused to the resin backbone, and further preferred is where the resin comprises a fused carbon alicyclic unit such as provided by polymerization of a norbornene group and/or an anhydride unit such as provided by polymerization of a maleic anhydride or itaconic anhydride. Such resins are disclosed in PCT/US01/14914 and U.S. application Ser. No. 09/567,634.

5) resins that contain Si-substitution including poly(silsequioxanes) and the like and may be used with an undercoated layer. Such resins are disclosed e.g. in U.S. Pat. No. 6,803,171.

6) a resin that contains fluorine substitution (fluoropolymer), e.g. as may be provided by polymerization of tetrafluoroethylene, a fluorinated aromatic group such as fluoro-styrene compound, compounds that comprise a hexafluoroalcohol moiety, and the like. Examples of such resins are disclosed e.g. in PCT/US99/21912.

Preferred photoresists of the invention include both chemically-amplified positive-acting and negative-acting photoresists. Typically preferred chemically-amplified positive resists include one or more resins that comprise photoacid-labile groups such as photoacid-labile ester or acetal groups.

The invention further provides methods for forming a photoresist relief image and producing an electronic device using photoresists of the invention. The invention also provides novel articles of manufacture comprising substrates coated with a photoresist composition of the invention.

Other aspects of the invention are disclosed infra.

FIG. 1 shows schematically a preferred photoresist composition layer of the invention.

We have found that addition of two or more distinct substantially non-mixable materials can improve lithographic performance of a photoresist.

Preferred photoresists of the invention comprises at least three distinct resins: a first resin that comprises photoacid labile groups and distinct second and third resins. Each of the resins preferably differ in hydrophobicity and surface energy as discussed above. Hydrophobicity and surface energy may be assessed by known methods. For example, U.S. Pat. No. 6,927,012 discloses methods for determination of surface energy of a material. Hydrophobicity of a material can be assessed by high performance liquid chromatographic methods. Each of the first resin that comprises photoacid labile groups and distinct second and third resins may have a molecular weight within a wide range, e.g. a Mw of from about 1,000 to 100,000, more typically an Mw of 1500 to 8,000, 10,000, 15,000, 20,000, 30,000, 40,000 or 50,000, with a polydispersity of about 4, 3 or 2 or less.

Referring to FIG. 1, there is shown a schematic of a preferred photoresist composition 10 that has been spin-coated onto a silicon wafer 12. The applied photoresist composition layer has been soft-baked (e.g. 105° C. for 60 seconds) to

## 6

remove solvent. As shown in FIG. 1, materials of the photoresist can segregate into differing regions, i.e. wherein the one or more resins with photoacid labile groups substantially reside in area 14 closest to the surface of substrate 12, followed by the intermediate material (e.g. terpolymer with hexafluoroalcohol and carboxy groups) which may substantially reside in the depicted intermediate region 16, and then top polymer (e.g. copolymer with less polar groups than the intermediate material) which may substantially reside in the depicted top region 18.

As discussed above, suitable materials of photoresists of the invention that are substantially non-mixable with the resist resin component can be readily identified by simple testing. In particular, as referred to herein, preferred substantially non-mixable materials will provide a decreased amount of acid or organic material to be detected in the immersion fluid upon use of the photoresist composition containing the candidate material relative to the same photoresist system that is processed into the same manner, but in the absence of the candidate substantially non-mixable material(s). Detection of photoresist material in the immersion fluid can be conducted as described in Example 2 which follows and includes mass spectroscopy analysis of the immersion fluid before and after exposure to the photoresist. In such analysis, the immersion fluid directly contacts the tested photoresist composition layer for about 60 seconds during exposure. Preferably, addition of one or more substantially non-mixable materials provides at least a 10 percent reduction in photoresist material (again, acid or organics as detected by mass spectroscopy) residing in the immersion fluid relative to the same photoresist that does not employ such substantially non-mixable material(s), more preferably the one or more substantially non-mixable materials provides at least a 20, 50, or 100, 200, 500, or 1000 percent reduction photoresist material (again, acid and/or organics) residing in to the immersion fluid relative to the same photoresist that does not contain the substantially non-mixable material(s).

As discussed above, specifically preferred substantially non-mixable materials include Si-containing materials. Especially preferred substantially non-mixable materials include nanostructured compositions, which are commercially available from groups such as Hybrid Plastics (Fountain Valley, Calif.), Sigma/Aldrich, and others. Such materials may include molecular silicas which have a Si—O core enveloped by organic groups; silanols; and polymers and resins which include silsesquioxane cage-structured compounds and may be silicones, styrenics, acrylics, alicyclics such as norbornenes and others.

Particles (including organic particles) useful as substantially non-mixable materials include Si-containing and fluorinated materials. Such particles are commercially available, or can be readily synthesized, e.g. by reaction of one or more monomers together with a crosslinking agent and an initiator compound if desired. The reacted monomers may have substitution as desired e.g. fluorine, Si groups, photoacid-labile groups such as photoacid-labile esters or acetals, other base-solubilizing groups such as alcohols and the like. See Example 1 which follows for an exemplary synthesis of such particles produced with multiple distinct monomers, where one of the monomers provides a photoacid-labile group to the resulting polymer particle.

The substantially non-mixable material(s) may be present in a photoresist composition in relatively small amounts and still provide effective results. For instance, the one or more substantially non-mixable materials may be suitable present in about 0.1 to 20 weight percent based on total weight of a

fluid photoresist composition. Suitable amounts also are provided in the examples which follow.

As discussed above, preferred photoresists for use in accordance with the invention include positive-acting or negative-acting chemically amplified photoresists, i.e. negative-acting resist compositions which undergo a photoacid-promoted crosslinking reaction to render exposed regions of a coating layer of the resist less developer soluble than unexposed regions, and positive-acting resist compositions which undergo a photoacid-promoted deprotection reaction of acid labile groups of one or more composition components to render exposed regions of a coating layer of the resist more soluble in an aqueous developer than unexposed regions. Ester groups that contain a tertiary non-cyclic alkyl carbon (e.g. t-butyl) or a tertiary alicyclic carbon (e.g. methyladamantyl) covalently linked to the carboxyl oxygen of the ester are often preferred photoacid-labile groups of resins employed in photoresists of the invention. Acetal photoacid-labile groups also will be preferred.

Preferred photoresists of the invention typically comprise a resin component and a photoactive component. Preferably the resin has functional groups that impart alkaline aqueous developability to the resist composition. For example, preferred are resin binders that comprise polar functional groups such as hydroxyl or carboxylate. Preferably a resin component is used in a resist composition in an amount sufficient to render the resist developable with an aqueous alkaline solution.

For imaging at wavelengths greater than 200 nm, such as 248 nm, phenolic resins are typically preferred. Preferred phenolic resins are poly(vinylphenols) which may be formed by block polymerization, emulsion polymerization or solution polymerization of the corresponding monomers in the presence of a catalyst. Vinylphenols useful for the production of polyvinyl phenol resins may be prepared, for example, by hydrolysis of commercially available coumarin or substituted coumarin, followed by decarboxylation of the resulting hydroxy cinnamic acids. Useful vinylphenols may also be prepared by dehydration of the corresponding hydroxy alkyl phenols or by decarboxylation of hydroxy cinnamic acids resulting from the reaction of substituted or nonsubstituted hydroxybenzaldehydes with malonic acid. Preferred polyvinylphenol resins prepared from such vinylphenols have a molecular weight range of from about 2,000 to about 60,000 daltons.

Also preferred for imaging at wavelengths greater than 200 nm, such as 248 nm are chemically amplified photoresists that comprise in admixture a photoactive component and a resin component that comprises a copolymer containing both phenolic and non-phenolic units. For example, one preferred group of such copolymers has acid labile groups substantially, essentially or completely only on non-phenolic units of the copolymer, particularly alkylacrylate photoacid-labile groups, i.e. a phenolic-alkyl acrylate copolymer. One especially preferred copolymer binder has repeating units x and y of the following formula:

wherein the hydroxyl group be present at either the ortho, meta or para positions throughout the copolymer, and R' is substituted or unsubstituted alkyl having 1 to about 18 carbon atoms, more typically 1 to about 6 to 8 carbon atoms. Tert-butyl is a generally preferred R' group. An R' group may be optionally substituted by e.g. one or more halogen (particularly F, Cl or Br), C<sub>1-8</sub> alkoxy, C<sub>2-8</sub> alkenyl, etc. The units x and y may be regularly alternating in the copolymer, or may be randomly interspersed through the polymer. Such copolymers can be readily formed. For example, for resins of the above formula, vinyl phenols and a substituted or unsubstituted alkyl acrylate such as t-butylacrylate and the like may be condensed under free radical conditions as known in the art. The substituted ester moiety, i.e. R'—O—C(=O)—, moiety of the acrylate units serves as the acid labile groups of the resin and will undergo photoacid induced cleavage upon exposure of a coating layer of a photoresist containing the resin. Preferably the copolymer will have a M<sub>w</sub> of from about 8,000 to about 50,000, more preferably about 15,000 to about 30,000 with a molecular weight distribution of about 3 or less, more preferably a molecular weight distribution of about 2 or less. Non-phenolic resins, e.g. a copolymer of an alkyl acrylate such as t-butylacrylate or t-butylmethacrylate and a vinyl alicyclic such as a vinyl norbornanyl or vinyl cyclohexanol compound, also may be used as a resin binder in compositions of the invention. Such copolymers also may be prepared by such free radical polymerization or other known procedures and suitably will have a M<sub>w</sub> of from about 8,000 to about 50,000, and a molecular weight distribution of about 3 or less.

Other preferred resins that have acid-labile deblocking groups for use in a positive-acting chemically-amplified photoresist of the invention have been disclosed in European Patent Application 0829766A2 of the Shipley Company (resins with acetal and ketal resins) and European Patent Application EP0783136A2 of the Shipley Company (terpolymers and other copolymers including units of 1) styrene; 2) hydroxystyrene; and 3) acid labile groups, particularly alkyl acrylate acid labile groups such as t-butylacrylate or t-butylmethacrylate). In general, resins having a variety of acid labile groups will be suitable, such as acid sensitive esters, carbonates, ethers, imides, etc. The photoacid labile groups will more typically be pendant from a polymer backbone, although resins that have acid labile groups that are integral to the polymer backbone also may be employed.

As discussed above, for imaging at sub-200 nm wavelengths such as 193 nm, preferably a photoresist is employed that contains one or more polymers that are substantially, essentially or completely free of phenyl or other aromatic groups. For example, for sub-200 nm imaging, preferred photoresist polymers contain less than about 5 mole percent aromatic groups, more preferably less than about 1 or 2 mole percent aromatic groups, more preferably less than about 0.1, 0.02, 0.04 and 0.08 mole percent aromatic groups and still more preferably less than about 0.01 mole percent aromatic groups. Particularly preferred polymers are completely free of aromatic groups. Aromatic groups can be highly absorbing of sub-200 nm radiation and thus are undesirable for polymers used in photoresists imaged with such short wavelength radiation.

Suitable polymers that are substantially or completely free of aromatic groups and may be formulated with a PAG of the invention to provide a photoresist for sub-200 nm imaging are disclosed in European application EP930542A1 and U.S. Pat. Nos. 6,692,888 and 6,680,159, all of the Shipley Company.

Suitable polymers that are substantially or completely free of aromatic groups suitably contain acrylate units such as photoacid-labile acrylate units as may be provided by poly-

9

merization of methyladamantylacrylate, methyladamantylmethacrylate, ethylfenchylacrylate, ethylfenchylmethacrylate, and the like; fused non-aromatic alicyclic groups such as may be provided by polymerization of a norbornene compound or other alicyclic compound having an endocyclic carbon-carbon double bond; an anhydride such as may be provided by polymerization of maleic anhydride and/or itaconic anhydride; and the like.

Preferred negative-acting compositions of the invention comprise one or more materials (such as a crosslinker component e.g. an amine-based materials such as a melamine resin) that will cure, crosslink or harden upon exposure to acid, and a photoactive component of the invention. Particularly preferred negative acting compositions comprise a resin binder such as a phenolic resin, a crosslinker component and a photoactive component of the invention. Such compositions and the use thereof has been disclosed in European Patent Applications 0164248 and 0232972 and in U.S. Pat. No. 5,128,232 to Thackeray et al. Preferred phenolic resins for use as the resin binder component include novolaks and poly(vinylphenol)s such as those discussed above. Preferred crosslinkers include amine-based materials, including melamine, glycolurils, benzoguanamine-based materials and urea-based materials. Melamine-formaldehyde resins are generally most preferred. Such crosslinkers are commercially available, e.g. the melamine resins sold by American Cyanamid under the trade names Cymel 300, 301 and 303. Glycoluril resins are sold by American Cyanamid under trade names Cymel 1170, 1171, 1172, urea-based resins are sold under the trade names of Beetle 60, 65 and 80, and benzoguanamine resins are sold under the trade names Cymel 1123 and 1125.

For imaging at sub-200 nm wavelengths such as 193 nm, preferred negative-acting photoresists are disclosed in WO 03077029 to the Shipley Company.

Photoresists of the invention also may contain other materials. For example, other optional additives include actinic and contrast dyes, anti-striation agents, plasticizers, speed enhancers, sensitizers (e.g. for use of a PAG of the invention at longer wavelengths such as I-line (i.e. 365 nm) or G-line wavelengths), etc. Such optional additives typically will be present in minor concentration in a photoresist composition except for fillers and dyes which may be present in relatively large concentrations such as, e.g., in amounts of from 5 to 30 percent by weight of the total weight of a resist's dry components.

A preferred optional additive of resists of the invention is an added base, e.g. a caprolactam, which can enhance resolution of a developed resist relief image. The added base is suitably used in relatively small amounts, e.g. about 1 to 10 percent by weight relative to the PAG, more typically 1 to about 5 weight percent. Other suitable basic additives include ammonium sulfonate salts such as piperidinium p-toluenesulfonate and dicyclohexylammonium p-toluenesulfonate; alkyl amines such as tripropylamine and dodecylamine; aryl amines such as diphenylamine, triphenylamine, aminophenol, 2-(4-aminophenyl)-2-(4-hydroxyphenyl)propane, etc.

The resin component of resists of the invention is typically used in an amount sufficient to render an exposed coating layer of the resist developable such as with an aqueous alkaline solution. More particularly, a resin binder will suitably comprise 50 to about 90 weight percent of total solids of the resist. The photoactive component should be present in an amount sufficient to enable generation of a latent image in a coating layer of the resist. More specifically, the photoactive component will suitably be present in an amount of from about 1 to 40 weight percent of total solids of a resist. Typi-

10

cally, lesser amounts of the photoactive component will be suitable for chemically amplified resists.

The resist compositions of the invention also comprise a photoacid generator (i.e. "PAG") that is suitably employed in an amount sufficient to generate a latent image in a coating layer of the resist upon exposure to activating radiation. Preferred PAGs for imaging at 193 nm and 248 nm imaging include imidosulfonates such as compounds of the following formula:

wherein R is camphor, adamantane, alkyl (e.g. C<sub>1-12</sub> alkyl) and perfluoroalkyl such as perfluoro(C<sub>1-12</sub>alkyl), particularly perfluorooctanesulfonate, perfluorononanesulfonate and the like. A specifically preferred PAG is N-[(perfluorooctanesulfonyl)oxy]-5-norbornene-2,3-dicarboximide.

Sulfonate compounds are also suitable PAGs, particularly sulfonate salts. Two suitable agents for 193 nm and 248 nm imaging are the following PAGS 1 and 2:

Such sulfonate compounds can be prepared as disclosed in European Patent Application 96118111.2 (publication number 0783136), which details the synthesis of above PAG 1.

Also suitable are the above two iodonium compounds complexed with anions other than the above-depicted camphor-sulfonate groups. In particular, preferred anions include those of the formula RSO<sub>3</sub><sup>-</sup> where R is adamantane, alkyl (e.g. C<sub>1-12</sub>alkyl) and perfluoroalkyl such as perfluoro(C<sub>1-12</sub>alkyl), particularly perfluorooctanesulfonate, perfluorobutanesulfonate and the like.

Other known PAGS also may be employed in photoresists used in accordance with the invention. Particularly for 193 nm imaging, generally preferred are PAGS that do not contain aromatic groups, such as the above-mentioned imidosulfonates, in order to provide enhanced transparency.

Photoresists of the invention also may contain other optional materials. For example, other optional additives include anti-striation agents, plasticizers, speed enhancers, etc. Such optional additives typically will be present in minor concentrations in a photoresist composition except for fillers and dyes which may be present in relatively large concentrations, e.g., in amounts of from about 5 to 30 percent by weight of the total weight of a resist's dry components.

The photoresists used in accordance with the invention are generally prepared following known procedures. For example, a resist of the invention can be prepared as a coating composition by dissolving the components of the photoresist in a suitable solvent such as, e.g., a glycol ether such as 2-methoxyethyl ether (diglyme), ethylene glycol monomethyl ether, propylene glycol monomethyl ether; propylene glycol monomethyl ether acetate; lactates such as ethyl lactate or methyl lactate, with ethyl lactate being preferred; propionates, particularly methyl propionate, ethyl propionate and ethyl ethoxy propionate; a Cellosolve ester such as methyl Cellosolve acetate; an aromatic hydrocarbon such as toluene or xylene; or a ketone such as methylethyl ketone, cyclohexanone and 2-heptanone. Typically the solids content of the photoresist varies between 5 and 35 percent by weight of the total weight of the photoresist composition. Blends of such solvents also are suitable.

Liquid photoresist compositions may be applied to a substrate such as by spinning, dipping, roller coating or other conventional coating technique. When spin coating, the solids content of the coating solution can be adjusted to provide a desired film thickness based upon the specific spinning equipment utilized, the viscosity of the solution, the speed of the spinner and the amount of time allowed for spinning.

Photoresist compositions used in accordance with the invention are suitably applied to substrates conventionally used in processes involving coating with photoresists. For example, the composition may be applied over silicon wafers or silicon wafers coated with silicon dioxide for the production of microprocessors and other integrated circuit components. Aluminum-aluminum oxide, gallium arsenide, ceramic, quartz, copper, glass substrates and the like are also suitably employed. Photoresists also may be suitably applied over an antireflective layer, particularly an organic antireflective layer.

Following coating of the photoresist onto a surface, it may be dried by heating to remove the solvent until preferably the photoresist coating is tack free.

The photoresist layer (with overcoated barrier composition layer, if present) is then exposed in an immersion lithography system, i.e. where the space between the exposure tool (particularly the projection lens) and the photoresist coated substrate is occupied by an immersion fluid, such as water or water mixed with one or more additives such as cesium sulfate which can provide a fluid of enhanced refractive index. Preferably the immersion fluid (e.g., water) has been treated to avoid bubbles, e.g. water can be degassed to avoid nanobubbles.

References herein to "immersion exposing" or other similar term indicates that exposure is conducted with such a fluid layer (e.g. water or water with additives) interposed between an exposure tool and the coated photoresist composition layer.

The photoresist composition layer is then suitably patterned exposed to activating radiation with the exposure energy typically ranging from about 1 to 100 mJ/cm<sup>2</sup>, dependent upon the exposure tool and the components of the photoresist composition. References herein to exposing a photoresist composition to radiation that is activating for the

photoresist indicates that the radiation is capable of forming a latent image in the photoresist such as by causing a reaction of the photoactive component (e.g. producing photoacid from the photoacid generator compound).

As discussed above, photoresist compositions are preferably photoactivated by a short exposure wavelength, particularly a sub-400 nm, sub-300 and sub-200 nm exposure wavelength, with I-line (365 nm), 248 nm and 193 nm being particularly preferred exposure wavelengths as well as EUV and 157 nm.

Following exposure, the film layer of the composition is preferably baked at temperatures ranging from about 70° C. to about 160° C. Thereafter, the film is developed, preferably by treatment with an aqueous based developer such as quaternary ammonium hydroxide solutions such as a tetra-alkyl ammonium hydroxide solution; various amine solutions preferably a 0.26 N tetramethylammonium hydroxide, such as ethyl amine, n-propyl amine, diethyl amine, di-n-propyl amine, triethyl amine, or methyldiethyl amine; alcohol amines such as diethanol amine or triethanol amine; cyclic amines such as pyrrole, pyridine, etc. In general, development is in accordance with procedures recognized in the art.

Following development of the photoresist coating over the substrate, the developed substrate may be selectively processed on those areas bared of resist, for example by chemically etching or plating substrate areas bared of resist in accordance with procedures known in the art. For the manufacture of microelectronic substrates, e.g., the manufacture of silicon dioxide wafers, suitable etchants include a gas etchant, e.g. a halogen plasma etchant such as a chlorine or fluorine-based etchant such a Cl<sub>2</sub> or CF<sub>4</sub>/CHF<sub>3</sub> etchant applied as a plasma stream. After such processing, resist may be removed from the processed substrate using known stripping procedures.

All documents mentioned herein are incorporated herein by reference. The following non-limiting examples are illustrative of the invention.

#### EXAMPLE 1

##### Particle Additive Preparation

A preferred fluorinated particle additive is prepared as follows:

A reactor vessel is charged with a desired amount of propylene glycol monomethyl ether acetate (PGMEA) and heated to 80° C. with N<sub>2</sub> purge. The following monomers (PFPA, ECPMA, TMPTA), cross-linker and initiator (t-amyl peroxyvalate) are mixed in PGMEA at 80 to 90 weight % fluid composition in an ice bath. The initiator content is 4% relative to the total amount of monomers and cross-linker. The monomers were used in the following weight amounts: 70 weight % pentafluoracrylate (PFPA), 20 weight % ethyl cyclopentyl methacrylate (ECPMA), and 10 weight % TMPTA:

PFPA

That monomer/crosslinker/initiator/PGMEA mixture is then fed into the reactor vessel at a rate of approximately 1 ml/min. After the addition to the reactor vessel is complete, the temperature of mixture within the reactor vessel is held at 80° C. for 30 minutes. Then, an additional 2 weight % (relative to the total monomers and cross-linker) of initiator is fed into the reactor. After that addition, the temperature of the mixture within the reactor vessel is held at 80° C. for additional 2 hours. Thereafter, the temperature of the reactor vessel is permitted to cool to room temperature.

By that procedure, polymer particles were provided that had a number-average molecular weight (Mn) of 7088 and a weight-average molecular weight (Mw) of 19255.

#### EXAMPLE 2

##### Photoresist Preparation and Processing

A photoresist composition is prepared by admixing the following materials in the specified amounts:

1. Resin component: Terpolymer of (2-methyl-2-adamantyl methacrylate/beta-hydroxy-gamma-butyrolactone methacrylate/cyano-norbornyl methacrylate in an amount of 6.79 weight % based on total weight of the photoresist composition;

2. Photoacid generator compound: t-butyl phenyl tetramethylene sulfonium perfluorobutanesulfonate in an amount of 0.284 weight % based on total weight of the photoresist composition;

3. Base additive: N-Alkyl Caprolactam in an amount of 0.017 weight % based on total weight of the photoresist composition;

4. Surfactant: R08 (fluorine-containing surfactant, available from Dainippon Ink & Chemicals, Inc.) in an amount of 0.0071 weight % based on total weight of the photoresist composition

5. Substantially non-mixable additive:

(i) top resin material: a copolymer having 50 mole percent of the following two units and the depicted structure: 2-(4,4,4-bis-trifluoromethyl hydroxy) butyl methacrylate: t-butyl-methacrylate

(ii) intermediate material: 88/8/4 terpolymer of the following structure (88/8/4 mole percent of respective units from left to right in the following structure):

6. Solvent component: propylene glycol monomethyl ether acetate to provide about a 90 percent fluid composition.

The above photoresist composition containing is spin-coated onto silicon wafers, dried on vacuum hotplate to remove soft-plate and then exposed in an immersion lithography process with aqueous immersion fluid directly contacting the dried photoresist layers. In that immersion system, the photoresist layers is exposed to patterned 193 nm radiation at a dose of 24.1 mJ/cm<sup>2</sup> through a photomask.

The photoresist layer is then post-exposed baked (such as at about 120° C.) and developed with 0.26N alkaline aqueous developer solution.

To evaluate leaching of resist components after the post-exposure bake and before development, the immersion fluid can be evaluated for the photoacid in the resist and its photodegradation byproducts by LC/mass spectroscopy (60 second leaching time tested).

#### EXAMPLE 3

##### Additional Photoresist Preparation and Processing

A further photoresist composition is prepared by admixing the following materials in the specified amounts:

1. Resin component: Terpolymer of (2-methyl-2-adamantyl methacrylate/beta-hydroxy-gamma-butyrolactone methacrylate/cyano-norbornyl methacrylate in an amount of 6.79 weight % based on total weight of the photoresist composition;

## 15

2. Photoacid generator compound: t-butyl phenyl tetramethylene sulfonium perfluorobutanesulfonate in an amount of 0.284 weight % based on total weight of the photoresist composition;

3. Base additive: N-Alkyl Caprolactam in an amount of 0.017 weight % based on total weight of the photoresist composition;

4. Surfactant: R08 (fluorine-containing surfactant, available from Dainippon Ink & Chemicals, Inc.) in an amount of 0.0071 weight % based on total weight of the photoresist composition

5. Substantially non-mixable additive in an amount of 0.213 weight % based on total weight of the photoresist composition. The substantially non-mixable component contained the following two distinct top material and intermediate material:

(i) top resin material: a copolymer having 50 mole percent of each of the following two units and the depicted structure:

(ii) intermediate material: 25/25/20/30 tetrapolymer of the following structure (25/25/20/30 mole percent of respective units from left to right in the following structure):

6. Solvent component: propylene glycol monomethyl ether acetate to provide about a 90 percent fluid composition.

This photoresist composition is processed by the same procedures as described in Example 2 above.

## EXAMPLE 4

## Additional Photoresist Preparation and Processing

A further photoresist composition is prepared by admixing the following materials in the specified amounts:

1. Resin component: Terpolymer of (2-methyl-2-adamantyl methacrylate/beta-hydroxy-gamma-butyrolactone methacrylate/cyano-norbornyl methacrylate in an amount of 6.79 weight % based on total weight of the photoresist composition;

## 16

2. Photoacid generator compound: t-butyl phenyl tetramethylene sulfonium perfluorobutanesulfonate in an amount of 0.284 weight % based on total weight of the photoresist composition;

3. Base additive: N-Alkyl Caprolactam in an amount of 0.017 weight % based on total weight of the photoresist composition;

4. Surfactant: R08 (fluorine-containing surfactant, available from Dainippon Ink & Chemicals, Inc.) in an amount of 0.0071 weight % based on total weight of the photoresist composition

5. Substantially non-mixable additive in an amount of 0.213 weight % based on total weight of the photoresist composition. The substantially non-mixable component contained the following two distinct top material and intermediate material:

(i) top resin material: a 70/30 copolymer of the following structure (70/30 mole percent of respective units from left to right in the following structure):

(ii) intermediate material: 25/25/20/30 tetrapolymer of the following structure (25/25/20/30 mole percent of respective units from left to right in the following structure):

6. Solvent component: a 50:50 v/v ethyl lactate:propylene glycol monomethyl ether acetate blend to provide about a 90 percent fluid composition.

This photoresist composition is processed by the same procedures as described in Example 2 above.

The foregoing description of the invention is merely illustrative thereof, and it is understood that variations and modifications can be effected without departing from the scope or spirit of the invention as set forth in the following claims.

What is claimed is:

1. A method for processing a photoresist composition, comprising:

(a) applying on a substrate a photoresist composition comprising:

(i) a first resin that comprises photoacid-labile groups, and  
(ii) a photoactive component, and

**17**

- (iii) a second resin and a third resin where the second and third resins are substantially non-mixable with the first resin, and the first resin, second resin and third resin are each distinct from each other; and
- (b) immersion exposing the photoresist layer to radiation 5 activating for the photoresist composition.
2. The method of claim 1 wherein the second and third resins have differing surface energies.
3. The method of claim 1 wherein the second and third resins have differing relative hydrophobicities.
4. The method of claim 1 wherein the second and third resins comprise (i) a top material and (ii) and an intermediate material, and the top material and intermediate material have greater hydrophobicity relative to the first resin.
5. The method of claim 1 wherein the second and third resins comprise aqueous base-solubilizing groups.

**18**

6. The method of claim 1 wherein the second and third resins comprise photoacid-labile groups.
7. The method of claim 1 wherein the second and third resins comprise fluorine substitution.
8. The method of claim 6 wherein the second and third resins comprise fluorine substitution.
9. The method of claim 6 wherein the second and third resins comprise Si substitution.
10. The method of claim 1 wherein the second and third resins comprise (i) a top material and (ii) and an intermediate material, and the applied photoresist composition forms a layer with a substantial portion of the first resin closer to the substrate than a substantial portion of the second resin, and a substantial portion of the second resin is closer to the substrate than the third resin. 15
