(57) **ABSTRACT**

A second tank for accommodating a sample is disposed within a first tank. A heater for heating gas is provided inside the second tank. A heater controller controls the heater such that temperature of gas becomes a set temperature. A heat conducting member is disposed such that one end of the heat conducting member is positioned in the gas inside the first or second tank and the other end is positioned in the humidifying water contained in the humidifier. The heat conducting member is made of material having higher thermal conductivity than that of gas inside the first or second tank.

FIG. 2

1

**ENVIRONMENTAL TEST APPARATUS****CROSS-REFERENCE TO RELATED APPLICATIONS**

This application is a divisional application of the parent application, U.S. patent application Ser. No. 11/955,158, filed on Dec. 12, 2007.

**BACKGROUND OF THE INVENTION****1. Field of the Invention**

The present invention relates to an environmental test apparatus including a tank which accommodates a sample under a state where a constant temperature of inside gas is maintained.

**2. Description of Related Art**

JP-A-2005-121256 discloses an apparatus which executes tests including a test for checking operation condition of an electronic component under an environment where temperature and other conditions have been set at predetermined values. The apparatus shown in JP-A-2005-121256 includes a tank for accommodating a sample. The tank has a heating unit such as a heater, and the temperature of gas inside the tank is set at a predetermined value by appropriate control of the heating unit.

According to this type of apparatus, the gas temperature becomes excessively high when the gas in the tank is excessively heated. In this case, it may be difficult to maintain the gas temperature at the predetermined set value. For example, when an operation test is carried out for a sample which is an electronic component, heat is released from the electronic component. When a sample which generates heat is tested as in this case, positive cooling of the interior of the tank may be required.

When the tank is cooled from the outside of the tank, for example, gas existing around the inner surface of the tank is initially cooled. When the gas temperature reaches the dew point, moistures in the gas condense and adhere to the inner surface of the tank. In this case, the heat robbed from the gas by cooling is supplemented by condensation. Thus, the effect of cooling is difficult to reach the inside of the tank in some cases. Particularly when the tank has a multi-layer structure as in the structure disclosed in JP-A-2005-121256, only limited circulation of the gas occurs, and therefore the entire gas is further difficult to be cooled. When cooling the gas in the tank is difficult, excessive temperature increase of the gas inside the tank cannot be reduced. In this case, such a condition is possible where the temperature of the gas cannot be appropriately maintained at the set value.

**SUMMARY OF THE INVENTION**

It is an object of the invention to provide an environmental test apparatus capable of easily maintaining the temperature of gas inside a tank which has a multi-layer structure for accommodating a sample.

An environmental test apparatus provided according to an aspect of the invention includes: a first tank (as a first tank unit) which selectively switches between state where inside gas is sealed and state where the inside gas is opened to the outside; a second tank (as a second tank unit or passage unit) disposed within the first tank to accommodate a sample; a heater which heats gas inside the second tank; a heater controller which controls the heater such that the temperature of the gas inside the second tank becomes a set temperature; a humidifier which contains humidifying water and heats and

2

evaporates the humidifying water to humidify the gas inside the second tank; a humidifier controller which controls the humidifier to heat the humidifying water to a temperature lower than the set temperature such that the humidity of the gas inside the second tank becomes a set humidity; and a heat conducting member made of material having higher thermal conductivity than that of gas inside the first or second tank, the heat conducting member being disposed such that one end of the heat conducting member is positioned in the gas inside the first or second tank and the other end is positioned in the humidifying water contained in the humidifier.

According to this aspect of the invention, heat shifts from the gas inside the first or second tank toward the humidifying water through the heat conducting member made of material having thermal conductivity higher than that of the gas. Thus, the gas inside the first and second tanks can be efficiently cooled.

**BRIEF DESCRIPTION OF THE DRAWINGS**

Other and further objects, features and advantages of the invention will appear more fully from the following description taken in connection with the accompanying drawings in which:

FIG. 1 illustrates an inside structure including a part of a cross section of an environmental test apparatus according to an embodiment of the invention; and

FIG. 2 is a cross-sectional view taken along a line II-II in FIG. 1.

**DESCRIPTION OF THE PREFERRED EMBODIMENT**

FIG. 1 is a cross-sectional view of an environmental test apparatus 1 according to a preferred embodiment of the invention. The environmental test apparatus 1 has a test chamber 100 and a controller 150. The controller 150 controls the test environment such as the temperature of gas inside the test chamber 100. The controller 150 functions as either of a heater controller or humidifier controller of this invention.

The test chamber 100 has a multi-layer structure which combines an outer tank 103, a first inner tank 101, and a second inner tank 102 such that one tank fits inside another tank. These tanks are disposed in the order of the outer tank 103, the first inner tank 101, and the second inner tank 102 from the outside to the inside of the test chamber 100. The first and second inner tank 101 function as a first and second tank of this invention, respectively. The first inner tank 101 is accommodated in the outer tank 103, and the second inner tank 102 is accommodated in the first inner tank 101. A space is produced between the outer tank 103 and the first inner tank 101, and a cooling unit 142 is equipped in this space.

The first inner tank 101 is open to the left in FIG. 1. A cover 104 is provided on this opening. The cover 104 is supported by the first inner tank 101 via a not-shown opening and closing mechanism such that the close condition and the open condition can be selected. FIG. 1 shows the condition of the closed cover 104, in which state the interior of the first inner tank 101 is sealed. The opening and closing mechanism is constructed such that the sealed condition inside the first inner tank 101 can be maintained even when the pressure of the gas inside the first inner tank 101 is changed from the atmospheric pressure, and designed such that the user of the test chamber 100 can manually open and close the cover 104. According to the environmental test in this embodiment, it is assumed that the inside of the test chamber 100 is maintained at a pressure extremely higher than the atmospheric pressure.

The second inner tank **102** is open to the left in FIG. 1. A through hole **102a** penetrating through the second inner tank **102** in the left-right direction is formed at the right end of the second inner tank **102**. A sample table **102b** is provided within the second inner tank **102**.

A heater **141** is equipped in a space between the first inner tank **101** and the second inner tank **102** on the right side of the through hole **102a** in FIG. 1. A ventilation fan **131** is disposed on the right side of the heater **141**. A rotation shaft of the ventilation fan **131** is fixed to a driving shaft of a driving motor **132**. When the driving motor **132** is actuated, the fan **131** starts rotation and generates airflow toward the left. Thus, airflow in the direction indicated by white arrows in FIG. 1 is generated within the first inner tank **101** and the second inner tank **102**. This airflow introduces gas heated by the heater **141** through the through hole **102a** into the second inner tank **102**, thereby circulating gas inside the first inner tank **101** and the second inner tank **102**. Both the heater **141** and the driving motor **132** are connected with the controller **150**. The controller **150** switches ON/OFF condition of the heater **141**, and controls actuation of the driving motor **132**.

A humidifier **143** is equipped at a lower position of the first inner tank **101**. The humidifier **143** is fixed on the inner bottom surface of the first inner tank **101**, and stores humidifying water **W**. The humidifier **143** has a heater **144**, and a heating area of the heater **144** is soaked in the humidifying water **W** of the humidifier **143**. When the heater **144** is actuated, the humidifying water **W** is heated. The changed temperature of the humidifying water **W** changes the humidity inside the test chamber **100**. The heater **144** is connected with the controller **150**. The controller **150** switches ON/OFF condition of the heater **144**. The controller **150** thus adjusts the humidity of the gas inside the test chamber **100** to a predetermined value.

A dry-bulb temperature sensor **121** and a wet-bulb temperature sensor **122** are provided in the test chamber **100**. Both the dry-bulb temperature sensor **121** and the wet-bulb temperature sensor **122** are disposed inside the second inner tank **102**. The dry-bulb temperature sensor **121** and the wet-bulb temperature sensor **122** are connected with the controller **150**, and signals indicating temperatures detected at detecting portion of these sensors **121** and **122** are transmitted to the controller **150**. The controller **150** calculates the temperature and humidity of the gas inside the inner tank **102** based on the signals received from the dry-bulb temperature sensors **121** and the wet-bulb temperature sensor **122**. A water temperature sensor **123** is also provided for the humidifying water **W**. The temperature detected by the water temperature sensor **123** is chiefly used for the control of the heater **144** for humidity adjustment.

By using the structure discussed above, the controller **150** calculates the temperature and humidity of the gas inside the second inner tank **102**, and controls the heaters **141** and **144** and the driving motor **132** such that the temperature and humidity of the gas inside the second inner tank **102** become set temperature and set humidity established beforehand based on the calculated results. By this control, the gas inside the second inner tank **102** is maintained under predetermined environment corresponding to the set temperature and set humidity. Then, test for a sample **S** placed on the sample table **102b** is carried out under the predetermined environment. For example, the temperature and humidity inside the second inner tank **102** are set at 130° C. and 85%, respectively. Then, in case of an electronic circuit given as the sample **S**, the operation of the electronic circuit as the sample **S** is tested under the condition of the set temperature and set humidity.

When the temperature of the gas inside the second inner tank **102** rapidly increases by the heat generated from the sample **S** or for other reasons, for example, temperature control only by the heater **141** and the driving motor **132** may be insufficient for the level of this temperature increase in the second inner tank **102**. For avoiding this situation, the cooling unit **142** cools the first inner tank **101** under control of the controller **150** based on the signals from the dry-bulb temperature sensor **121** when predetermined conditions concerning the temperature of the gas inside the second inner tank **102** are satisfied.

When the cooling unit **142** starts cooling the first inner tank **101**, the inside gas is initially cooled from the vicinity of the inner surface of the first inner tank **101**. When the temperature of the gas in the vicinity of the inner surface of the first inner tank **101** reaches the dew point, condensation is produced on the inner surface of the first inner tank **101**. When the set temperature and set humidity are 130° C. and 85%, for example, the dew point of the gas satisfying these set conditions becomes 124.6° C. In this case, the difference between the set temperature of 130° C. and the dew point is small, and thus the temperature easily reaches the dew point by cooling. When the condensation is produced on the inner surface of the first inner tank **101**, most of the condensed dew flows downward along the inner surface of the first inner tank **101**. In this case, a part of the dew flows into the humidifying water of the humidifier **143**. Heat robbed from the gas inside the first inner tank **101** as a result of cooling by the cooling unit **142** is supplemented by heat generated through condensation thus produced. Thus, the gas inside the first inner tank **101** is not easily cooled, and the gas inside the second inner tank **102** provided further inside the first inner tank **101** is more difficult to be cooled.

For overcoming these drawbacks, the test chamber **100** according to this embodiment has protruding portions **111** protruding from the inner surface of the first inner tank **101**. FIG. 2 is a cross-sectional view of the test chamber **100** taken along a line II-II in FIG. 1. As illustrated in FIG. 2, the first inner tank **101** has the plural protruding portions **111**. Each upper end of the protruding portions **111** is fixed to the inner surface of the first inner tank **101**, and each lower end is disposed in the vicinity of the outer surface of the second inner tank **102**. Each of the protruding portions **111** has a flat plate shape. All the protruding portions **111** disposed on the left half of the first inner tank **101** extend from the inner surface of the first inner tank **101** toward the lower right in FIG. 2. All the protruding portions **111** disposed on the right half of the first inner tank **101** extend from the inner surface of the first inner tank **101** toward the lower left in FIG. 2.

Stainless steel wools **112** are fixed to the outer surface of the second inner tank **102**. Stainless steel wools **112** functions a blocking portion of this invention. The stainless steel wools **112** are disposed between the lower ends of the protruding portions **111** and the second inner tank **102**.

A heat pipe **113** is soaked in the humidifying water **W** stored in the humidifier **143**. The heat pipe **113** is a bar-shaped component made of stainless steel or other material. One end of the heat pipe **113** is disposed above the left end of the humidifier **143** as illustrated in FIG. 1. The other end of the heat pipe **113** contacts the inner bottom surface of the humidifier **143**. Thus, a part of the heat pipe **113** from one end to a predetermined length is exposed to above from the liquid level of the humidifying water **W**, and the remaining part is soaked below the liquid level.

Based on the structure discussed above, the second inner tank **102** is cooled in the following manner at the time of actuation of the cooling unit **142**. When the first inner tank

5

101 is cooled, condensation is produced on the inner surface of the first inner tank 101. Condensed dew D generated by this condensation flows along the inner surface of the first inner tank 101 and the protruding portions 111 toward the outer surface of the second inner tank 102 in the direction indicated by a white arrow in FIG. 2. The condensed dew having reached the outer surface of the second inner tank 102 is retained by the stainless steel wools 112. The gas inside the second inner tank 102 has a high temperature higher than the set temperature due to heat generated from the sample S or for other reasons. When the set temperature and set humidity are 130° C. and 85%, for example, the temperature of the gas inside the second inner tank 102 is higher than 130° C. In this condition, the dew point is 124.6° C. Since the temperature of the second inner tank 102 is higher than the dew point, the condensed dew retained by the stainless steel wools 112 evaporates. At this time, heat of vaporization is robbed from the outer surface of the second inner tank 102 by the evaporation of the condensed dew. As a result, the second inner tank 102 is cooled, and the gas inside the second inner tank 102 is cooled accordingly.

When the set temperature and set humidity are 130° C. and 85%, for example, the water temperature of the humidifying water is set at 124.6° C. Since the temperature of the humidifying water W is set at the set temperature or lower, a large difference is produced between the temperature of the gas and the temperature of the humidifying water W when the temperature of the gas inside the second inner tank 102 increases to a temperature higher than the set temperature. Thus, heat moves from the gas to the humidifying water W through the heat pipe 113 in the direction indicated by a black arrow in FIG. 1. As a result, the gas inside the second inner tank 102 is cooled.

As apparent from above, the condensed dew produced on the inner surface of the first inner tank 101 is guided through the protruding portions 111 toward the second inner tank 102, and is evaporated on the outer surface of the second inner tank 102. Thus, even when condensation is produced on the inner surface of the first inner tank 101, the second inner tank 102 is cooled by evaporation of the condensed dew on the outer surface of the second inner tank 102. As a result, the gas inside the second inner tank 102 is cooled.

In addition, the stainless wools 112 hold the condensed dew having reached the outer surface of the second inner tank 102. In other words, the stainless steel wools 112 have a function of blocking the downward flow of the condensed dew along the outer surface of the second inner tank 102. Thus, the condensed dew is easily retained on the outer surface of the second inner tank 102, and easily evaporated on the outer surface of the second inner tank 102 before the condensed dew flows downward to a lower position of the second inner tank 102.

Moreover, since the heat of the gas inside the first inner tank 101 and the second inner tank 102 moves to the humidifying water W through the heat pipe 113, the gas is easily cooled. It is preferable that the heat pipe 113 is made of material having highest possible thermal conductivity. However, any material may be used as long as it has higher thermal conductivity than that of the gas inside the first inner tank 101 and second inner tank 102.

#### Modified Example

While the preferred embodiment according to the invention has been described herein, the invention may be practiced otherwise without departing from the scope of the invention. For example, the following modifications may be made.

6

While the stainless steel wools 112 are used in this embodiment, any part or structure may be used as long as it can block the downward flow of the condensed dew on the outer surface of the second inner tank 102. For example, a plurality of grooves extending in parallel with the horizontal direction may be formed on the outer surface of the second inner tank 102 to enlarge the surface area of the outer surface. When a component for retaining the condensed dew such as stainless steel wools 112 is used, it is preferable that the component is made of material having the highest possible thermal conductivity.

While the bar-shaped heat pipe 113 is used in this embodiment, a component having a shape different from the bar shape may be used. For example, a component having a shape different from the shape of the heat pipe 113 and adjusted such that one end of the component reaches the inside of the second inner tank 102 with the other end soaked in the humidifying water W may be used as a member having the same function as that of the heat pipe 113.

According to this embodiment, the test chamber 100 has both the protruding portions 11 and the heat pipe 113. However, the test chamber 100 need not have both the protruding portions 111 and the heat pipe 113 but may contain either one of these. Since the protruding portions 111 and the heat pipe 113 are components functioning independently from each other, the advantage that the gas inside the second inner tank 102 is easily cooled can be offered when only either the protruding portions 111 or the heat pipe 113 is equipped.

While the cooling unit 142 is contained in the test chamber 100 in this embodiment, the environmental test apparatus 1 need not include the cooling unit 142. In this case, the test chamber 100 is cooled by using a certain cooling unit from the outside of the outer tank 103 or a component (not shown) covering the outside of the outer tank 103 is removed from the outer tank 103 so as to promote heat release from the test chamber 100 at the time of excessive increase in the temperature of the gas inside the second inner tank 102.

While this invention has been described in conjunction with the specific embodiments outlined above, it is evident that many alternatives, modifications and variations will be apparent to those skilled in the art. Accordingly, the preferred embodiments of the invention as set forth above is intended to be illustrative, not limiting. Various changes may be made without departing from the spirit and scope of the invention as defined in the following claims.

What is claimed is:

1. An environmental test apparatus, comprising:
  - a tank unit which selectively switches between state where inside gas is sealed and state where the inside gas is opened to the outside;
  - a passage unit which, within the tank unit, defines an internal passage space for accommodating therein a test piece, the internal passage space being extended from an opening formed at one end to another opening formed at another end;
  - a heater which heats gas inside the passage unit;
  - a heater controller which controls the heater such that the temperature of the gas inside the passage unit becomes a set temperature;
  - a humidifier which contains humidifying water and heats and evaporates the humidifying water to humidify the gas inside the passage unit;
  - a humidifier controller which controls the humidifier to heat the humidifying water to a temperature lower than the set temperature such that the humidity of the gas inside the passage unit becomes a set humidity; and

7

a heat conducting member made of material having higher thermal conductivity than that of gas inside the tank unit or the passage unit, the heat conducting member being disposed such that one end of the heat conducting member is positioned in the gas inside the tank unit and the other end is positioned in the humidifying water contained in the humidifier,

wherein the heat conducting member and a water surface of the humidifying water intersect at a position apart from the other end relative to a direction along the water surface of the humidifying water.

2. The environmental test apparatus according to claim 1, wherein a part of the heat conducting member in the humidifying water is extended in an oblique angle with respect to the water surface.

3. The environmental test apparatus according to claim 1, wherein the passage unit has two openings, and a fan which generates an airflow that flows from a space between a wall of the tank unit and the passage unit into the passage unit via one of the openings and flows out from the passage unit via the other one of the openings; and wherein a portion of the heat conducting member outside the humidifying water is disposed in the path of the airflow generated by the fan.

4. An environmental test apparatus, comprising:

a tank unit which selectively switches between state where inside gas is sealed and state where the inside gas is opened to the outside;

a passage unit which, within the tank unit, defines an internal passage space for accommodating therein a test

8

piece, the internal passage space being extended from an opening formed at one end to another opening formed at another end;

a heater which heats gas inside the passage unit;

a heater controller which controls the heater such that the temperature of the gas inside the passage unit becomes a set temperature;

a humidifier which contains humidifying water and heats and evaporates the humidifying water to humidify the gas inside the passage unit;

a humidifier controller which controls the humidifier to heat the humidifying water to a temperature lower than the set temperature such that the humidity of the gas inside the passage unit becomes a set humidity;

a heat conducting member made of material having higher thermal conductivity than that of gas inside the tank unit or the passage unit, the heat conducting member being disposed such that one end of the heat conducting member is positioned in the gas inside the tank unit and outside the humidifier and the other end is positioned in the humidifying water contained in the humidifier; and

a fan configured, at the passage, to generate an airflow that flows from a space between a wall of the tank unit and the passage unit into the passage unit via the opening at the one end and flows out from the passage unit via the opening at the other end,

wherein a portion of the heat conducting member outside the humidifier is disposed in the path of the airflow generated by the fan.
