

US008574282B2

(12) **United States Patent**
Andreas et al.

(10) **Patent No.:** **US 8,574,282 B2**
(45) **Date of Patent:** **Nov. 5, 2013**

(54) **APPARATUS AND METHODS FOR DELIVERY OF BRAIDED PROSTHESES**

(75) Inventors: **Bernard Andreas**, Redwood City, CA (US); **Ronald French**, Santa Clara, CA (US); **Mark E. Deem**, Mountain View, CA (US); **Hanson S. Gifford, III**, Woodside, CA (US); **Allan Will**, Atherton, CA (US)

(73) Assignee: **J.W. Medical Systems Ltd.**, Weihai Shangdong (CN)

(*) Notice: Subject to any disclaimer, the term of this patent is extended or adjusted under 35 U.S.C. 154(b) by 115 days.

(21) Appl. No.: **13/078,749**

(22) Filed: **Apr. 1, 2011**

(65) **Prior Publication Data**

US 2011/0178589 A1 Jul. 21, 2011

Related U.S. Application Data

(63) Continuation of application No. 12/040,598, filed on Feb. 29, 2008, now Pat. No. 7,938,852, which is a continuation of application No. 10/966,806, filed on Oct. 14, 2004, now Pat. No. 7,357,812, which is a continuation of application No. 10/306,620, filed on Nov. 27, 2002, now Pat. No. 7,147,656.

(60) Provisional application No. 60/336,607, filed on Dec. 3, 2001.

(57) **ABSTRACT**

Blood vessels and other body lumens are expanded using an evertible braided prosthesis. The braided prosthesis is delivered to the blood vessel in a radially collapsed configuration. A leading edge of the braided prosthesis is then everted so that it expands as it is advanced through the blood vessel. Optionally, the prosthesis can be provided with a biologically active substance in order to inhibit hyperplasia or have other desired biological effects.

FIG. 1

APPARATUS AND METHODS FOR DELIVERY OF BRAIDED PROSTHESES

CROSS-REFERENCES TO RELATED APPLICATIONS

The present application is a continuation of U.S. patent application Ser. No. 12/040,598, filed Feb. 29, 2008, which is a continuation of U.S. patent application Ser. No. 10/966,806, filed Oct. 14, 2004 (now U.S. Pat. No. 7,357,812 B2), which is a continuation of U.S. patent application Ser. No. 10/306,620, filed Nov. 27, 2002 (now U.S. Pat. No. 7,147,656), which claims priority to U.S. Provisional Patent Application Ser. No. 60/336,607, filed Dec. 3, 2001, the full disclosures of which are incorporated herein by reference.

BACKGROUND OF THE INVENTION

1. Field of the Invention.

The present invention relates generally to medical devices and methods. More particularly, the present invention relates to apparatus and methods for delivering braided and other everting prostheses within a body lumen, such as a blood vessel.

Coronary artery disease is the leading cause of death and morbidity in the United States and Western society. In particular, atherosclerosis in the coronary arteries can cause myocardial infarction, commonly referred to as a heart attack, which can be immediately fatal or even if survived, cause damage to the heart which can incapacitate the patient.

While coronary artery bypass surgery can be an effective treatment for stenosed arteries resulting from atherosclerosis or other causes, it is a highly invasive, costly procedure, which typically requires substantial hospital and recovery time. Percutaneous transluminal coronary angioplasty, commonly referred to as balloon angioplasty, is less invasive, less traumatic, and significantly less expensive than bypass surgery. Heretofore, however, balloon angioplasty has not been considered as effective a treatment as bypass surgery. The effectiveness of balloon angioplasty, however, has improved significantly with the introduction of stenting, which involves the placement of a scaffold structure within the artery which has been treated by balloon angioplasty. The stent inhibits abrupt reclosure of the artery and has some benefit in inhibiting subsequent restenosis resulting from hyperplasia.

Recently, experimental trials have demonstrated that coating stents with anti-proliferative drugs, such as paclitaxel, can significantly reduce the occurrence of hyperplasia in angioplasty treated coronary arteries which have been stented with the coated stents.

While the combination of balloon angioplasty with drug-coated stents holds great promise, significant challenges still remain. Of particular interest to the present invention, the treatment of extended or disseminated disease within an artery remains problematic. Most stents have a fixed length, typically in the range from 10 mm to 30 mm, and the placement of multiple stents to treat disease over a longer length requires the successive use of multiple balloon stent delivery catheters. Moreover, it can be difficult to stent an angioplasty-treated region of a blood vessel with the optimum stent length.

For these reasons, it would be desirable to provide improved stents, stent delivery systems, stenting methods, and the like, for the treatment of patients having coronary artery disease, as well as other occlusive diseases of the vasculature and other body lumens. In particular, it would be desirable to provide stents, delivery systems, and methods for the treatment of disseminated and variable length stenotic

regions within the vasculature. For example, it would be desirable to provide a practical method which permits a physician to deliver extended lengths of braided prostheses to blood vessels and other body lumens. At least some of these objectives will be met by the inventions described hereinafter.

2. Description of the Background Art.

U.S. Pat. No. 5,755,772 describes a tubular prosthesis and method for its implantation by positioning the prosthesis at a target site, and everting an end section to lock the stent after expansion has been completed; and U.S. Pat. No. 5,769,882 describes conformable tubular prostheses and their placement in blood vessels.

BRIEF SUMMARY OF THE INVENTION

The present invention provides methods and apparatus for the stenting of body lumens, typically blood vessels, and more typically coronary arteries. The methods and systems will also find significant use in the peripheral vasculature, the cerebral vasculature, and in other ducts, such as the biliary duct, the fallopian tubes, and the like. The terms "stent" and "stenting" are defined to include any of the wide variety of expandable scaffolds which are designed to be intraluminally introduced to a treatment site and expanded in situ to apply a radially outward force against the inner wall of the body lumen at that site. Stents commonly comprise an open lattice structure, typically formed from a malleable or elastic metal.

The stents of the present invention will comprise evertable structures which radially expand upon eversion to assume a non-collapsible diameter which remains in place within the body lumen to support the luminal wall. Typically, the evertable stent structures will comprise braided structures, but other structures, such as counterwound helices, will also be capable of eversion. In some instances, laser cut helical and other patterned metal tubes, particularly those formed from nickel titanium and other shape memory alloys, may be used. Thin wall tubes formed from polymeric materials, such as polyethylene terephthalate (PET), expanded polytetrafluoroethylene (e PTFE), may also find use, even without patterning.

The braided and other evertable stent structures of the present invention may be formed from metals, including both malleable metals and elastic metals, such as shape memory metals, as well as from polymeric materials. Usually, the braided structures will comprise individual ribbons of the desired material which are interwoven to form a braid so that the braid may be axially elongated to assume a narrow diameter configuration and thereafter be everted to assume a larger diameter configuration. By "evert" it is meant that a leading edge of the prosthesis is turned outwardly and backwardly relative to the narrow diameter portion thereof. In the preferred methods and apparatus of the present invention, as described in more detail below, such eversion will be achieved by initially holding the prosthesis in its narrow diameter configuration with the leading portion everted and fixed to an outer portion of a catheter. This leading portion is referred to as the "fixed end." The remainder of the prosthesis which remains in its narrow diameter configuration is held within a passage or lumen of a delivery catheter, and means are provided for pushing the "advanceable end" of the prosthesis which is in the lumen forwardly relative to the fixed end. In this way, the leading edge of the prosthesis moves forward continuously relative to the fixed end as it everts radially outwardly.

The use of such braided and other evertable prostheses provides a number of advantages. For example, the braided structure is highly flexible, particularly in its narrow diameter

configuration, allowing the introduction of relatively long stent segments without significantly limiting the ability of the delivery catheter to pass through torturous regions of the vasculature or other body lumens. Additionally, by everting the prosthesis so that its outer portion remains stationary 5 relative to the fixed end (and thus also relative to the delivery catheter), the stent will be able to pass through relatively small body lumens since it advances much like a tractor tread in moving forwardly through the lumen. In the case of vascular treatments, the stents of the present invention will usually be used following other primary interventions, such as angioplasty, atherectomy, aneurysm repair, or the like. It will be possible, however, in certain instances, to deliver the stent without prior intervention because of the ability to advance through tight lesions and to dilate the lesion as it passes therethrough. 15

Usually, the methods and apparatus of the present invention will be used to deliver a single stent having a predetermined length. In other instances, however, it will be possible to provide a means for severing the stent on the catheter itself. In such cases, the methods and apparatus of the present invention will be capable of delivering variable lengths of stent depending on the nature and extent of the disease being treated. That is, the apparatus will be used to deliver the stent under fluoroscopic or other observation, and after a desired length of stent has been deployed, the deployed length can be severed from the length which remains carried within the delivery catheter. 25

In one aspect of the present invention, a method for delivering a prosthesis to a body lumen comprises positioning a metallic tubular prosthesis at a target site within the body lumen. The prosthesis is then everted so that an inside surface is exposed radially outwardly and advanced over a length of the wall of the body lumen. Usually, positioning comprises introducing a delivery catheter having a passage which carries the tubular prosthesis at least partly in a radially collapsed configuration. Everting usually comprises pushing the tubular prosthesis from the catheter so that a leading portion of the prosthesis everts and radially expands as it exits the catheter or passage. This is usually accomplished by forwardly advancing a portion of the catheter to push the prosthesis from the catheter. In a preferred aspect of the present invention, an advanceable segment of the prosthesis is carried in the passage in the radially collapsed configuration. A fixed end of the prosthesis is held stationary relative to the catheter in a partially everted configuration. Everting then comprises pushing a proximal end (i.e., an end or portion of the prosthesis which is radially collapsed within the delivery catheter) to cause a middle portion of the prosthesis to progressively evert and advance distally relative to the fixed end. In the case of braided prostheses, the braided structure will shorten as the radius expands so that the "advanceable" proximal end prosthesis is pushed forward at a rate which is faster than the rate at which the everted prosthesis covers the wall of the body lumen. In preferred embodiments, the prosthesis releases an active substance which inhibits hyperplasia after the prosthesis has been placed in the body lumen. 50

In another aspect of the present invention, a method for delivering a stent to a blood vessel comprises positioning the stent at a target site within the blood vessel and everting the stent so that an inside surface is exposed radially outwardly and advanced over a length of a wall of the blood vessel. The stent, in turn, inhibits restenosis in the blood vessel. 60

In another aspect of the present invention, a method for delivering a prosthesis to a body lumen involves positioning a tubular prosthesis at a target site within the body lumen, the tubular prosthesis having a total length. The tubular prosthe-

sis is then everted so that an inside surface is exposed radially outwardly and a desired length of the tubular prosthesis is advanced over a length of a wall of the body lumen, the desired length being less than the total length. The method then includes severing a portion of the tubular prosthesis having the desired length to allow the portion to remain in the body lumen. 5

In another aspect of the present invention, a method for delivering a prosthesis to a body lumen involves positioning a delivery catheter carrying a tubular prosthesis at a target site within the body lumen, everting the tubular prosthesis so that an inside surface is exposed radially outwardly and advanced over a desired length of a wall of the body lumen, and deploying a portion of the tubular prosthesis having the desired length. A second length of the tubular prosthesis remains carried within the delivery catheter. 10

In another aspect of the present invention, an apparatus for delivering a prosthesis to a body lumen includes a catheter having a passage, a metallic tubular prosthesis carried in the passage at least partially in a radially collapsed configuration, and a slidable member in the catheter for advancing the prosthesis from the passage so that the prosthesis everts and radially expands as it is advanced. In some embodiments, the metallic tubular prosthesis is a shape memory metal. In some 25 embodiments, the metallic tubular prosthesis comprises a braided metal structure. Alternatively, the metallic tubular prosthesis may comprise an open lattice structure.

In yet another embodiment of the present invention, an apparatus for delivering a prosthesis to a blood vessel includes a catheter having a passage, a stent carried in the passage at least partially in a radially collapsed configuration, and a slidable member in the catheter for advancing the prosthesis from the passage so that said prosthesis everts and radially expands as it is advanced. The stent is configured to inhibit restenosis in the blood vessel. 30

In another aspect of the invention, an apparatus for delivering a prosthesis to a body lumen includes a catheter having a passage, a tubular prosthesis carried in the passage at least partially in a radially collapsed configuration, a slidable member in the catheter for advancing the prosthesis from the passage so that said prosthesis everts and radially expands as it is advanced, and a severing member in the catheter for severing a portion of the prosthesis to allow the portion to remain in the body lumen while a second portion of the prosthesis remains carried in the catheter. 40

These and other aspects and embodiments of the present invention will be described in further detail below, with reference to the attached drawing figures. 45

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a perspective view illustrating a stent delivery catheter constructed in accordance with the principles of the present invention. 55

FIGS. 2A-2D illustrate use of the catheter in FIG. 1 for deploying a braided stent within a stenosed region in a blood vessel.

DETAILED DESCRIPTION OF THE INVENTION

Referring now to FIG. 1, the stent delivery catheter 10 comprises a catheter body 12 having a proximal end 14 and a distal end 16. The catheter body 12 is formed from a conventional catheter material, such as a natural or synthetic polymer, such as silicone rubber, polyethylene, polyvinylchloride, polyurethane, polyester, polytetrafluoroethylene, nylon, and the like. The body may be formed as a composite having 65

5

one or more reinforcement layers incorporated within a polymeric shell in order to enhance strength, flexibility, and toughness. For intravascular use, the catheter body will typically have a length in the range from 40 cm to 150 cm, usually being between 40 cm and 120 cm for peripheral blood vessels and between 110 cm and 150 cm for coronary arteries. The outer diameter of the catheter body may vary depending on the intended use, typically being between 3 French and 15 French, usually from 5 French to 9 French (one French=0.33 mm).

Catheter **10** further comprises a handle **18** at its proximal end **14**. The handle has a guidewire port **20** at its distal end as well as a handle grip **24** which is actuatable to extend and release evertible prosthesis **30** from the distal end **16**. The catheter body **12** comprises an outer tube **32**, a middle tube **34** which is coaxially and slidably mounted within a lumen of the outer tube **32**, and an inner tube **36** which is slidably and coaxially mounted within a lumen of the middle tube **34**. Inner tube **36** has a central lumen for receiving a guidewire, as described in detail below.

Referring now to FIGS. 2A-2D, delivery of the prosthesis **30** within a stenosed region SR of a blood vessel BV is described. The distal end **16** of the catheter **10** is introduced over a guidewire GW to the stenosed region SR as shown in FIG. 2A.

At that point, the prosthesis **30** is advanced forwardly or distally into the stenosed region SR of the blood vessel BV, as shown in FIG. 2B. In particular, both the inner tube **36** and the middle tube **34** are advanced forwardly or distally relative to the outer tube **32**. This causes the leading edge **40** of the prosthesis **30** to advance into the stenosed region SR, engaging and partially dilating the lumen wall within this region.

As the inner tube **36** and middle tube **34** are further advanced, as shown in FIG. 2C, the leading edge **40** of the prosthesis advances out through the other end of the stenosed region SR. During this entire deployment, fixed end **42** of the prosthesis has remained on the distal end of the outer tube **32** of the delivery catheter **10**.

Once the prosthesis **30** is fully deployed, the outer tube **32** would be disengaged from the fixed end **42** of the prosthesis, e.g., by rotating or otherwise separating the catheter from the prosthesis, leaving the prosthesis **30** in place, as shown in FIG. 2D. As can be seen in FIG. 2D, the deployment of the prosthesis **30** has dilated the stenotic region. At this point, if the dilation is insufficient, or further anchoring of the prosthesis **30** is desired, a balloon or other expandable member may be expanded within the prosthesis **30** in a conventional manner. In one embodiment, for example, a balloon may be coupled with the outer tube **32** in such a way as to allow the balloon to be inflated to further anchor the prosthesis **30** in place.

It will be appreciated that the lengths, pitches, adjacent spacings, and the like, of the braided and other elements deployed according to the methods of the present invention

6

can be controlled at the discretion of the treating physician. Thus, the methods and apparatus of the present invention provide useful flexibility for the treating physician to treat extended and disseminated disease in the vasculature and other body lumens.

Although the foregoing invention has been described in some detail by way of illustration and example, for purposes of clarity of understanding, it will be obvious that certain changes and modifications may be practiced within the scope of the appended claims.

What is claimed is:

1. A method for delivering a prosthesis to a body lumen, said method comprising:

positioning a delivery catheter at a target site, the tubular catheter comprising:

an outer tube having a passage;

a tubular prosthesis carried in the passage of the outer tube at least partially in a radially collapsed configuration; and

an inner tube slidably disposed within the passage of the outer tube, the inner tube having a lumen for receiving a guidewire; and

advancing the inner tube distally relative to the outer tube to evert the tubular prosthesis so that an inside surface is exposed radially outwardly and advanced over a length of a wall of the body lumen.

2. The method of claim **1**, further comprising radially expanding the tubular prosthesis with an expandable member of the delivery catheter so that the tubular prosthesis applies a radially outward force against inner wall.

3. The method of claim **1**, further comprising severing the tubular prosthesis with a separation element so that a first portion of the tubular prosthesis is deployed at the target site while another portion of the tubular prosthesis remains carried in the passage.

4. The method of claim **1**, further comprising operating a handle at a proximal end of the delivery catheter to advance the inner tube to evert the tubular prosthesis.

5. The method of claim **1**, further comprising inflating a balloon so as to anchor the tubular prosthesis to the body lumen.

6. The method of claim **1**, wherein the delivery catheter further comprises a middle tube slidably disposed within the passage of the outer tube and slidably disposed over the inner tube, and wherein the method further comprises advancing the middle tube with the inner tube to evert the tubular prosthesis.

7. The method of claim **1**, further comprising releasing a therapeutic agent from the tubular prosthesis after deployment thereof.

8. The method of claim **7**, wherein the therapeutic agent inhibits restenosis.
