(57) **ABSTRACT**

Stack elements corresponding to system object are associated with a stack item and aggregated in the stack item. A context engine provides contextual control of the stack item and stack elements.

## 47 Claims, 31 Drawing Sheets

## 1

## OBJECT STACK

## BACKGROUND

A graphical user interface allows a large number of graphical objects or items to be displayed on a display screen at the same time. Leading personal computer operating systems, such as the Apple Mac OS®, provide user interfaces in which a number of graphical representations of system objects can be displayed according to the needs of the user. Example system objects include system functions, alerts, windows, peripherals, files, and applications. Taskbars, menus, virtual buttons, a mouse, a keyboard, and other user interface elements provide mechanisms for accessing and/or activating the system objects corresponding to the displayed representations.

The graphical objects and access to the corresponding system objects and related functions, however, should be presented in a manner that facilitates an intuitive user experience. The use of metaphors that represent concrete, familiar ideas facilitate such an intuitive user experience. For example, the metaphor of file folders can be used for storing documents; the metaphor of a file cabinet can be used for storing information on a hard disk; and the metaphor of the desktop can be used for an operating system interface.

As the capabilities of processing devices progress, however, so do the demands on the graphical user interface to convey information to the users in an intuitive manner.

## SUMMARY

Disclosed herein systems, apparatus and methods for graphical user interface object stacks. In one implementation, graphical user interface includes a plurality of stack elements, and each stack element corresponds to an application. The stack elements include file elements associated with application document files and an application element associated an application executable. A stack item is associated with the plurality of stack elements. The stack item includes an aggregation of the stack elements in which the application element is in preeminent disposition.

In another implementation, a plurality of stack elements are generated, and each stack element corresponds to a computer system object. The plurality of stack elements are associated with a stack item, and the stack elements are aggregated into the stack item. Context control of the stack item is provided.

In another implementation, a computer readable medium stores instructions that are executable by a processing device, and upon such execution cause the processing device to generate a graphical user interface on a display device. The graphical user interface includes a plurality of stack elements, each stack element corresponding to a system object, and a stack item associated with the plurality of stack elements. The stack item includes an aggregation of the stack elements. The instructions also include a context engine that upon execution by the processing device provides contextual control of the stack item.

## BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a block diagram of an example system that can be utilized to implement the systems and methods described herein.

FIG. 2 is a block diagram of an example user interface architecture.

## 2

FIG. 3 is an image of an example visualization object receptacle.

FIG. 4 is an image of an example stack item.

FIG. 5 is a block diagram of an example user interface engine architecture.

FIG. 6 is a block diagram of an example system layer structure that can be utilized to implement the systems and methods described herein.

FIG. 7 is a block diagram of an example multidimensional desktop environment.

FIG. 8 is another block diagram of the example multidimensional desktop environment.

FIG. 9 is another block diagram of the example multidimensional desktop environment.

FIG. 10 is another block diagram of the example multidimensional desktop environment.

FIG. 11 is a block diagram of another example multidimensional desktop environment.

FIG. 12 is a block diagram of another example multidimensional desktop environment.

FIG. 13 is a block diagram of another example multidimensional desktop environment.

FIG. 14 is a block diagram of another example multidimensional desktop environment.

FIG. 15 is a block diagram of another example multidimensional desktop environment.

FIGS. 16A-D are block diagrams of other example multidimensional desktop environments.

FIG. 17 is a block diagram of an example desktop transition.

FIGS. 18A-18D are block diagrams of example visualization object receptacle indicators.

FIGS. 19A and 19B are block diagrams of an example contextual menu for a visualization object receptacle.

FIG. 20 is a block diagram of an example visualization object receptacle including type-ahead indications.

FIGS. 21A and 21B are block diagrams of example selection indicators for a visualization model.

FIG. 22 is a block diagram of another example multidimensional desktop environment.

FIG. 23 is a block diagram of another example visualization object receptacle.

FIG. 24 is a block diagram of an example stack item.

FIG. 25 is a block diagram of another example stack item.

FIG. 26 is a block diagram of another example stack item.

FIG. 27 is a block diagram of another example stack item.

FIGS. 28A and 28B are block diagrams of example stack items that are color-coded.

FIG. 29 is a block diagram illustrating an example contextual control scheme applied to an example stack item.

FIG. 30 is a block diagram illustrating the application of an example visualization model to an example stack item.

FIGS. 31A and 31B are block diagrams illustrating the application of another example visualization model to an example stack item.

FIG. 32 is a block diagram illustrating the application of another example visualization model to an example stack item.

FIG. 33A is a block diagram of an example group association of an example stack item.

FIG. 33B is a block diagram of an example group association of system objects.

FIG. 34 is a flow diagram of an example process for transitioning a desktop.

FIG. 35 is a flow diagram of another example process for transitioning between desktop types.

## 3

FIG. 36 is a flow diagram of an example process for generating a multidimensional desktop environment.

FIG. 37 is a flow diagram of an example process for rendering a side surface in a multidimensional desktop environment.

FIG. 38 is a flow diagram of an example process for scrolling a side surface in a multidimensional desktop environment.

FIG. 39 is a flow diagram of an example process for generating a selection indicator.

FIG. 40 is a flow diagram of an example process for rendering desktop items.

FIG. 41 is a flow diagram of an example process for generating an example application environment in a multidimensional desktop environment.

FIG. 42 is a flow diagram of an example process for transitioning between application environments.

FIG. 43 is a flow diagram of an example process for generating a visualization object receptacle.

FIG. 44 is a flow diagram of an example process for color coding visualization objects.

FIG. 45 is a flow diagram of an example process for color coding visualization objects of related system objects.

FIG. 46 is a flow diagram of another example process for generating a visualization object receptacle.

FIG. 47 is a flow diagram of an example process for generating a stack item.

FIG. 48 is a flow diagram of an example process for displaying stack elements according to modal states.

FIG. 49 is a flow diagram of an example process for selecting interaction models and/or visualization models.

FIG. 50 is a flow diagram of another example process for generating a stack item.

FIG. 51 is a flow diagram of an example process for displaying a stack item according to an execution context.

FIG. 52 is a flow diagram of an example process for generating and displaying a stack item.

FIG. 53 is a flow diagram of an example process for automatically selecting and applying an interaction model to a stack item.

FIG. 54 is a flow diagram of another example process for automatically selecting and applying an interaction model to a stack item.

FIG. 55 is a flow diagram of another example process for automatically selecting and applying an interaction model to a stack item.

FIG. 56 is a flow diagram of another example process for automatically selecting and applying an interaction model to a stack item.

FIG. 57 is a flow diagram of an example process for generating a divet.

FIG. 58 is a flow diagram of an example process for generating a divet contextual menu.

## DETAILED DESCRIPTION

FIG. 1 is a block diagram of an example system 100 that can be utilized to implement the systems and methods described herein. The system 100 can, for example, be implemented in a computer device, such as any one of the personal computer devices available from Apple Inc., or other electronic devices. Other example implementations can also include video processing devices, multimedia processing devices, portable computing devices, portable communication devices, set top boxes, and other electronic devices.

The example system 100 includes a processing device 102, a first data store 104, a second data store 106, a graphics

## 4

device 108, input devices 110, output devices 112, and a network device 114. A bus system 116, such as a data bus and a motherboard, can be used to establish and control data communication between the components 102, 104, 106, 108, 110, 112 and 114. Other example system architectures, however, can also be used.

The processing device 102 can, for example, include one or more microprocessors. The first data store 104 can, for example, include a random access memory storage device, such as a dynamic random access memory, where the dynamic random access memory includes computer-readable medium. The second data store 106 can, for example, include one or more hard drives, a flash memory, and/or a read only memory, each of which includes computer-readable medium.

The graphics device 108 can, for example, include a video card, a graphics accelerator card, or a display adapter, and is configured to generate and output images to a display device. In one implementation, the graphics device 108 can be realized in a dedicated hardware card connected to the bus system 116. In another implementation, the graphics device 108 can be realized in a graphics controller integrated into a chipset of the bus system 116. Other implementations can also be used.

Example input devices 110 can include a keyboard, a mouse, a stylus, a video camera, a multi-touch surface, etc., and example output devices 112 can include a display device, an audio device, etc.

The network interface 114 can, for example, include a wired or wireless network device operable to communicate data to and from a network 118. The network 118 can include one or more local area networks (LANs) or a wide area network (WAN), such as the Internet.

In an implementation, the system 100 includes instructions defining an operating system stored in the first data store 104 and/or the second data store 106. Example operating systems can include the MAC OS® X series operating system, the WINDOWS® based operating system, or other operating systems. Upon execution of the operating system instructions, access to various system objects is enabled. Example system objects include data files, applications, functions, windows, etc. To facilitate an intuitive user experience, the system 100 includes a graphical user interface that provides the user access to the various system objects and conveys information about the system 100 to the user in an intuitive manner.

FIG. 2 is a block diagram of an example user interface architecture 200. The user interface architecture 200 includes a user interface (UI) engine 202 that provides the user access to the various system objects 204 and conveys information about the system 100 to the user.

Upon execution, the UI engine 202 can cause the graphics device 108 to generate a graphical user interface on an output device 112, such as a display device. In one implementation, the graphical user interface can include a multidimensional desktop 210 and a multidimensional application environment 212. In an implementation, the multidimensional desktop 210 and the multidimensional application environment 212 include x-, y- and z-axis aspects, e.g., a height, width and depth aspect. The x-, y- and z-axis aspects may define a three-dimensional environment, e.g., a “3D” or “2.5D” environment that includes a z-axis, e.g., depth, aspect.

In an implementation, the multidimensional desktop 210 can include use interface elements, such as visualization objects 220, a visualization object receptacle 222, and stack items 224. In some implementations, the visualization objects 220, the visualization object receptacle 222 and the stack items 224 can be presented in a pseudo-three dimensional

## 5

(i.e., “2.5D”) or a three-dimensional environment as graphical objects having a depth aspect.

A visualization object **220** can, for example, be a visual representation of a system object. In some implementations, the visualization objects **220** are icons. Other visualization objects can also be used, e.g., alert notification windows, menu command bars, windows, or other visual representations of system objects.

In an implementation, the multidimensional application environment **212** can include an application environment distributed along a depth aspect. For example, a content frame, e.g., an application window, can be presented on a first surface, and control elements, e.g., toolbar commands, can be presented on a second surface.

FIG. **3** is an image of an example visualization object receptacle **300**. In one implementation, the visualization object receptacle **300** can include x-, y- and z-axis aspects, e.g., a height, width and depth. In another implementation, the visualization object receptacle **300** can have only a y- and z-axis aspect, e.g., a width and depth. In another implementation, the visualization object receptacle **300** can have only an x- and y-axis aspect, e.g., a height and a width. An example implementation of a visualization object receptacle **300** is the “Dock” user interface in the MAC OS® X Leopard operating system. Other implementations can also be used.

In some implementations, or more visualization objects, e.g., icons **304**, **306**, **308** and **310** can be disposed within the visualization object receptacle **300**, e.g., an icon receptacle **300**. In one implementation, a lighting and shading effect is applied to emphasize the depth aspect of the visualization object receptacle **300**, as illustrated by the corresponding shadows **305**, **307**, **309** and **311** and reflections **312**, **314**, **316** and **318** beneath each of the icons **304**, **306**, **308** and **310**.

In some implementations, the visualization object receptacle **300** can include front surface **319** to generate a height aspect. In some implementations, a notch **320** can be included in the visualization object receptacle **300**. The notch **320** can, for example, be utilized to arrange visualization objects related to particular programs or functions, e.g., files and folders can be disposed on a first side of the notch **320** and applications can be disposed on a second side of the notch **320**; or a user may define arrangements according to the notch **320**, etc.

In some implementations, the visualization object receptacle **300** can include status indicators, e.g., **330** and **332**, disposed on the front surface **319**. The status indicators **330** and **332** can, for example, appear as illuminations to indicate a status of a system object or function associated with a corresponding visualization object. In some implementations, the status indicators can be color coded based on an identified status. For example, the status indicator **330** may be illuminate in a yellow color to indicate that the folder **304** is receiving a file download, and the status indicator **332** may be illuminate in a green color to indicate that a program associated with the visualization object **308** is running.

In some implementations, the visualization object receptacle **300** may only define a depth aspect, e.g., the visualization object receptacle **300** may not include a front surface **319**. In some implementations, the top surface of the visualization object receptacle **300** can be modeled as a liquid for addition and removal of visualization objects. For example, when a visualization object is added to the visualization object receptacle **300**, the adjacent visualization objects may move apart to define an open space, and the added visualization object may emerge from the surface into the open space. Surface perturbations, e.g., ripples, can be generated to

## 6

enhance the visual effect of the addition of the visualization object. Visualization objects can be removed by a substantially reversed visual effect.

In another implementation, when a visualization object is added to the visualization object receptacle **300**, the adjacent visualization objects may move apart to define an open space, and the added visualization object may fall onto the surface into the open space. Surface perturbations, e.g., ripples and splashes, can be generated to enhance the visual effect of the addition of the visualization object. Visualization objects can be removed by a substantially reversed visual effect. Additional features of visualization object receptacles and visualization objects disposed therein are described in more detail below.

FIG. **4** is an image of an example stack item **400**. In one implementation, the stack item **400** is a system object that includes a plurality of stack elements, e.g., stack elements **402**, **404**, **406** and **408**, such as icons corresponding to system objects, or other visualizations of system objects. The stack item **400** is associated with the stack elements **402**, **404**, **406** and **408** so that selection of the stack item can provide access to any of the stack elements **402**, **404**, **406** and **408**. In one implementation, a stack element can, for example, be realized by a corresponding visualization object of a system object. In another implementation, a stack element can, for example, be realized by a corresponding thumbnail icon of a system object. In another implementation, a stack element can, for example, be realized by a different corresponding icon of a system object. In another implementation, a stack element can, for example, be realized by a common stack element icon. Other stack element realizations with icons and/or other visualization objects can also be used.

In one implementation, a stack item identifier **410** can be displayed on the top stack element, e.g., stack element **402**. In one implementation, the stack item identifier **410** can, for example, comprise a title describing a stack type, e.g., “images” or “documents.” In another implementation, the stack item identifier **410** can, for example, comprise a visual indicator indicating an aspect of the stack, e.g., a dollar sign \$ can be displayed for a stack item including system objects related to a financial analysis tool; or a representation of a coin can be displayed as a surface beneath the stack item, etc. The stack item identifier **410** can, for example, be automatically generated, or can be generated by the user. Other stack item identifiers can also be used.

In one implementation, the stack elements **402**, **404**, **406** and **408** are aggregated in an overlapping arrangement as shown in FIG. **4**. Other stack arrangements can also be used. In one implementation, each stack element **402**, **404**, **406** and **408** displays a corresponding unique indicium **412**, **414**, **416** and **418**, e.g., a thumbnail preview of an image associated with the stack element or the first page of a document associated with the stack element. Other unique indicium or unique indicia can also be used. For example, stack elements corresponding to images can be of the same aspect of the image, e.g., a 4×5 aspect, and 9×12 aspect, etc. Likewise, stack items corresponding to documents can be of the same aspect of a paper selection, e.g., an 8.5×11 aspect, an A4 aspect, etc. Other unique indicium or indicia can also be used, e.g., a document size and/or a document date can be displayed in each stack element, etc.

In some implementations, the stack elements **402**, **404**, **406** and **408** can be normalized to or in a similar display aspect. For example, stack elements corresponding to images of different aspects, e.g., a 4×5 aspect, and 9×12 aspect, etc., can be of the same display aspect by the addition of borders surrounding a thumbnail of the thumbnail image. Such normal-

ization can facilitate a consistent presentation of system objects having inconsistent characteristics, e.g., different formatting sizes.

The stack item **400** can include visualization objects related to different types of system objects. For example, a stack item can include stack elements related to peripheral devices, e.g., hard drives, universal serial bus devices, etc.; or can include stack elements related to application windows; or can include stack elements related to system functions, e.g., menus, a shutdown function, a sleep function, a backup function, etc.; or can include stack elements related to recent system alerts; or other system objects.

In some implementations, a stack item **400** can include visualization objects related to different system views. For example, the stack element **402** can correspond to a work environment; the stack element **404** can correspond to a gaming environment; the stack element **406** can correspond to a music environment; and the stack element **408** can correspond to a movie environment. Selection of any of the corresponding elements **402-408** can cause the user interface to transition to the corresponding environment.

In some implementations, a stack item **400** can include visualization objects related to multiple monitors. For example, if a monitor in a dual monitor user environment is disabled, the corresponding visualization objects displayed on the disabled monitor can collapse into a monitor stack on the remaining monitor.

Additional features of the stack items and corresponding stack elements are described in more detail below.

FIG. **5** is a block diagram of an example user interface engine architecture **500**. The UI engine **202** can, for example, include an interaction and visualization model engine **502**, a physics engine **504**, and a context engine **506**. Other engines can also be included.

In one implementation, the interaction and visualization model engine **502** can identify an association characteristic of associated visualization objects, e.g., icons. The associated graphical elements can be collectively displayed, e.g., in an object stack, or can be distributed in a desktop/folder hierarchy in which only one icon is displayed. Based on the identified characteristic, the interaction and visualization model engine **502** can automatically select an interaction model and/or visualization mode that defines how the user may interact with and view the associated graphical elements. For example, if an identified association characteristic is the quantity of associated icons, an interaction model and/or visualization model for browsing the documents related to the icons can be selected based on the quantity. For example, if the quantity of associated icons is less than a first threshold, e.g., four, a mouse-over of any one of the four associated icons can present the associated icons in juxtaposition. Likewise, if the quantity of associated icons is greater than the first threshold and less than a second threshold, e.g., 16, a mouse-over of any one of the associated icons can present the associated icons in an overlapping display in which the icons cycle from back to front. Additionally, if the quantity of associated icons is greater than the second threshold, then a mouse-over of any one of the associated icons can present a scrollable list of associated documents.

Other interaction models and visualization model selection schemes can also be implemented. For example, the interaction and visualization model engine **502** can cause related visualization objects to move across a user interface when a particular visualization object type is selected, e.g., selection of a word processing program icon may cause word processing document icons to move toward the word processing program icons. In another implementation, selection of a

visualization object can cause unrelated visualization objects to be de-emphasized (e.g., reduce in size), and/or related visualization objects to be emphasized (e.g., increase in size). In another implementation, selection of a visualization object can cause related visualization objects to become illuminated.

In one implementation, the physics engine **504** can apply a physics aspect, such as Newtonian physics models based on mass, velocity, etc., to the visual representations of system objects, such as icons. In an implementation, the icons can be modeled as rigid bodies or non-rigid bodies. For example, placing an icon on a surface next to adjacent icons can cause the adjacent icons to shift positions in response to a simulated disturbance from the icon placement. In one implementation, icon magnetism can be selectively enabled or disabled by the user. In one implementation, icons return to their initial positions upon a disabling of the magnetism aspect. In another implementation, a magnet icon can have a magnetism aspect selected by the user, e.g., a magnetism with respect to a word processing application, or a magnetism with respect to two or more applications, or a magnetism with respect to the last time a document was accessed, e.g., within the last two days, etc.

Other physics models can also be applied. For example, an application icon can include a magnetism aspect, and placing the magnetic application icon on the desktop can cause icons related to the application icon, e.g., icons representing application document files, to be attracted to the magnetic icon and move towards the magnetic icon. Likewise, icons for unrelated system objects, e.g., other application icons and other document icons, can be modeled as having an opposite magnetic polarity from the selected magnetic icon, and thus will be repulsed and shift away from the selected magnetic icon.

The context engine **506** can, for example, provide contextual control of a stack item based on a context. For example, stack items, such as the stack item **400**, can be defined according to a protection context. Accordingly, system objects corresponding to stack elements within the stack item cannot be deleted until dissociated from the stack item. In some implementations, a stack item **400** can have a locked context, and access to the stack item **400** can be password protected. Other contextual control can also be provided, such as contextual control based on a temporal context, e.g., a new object stack of recently added system objects; a download context, such as a download stack for recently downloaded files; or an execution context, or other context types.

FIG. **6** is block diagram of example system layers **600** that can be utilized to implement the systems and methods described herein. Other system layer implementations, however, can also be used.

In an implementation, a user interface engine, such as the UI engine **202**, or another UI engine capable of generating a three-dimensional user interface environment, operates at an application level **602** and implements graphical functions and features available through an application program interface (API) layer **604**. Example graphical functions and features include graphical processing, supported by a graphics API, image processing, support by an imaging API, and video processing, supported by a video API.

The API layer **604**, in turn, interfaces with a graphics library layer **606**. The graphics library layer **604** can, for example, be implemented as a software interface to graphics hardware, such as an implementation of the OpenGL specification. A driver/hardware layer **608** includes drivers and associated graphics hardware, such as a graphics card and associated drivers.

FIG. 7 is a block diagram 700 of an example multidimensional desktop environment. In the example implementation, the multidimensional desktop environment 700 includes a back surface 702 axially disposed, e.g., along the z-axis, from a viewing surface 704. In one implementation, the back surface 702 can, for example, be a two-dimensional desktop environment, including one or more menus 701 and 703. In one implementation, the viewing surface 704 can be defined by the entire image on a display device, e.g., a “front pane.” One or more side surfaces, such as side surfaces 706, 708, 710 and 712, are extended from the back surface 702 to the viewing surface 704. A visualization object receptacle, e.g., an icon 714 is generated on one or more of the side surfaces, such as side surface 706. Although only one visualization object receptacle is shown, addition icon receptacles can also be displayed, e.g., along the side surface 708.

In one implementation, a reflection region 716 can be generated on the side surface 706, e.g., the “floor.” In an implementation, a reflection of the back surface 702 and of graphical items placed on the reflection region 716 can be generated, e.g., shapes 760 and 762 generate reflections 761 and 763 in the reflection region 716.

In an implementation, the visualization object receptacle 714 is positioned at a forward terminus 718 of the reflection region 716. In one implementation, the forward terminus 718 can be offset by an axial distance  $d$  from the viewing surface 704. In another implementation, the forward terminus 718 can terminate at the plane defined by the viewing surface 704.

In an implementation, the side surfaces 706, 708, 710 and 712 can intersect at intersections 707, 709, 711 and 713, respectively. Although four side surfaces are shown in FIG. 7, fewer or greater numbers of side surfaces can be defined; for example, in an implementation, only side surfaces 706, 708 and 712 are defined, and there is an absence of a “top” side surface 710.

In an implementation, the intersections 707, 709, 711 and 713 of the side surfaces 706, 708, 710 and 712 can occur at different locations. For example, the multidimensional desktop environment can include intersections 707a, 709a, 711a and 713a that are horizontally disposed; or intersections 707b, 709b, 711b and 713b that are vertically disposed, or combinations of vertical, angled, and horizontal intersections.

In an implementation, the side surfaces 706, 708, 710 and 712 are colored to emphasize the back surface 702 and reflection region 716. For example, the side surfaces 706, 708, 710 and 712 can be black in color, or respective patterns or colors can be rendered on each side surface. Other differentiation schemes including color schemes and image schemes can also be applied.

The visualization object receptacle 714 can include a plurality of visualization objects, e.g., icons 720, 722, 724, 726, 728, 730, 732, 734, 736, 738, 740 and 742. The icons 720, 722, 724, 726, 728, 730, 732, 734, 736, 738, 740 and 742 can, for example, correspond to one or more system objects, such as applications, documents, and functions. The visualization object receptacle 714 and icons 720, 722, 724, 726, 728, 730, 732, 734, 736, 738, 740 and 742 can include features as described with respect to the visualization object receptacle 300 of FIG. 3, and as described in more detail below.

In an implementation, stack items 750, 752, 754, 756 and 758 are interposed between the visualization object receptacle 714 and the back surface 702. The stack items 750, 752, 754, 756 and 758 can include features as described with respect to FIG. 4 above, and as described in more detail below. In the implementation of FIG. 7, the stack items 750, 752,

754, 756 and 758 define type associations, e.g., images, movies, documents, presentations, and downloads, respectively. Other associations can also be used. The stack items 750, 752, 754, 756 and 758 can generate reflections 751, 753, 755, 757, and 759 in the reflection region 716.

Selection of a particular stack element in a stack item can, for example, launch an associated application if the stack element represents an application document; or perform a system function if the stack element represents a system function; or can instantiate some other system process.

In an implementation, a stack item can be placed on the visualization object receptacle 714. In another implementation, behavior of a stack item when in the visualization object receptacle 714 is similar to the behavior of the stack item when placed on the reflection region 716.

In an implementation, representations of system objects, e.g., icons, stack items, etc., can be disposed on the side surfaces 708, 710 and 712. For example, a window displayed on the back surface 702 can be selected and dragged to one of the side surfaces 708, 710, or 712. Likewise, a stack item, such as stack item 750, can be dragged and disposed on one of the side surfaces 708, 710, or 712.

In one implementation, a stack item is created when a representation of a system object, e.g., an icon, is placed on the surface of the reflection region 716. For example, an icon related to a document can be displayed on the surface 712; upon a selection, dragging and placement of the icon on the reflection region 716, a stack item is created with at least the icon as a stack element. In an implementation, a stack item can also be created by a keyboard input; for example, a user can create a stack item for open windows by a Ctrl-W input, or create a stack item for peripherals by a Ctrl-P input, etc. Other processes to create stack items can also be used.

In one implementation, existing stack items are displaced to provide space for a newly created stack item. In one implementation, the reflection region 716 can be defined by a surface aspect, such as an equable texture, and the stack items 750, 752, 754, 756 and 758 are displaced according to a physics model, e.g., a rigid-body Newtonian physics model. In another implementation, the reflection region 716 can be defined by a grid aspect, and the stack items 750, 752, 754, 756 and 758 are displaced according to a grid snap.

Other textures and surface behaviors can also be used. In one implementation, a motion model is dependent on a selected surface aspect. For example, an equable texture, such as an image of a hardwood floor or a polished metallic surface, can be associated with a rigid-body Newtonian physics model; conversely, a visible grid aspect, or a raised texture, such as an image of a carpet, pebbles, etc., can be associated with a grid snap. In another implementation, the motion mode and textures can be selected independently.

In one implementation, a maximum number of stack items can be displayed in the reflection region 716. Upon the insertion or creation of a new stack item, one or more existing stack items are removed from the reflection region 716. In one implementation, a consolidated stack item can be created. The consolidated stack item can, for example, be a collection of stack items with each stack item being represented by a corresponding stack element. Selection of a corresponding stack element in a consolidated stack item will cause the corresponding stack item to be positioned on the reflection region, and will likewise cause another stack item to be positioned in the consolidated stack item.

In another implementation, one or more existing stack items can be removed from the reflection region 716 by transitioning to an edge of the reflection region 716 and fading from view, e.g., the stack item 750 may shift towards the

## 11

intersection **707** and fade by an atomizing effect, by a falling effect, or by some other effect. In another implementation, one or more existing stack items are removed from the reflection region **716** by transitioning to an edge of the reflection region **716** and moving onto one of the side surfaces, e.g., the stack item **750** may shift towards the intersection **707** and move up the side surface **708**.

FIG. **8** is another block diagram **800** of the example multidimensional desktop environment. In the block diagram of FIG. **8**, the visualization object receptacle **714** has been adjustably disposed along a depth axis, e.g., a z-axis, such that the visualization object receptacle **714** is disposed on the back surface **702**. In one implementation, the visualization object receptacle **714** can, for example, be preeminently displayed. The visualization object receptacle **714** can, for example, be preeminently displayed by rendering the visualization object receptacle **714** in front of other graphical objects. For example, the icon **742** in the visualization object receptacle **716** is displayed in front of the stack item **750**. Other methods can be used to preeminently display the visualization object receptacle **714**, such as rendering graphical objects displayed in front of the visualization object receptacle as translucent objects.

FIG. **9** is another block diagram **900** of the example multidimensional desktop environment. The system implementing the multidimensional desktop environment graphical user interface, such as the system **100** of FIG. **1**, has received a selection command for the stack item **750**. A selection command for a stack item can be generated by, for example, a mouse-over, a mouse click, a keyboard input, or by some other input.

In the implementation shown in FIG. **9**, a visualization model that causes the stack elements **772**, **774**, **776** and **778** to be arranged in an overlapping fan is applied to the stack item **750**. Thus, in response to a user input, e.g., a selection or a mouse over, the first stack item **750** enters a second modal state from a first modal state and the forward most stack element **772** fans upward, followed by the stack items **774** and **776**. While the stack item **750** is selected, a user can, for example, select and open a document related to one of the stack elements **772**, **774**, **776** and **778** by positioning a cursor on one of the stack elements **772**, **774**, **776** and **778** and selecting the element (e.g., clicking on the element with a mouse cursor). Deselection of the stack item **750**, e.g., ceasing the mouse over, causes the stack elements **772**, **774**, **776** and **778** to collapse back into the stack item **750**, and the stack item returns to the first modal state. Other selection processes can also be used.

In one implementation, the stack elements **772**, **774**, **776** and **778** fan according to a fixed fanning path **780**. In another implementation, the stack elements **772**, **774**, **776** and **778** can fan according to a path defined by a mouse input received from a user. In another implementation, a fanning can define a path toward a central region, and thus the stack elements of each stack may fan according to respective fanning paths **780**, **782**, **784**, **786**, and **788**.

In one implementation, one of several interaction and/or visualization models can be automatically selected for application to a stack item, such as the stack item **750**. The selection can, for example, be based on a characteristic of the stack item **750**, e.g., the number of stack elements **772**, **774**, **776** and **778**, the type of the stack elements **772**, **774**, **776** and **778**, or some other characteristic. For example, if an identified association characteristic is the quantity of associated icons, a visualization and/or interaction model for browsing and interacting with the documents related to the icons can be selected based on the quantity. If the quantity of associated icons is

## 12

greater than a first threshold, e.g., three, a mouse-over of any one of the stack elements **772**, **774**, **776** and **778** can present the stack elements **772**, **774**, **776** and **778** in the fanning arrangement as shown in FIG. **9**.

Other interaction and/or visualization model selection criterion or criteria can also be used. For example, stack elements related to documents in the stack item **754** can be displayed in an overlapping leafing mode in which the document titles appear, as the user is more likely to discern the relevance of a document from the title than a thumbnail image of a first page of a document.

FIG. **10** is another block diagram **1000** of the example multidimensional desktop environment. The system implementing the multidimensional desktop environment graphical user interface, such as the system **100** of FIG. **1**, has received a selection command for the stack item **750**, and a visualization model that causes the stack elements **772**, **774**, **776** and **778** to be arranged as single instances, e.g., single icons, in a matrix display is automatically selected and applied to the stack item **750**. In the implementation of FIG. **10**, the selection criterion can, for example, be based on a quantity. For example, if the quantity of associated icons is less than a first threshold, e.g., five, a selection of the stack item **750** can present the stack elements **772**, **774**, **776** and **778** in substantial juxtaposition as shown in FIG. **10**.

In one implementation, a selection indicator can be generated to indicate a selected stack item. For example, an under-lighting effect **1002** can be generated to indicate selection of the stack item **750**. Other selection indicators can also be used, such as backlighting effects, enlargement effects, outlining effects, or other effects.

Additional stack items **1004** and **1006**, corresponding to the categories of online buddies and music, are also displayed in the block diagram **1000**. In one implementation, stack items, such as stack items **1004** and **1006**, can be contextually controlled. For example, in one implementation, the stack item **1004** can automatically appear when the system implementing the graphical user interface of FIG. **10**, such as the system **100** of FIG. **1**, receives a notification that an event associated with another user that is designated as an "online buddy" has occurred, e.g., the "online buddy" has logged onto a network.

In another implementation, a stack item, such as the stack item **1006**, can automatically appear when an application corresponding to the stack item is selected or executed. For example, selecting the icon **732**, which illustratively corresponds to a music application, will instantiate the stack item **1006** in accordance with a selection and/or execution context.

Other contextual controls can also be used, such as modal states, temporal contexts, etc.

FIG. **11** is a block diagram of another example multidimensional desktop environment. The multidimensional desktop environment of FIG. **11** includes a back surface **1102** axially disposed, e.g., along the z-axis, from a viewing surface **1104**. In one implementation, the back surface **1102** can, for example, be a two-dimensional desktop environment, including one or more menus **1101** and **1103**. In one implementation, the viewing surface can be defined by the entire image on a display device, e.g., a "front pane." One or more side surfaces, such as side surfaces **1106**, **1108**, **1110** and **1112**, are extended from the back surface to the viewing surface. A visualization object receptacle **1114** is generated on one or more of the side surfaces, such as side surface **1106**.

In one implementation, a reflection region **1116** can be generated on the side surface **1106**, e.g., the "floor." The

## 13

reflection region **1116** can, for example, generate a reflection of the back surface **1102** and desktop items placed on the reflection region **1116**.

In an implementation, the side surfaces **1106**, **1108**, **1110** and **1112** are colored to emphasize the back surface **1102** and the reflection region **1116**. For example, the side surfaces **1106**, **1108**, **1110** and **1112** can be black in color, or respective patterns, colors, or images can be rendered on each side surface. Other differentiation schemes including color schemes and image schemes can also be applied.

The visualization object receptacle **1114** can include a plurality of visualization objects, e.g., icons **1120**, **1122**, **1124**, **1126**, **1128** and **1130**. The icons **1120**, **1122**, **1124**, **1126**, **1128** and **1130** can, for example, include visualization objects corresponding to one or more system objects, such as applications, documents, and functions. For example, icons **1120**, **1122** and **1124** can correspond to applications; icons **1126** and **1128** can correspond to stack items; and icon **1130** can correspond to a deletion function. Other system objects can also be represented, such as file items, peripheral items, etc.

In an implementation, stack items **1140**, **1142**, **1144** and **1146** are interposed between the visualization object receptacle **1114** and the back surface **1102**. A selection indicator can, for example, be generated to indicate a selected stack item. For example, an enlargement effect can be used to indicate a selection of the stack item **1146**. Other selection indicators can also be used.

In an implementation, the reflection region **1116** can be defined by a grid aspect **1150**, and the stack items **1140**, **1142**, **1144** and **1146** are displaced according to a grid snap. In one implementation, the grid aspect **1150** can be visible, e.g., a grid outline, or an association with a texture image. In another implementation, the grid aspect can be invisible.

In another implementation, stack items can be scrolled from side-to-side and/or from front-to-back (or back-to-front) on the surface **1106**. For example, upon a selection of the surface **1106**, e.g., by clicking on the surface **1106**, the surface **1106** can be scrolled in the directions indicated by the arrows **1152** and **1154**. The floor surface can include a scroll ingress and a scroll egress in which a scroll direction transitions from the scroll ingress to the scroll egress. For example, intersections **1156** and **1158** may define a scroll ingress and a scroll egress for a left-to-right scroll direction, or the left edge **1157** and the right edge **1159** of the reflection region **1116** may define a scroll ingress and a scroll egress for a left-to-right scroll direction. In one implementation, stack items are emplaced on the floor surface **1106** at the scroll ingress **1156** (or **1157**), and displaced from the floor surface **1106** at the scroll egress **1158** (or **1159**). In one implementation, one or more existing stack items are displaced from the surface **1106** by fading from view, e.g., fading by an atomizing effect, by a falling effect, or by some other effect.

In another implementation, one or more existing stack items are displaced from the surface **1106** moving onto one of the side surfaces, e.g., surface **1112**. In another implementation, one or more existing stack items are removed from the surface **1106** by moving into a stack element that includes displaced stacks, e.g., “anchor” stacks near the intersections **1156** and **1158**.

In one implementation, windows, such as windows **1160**, **1162** and **1164**, can be displayed on the back surface **1102**. The windows **1160**, **1162** and **1164** can, for example, be selected and placed on one or more of the surfaces **1106**, **1108**, **1110** and **1112**. In one implementation, placing a window on one of the surfaces, such as the reflection region **1116** of the surface **1106**, generates a stack item having the selected

## 14

window as a stack element. Selecting the stack item can, for example, cause the window to reappear in the original position on the back surface **11102**.

In one implementation, placing a window on one of the surfaces, such as the surface **1108**, generates a representation of the window, e.g., a window thumbnail **1170** on surface **1108**. The corresponding window can, for example, be restored by dragging the window thumbnail onto the back surface **1102**, or by selecting and double-clicking on the window thumbnail **1170**, or by some other command invocation.

In one implementation, a lighting aspect can generate a shadow and/or reflection for representations of system objects placed on a side surface. For example, a lighting aspect can generate a reflection or shadow **1172** of the window thumbnail **1170**. In one implementation, a shadow and/or reflection cast on the reflection region **1116** from the back surface **1102** can be limited to a selected representation of a system object. For example, if the window **1160** is currently selected, the shadow or reflection on the reflection region **1116** can be limited to the window **1160**, and the remaining windows **1162** and **1164** will not generate a reflection.

In another implementation, the lighting aspect can generate an illumination effect from the window thumbnail **1170** onto one or more surfaces. For example, the illumination effect can comprise a simulated sunbeam emanating from the window **1170**. In one implementation, the illumination effect can change according to local environmental states, e.g., the sunbeam can track across the surfaces according to a local time; the intensity of the sunbeam can be modulated according to the local time and local weather conditions that are received over the network **118**, e.g., high intensity for sunny days, low intensity for overcast days and during the early evening, and/or being eliminated after a local sunset time and generated after a local sunrise time.

In another implementation, the lighting aspect described above can be associated with a weather widget that can be displayed on one or more of the surfaces. Selection of the weather widget can, for example, provide a detailed weather summary of a selected region.

In another implementation, a stack item, such as the stack item **1128**, can be operatively associated with window instances, such as windows **1160**, **1162** and **1164**. In one implementation, the windows **1160**, **1162** and **1164** are minimized as stack elements **1161**, **1163** and **1165**, respectively, in the stack item **1128** in response to a first command, and the windows **1160**, **1162** and **1164** are displayed on the back surface **1102** from the minimized state in response to a second command.

In an implementation, the first and second commands are toggle commands. For example, selection of the entire stack item **1128**, e.g., by receiving a click command substantially concurrently with a mouse-over on the stack item **1128**, can cause all windows associated with the stack element, e.g., windows **1160**, **1162** and **1164**, to appear on the back surface **1102**. Upon cessation of the click command, the windows **1160**, **1162** and **1164** revert to the minimized state.

In another example implementation, selection of a stack element, such as selection of the stack element **1163** by receiving a click command after a cursor has hovered over the stack element **1163** in excess of a time period, can cause the stack element **1163** to be removed from the stack item **1128**. In response, the window **1162** can reappear on the back surface **1102**.

In an implementation, the lighting aspect can be configured to generate a shadow effect for each representation of a system object. For example, a selected window can cast shadows

## 15

on subsequent windows to emphasize a depth aspect and an overall user interface relationship; a stack item can cast a shadow on adjacent representations of systems objects; selecting an dragging an icon can cause a shadow of the icon to be generated on the side and back surfaces as the icon is moved, etc.

FIG. 12 is a block diagram of another example multidimensional desktop environment. In the implementation of FIG. 12, the reflection region 1116 is defined by surface aspect having an equable texture on which stack items are displaced in response to a new stack item. For example, the stack items 1202, 1204, 1206 and 1208 can move in response to the addition of a new stack item 1210. As the new stack item 1210 drops onto the surface 1106, the stack items 1206 and 1208 move in response to the displacement induced by the new stack item 1210.

In one implementation, a maximum number of stack items can be displayed on the surface 1106. If the addition of a new stack item causes the number of displayed stack items to be exceeded, then a stack item nearest a surface intersection can be displaced from the surface. For example, if the maximum number of stack items to be displayed is four, then the stack item 1208 can continue to move to the edge of the surface 1106, where the stack item 1208 is displaced, e.g., fades from view, atomizes, etc.

In one implementation, the surfaces 1108 and 1112 can, for example, display specific types of desktop items. For example, the surface 1108 can display a file desktop item 1220, e.g., a document icon, and the surface 1112 can display a program desktop item, e.g., an application icon 1222. In one implementation, the file desktop item 1220 corresponds to an open file in an application window 1224, and the application icon 1222 corresponds to the executing application.

In another implementation, a plurality of file desktop items and application desktop items can be displayed on the respective surfaces 1108 and 1112. For example, the surface 1112 can display two icons corresponding to two executing applications. Selection of one of the application icons can, for example, cause corresponding application windows to be displayed on the back surface 1102 and corresponding document icons to be displayed on the surface 1108.

FIG. 13 is a block diagram of another example multidimensional desktop environment. In this example implementation, the back surface 1302 does not include menu items, e.g., menus 1101 and 1103. A stack item 1304 is utilized to access menus corresponding to menus 1101 and 1103 by selecting stack elements 1306 and 1308, respectively. In one implementation, selection of the stack item 1304 and a positioning of the stack item onto the back surface 1302 can cause corresponding menu items 1101 and 1103 to reappear at the top of the back surface 1302.

The multidimensional desktop environment of FIG. 13 can, for example, also facilitate a multidimensional application environment. For example, an application content presentation surface 1310, e.g., an application instance displaying editable data, can be displayed on the back surface 1302, and one or more application control elements can be displayed on one or more side surfaces. For example, a tool bar 1312 can be displayed on the surface 1108 to provide access to toolbar function buttons 1314, 1316, 1318, 1320, 1322 and 1324.

Likewise, menu items 1330 can be displayed on the surface 1112. In one implementation, selection of a menu item generates a textual menu that is axially disposed so that the textual menu appears to be suspended between the back surface 1302 and the viewing surface. For example, selecting the "File" menu from the menu items 1330 can generate the

## 16

floating textual menu 1332, which can, for example, include a shadow effect 1334 on the back surface 1302.

FIG. 14 is a block diagram of another example multidimensional desktop environment. The multidimensional desktop environment of FIG. 14 also facilitates a multidimensional application environment. For example, an application content frame 1410, e.g., a window displaying editable data, can be displayed on the back surface 1102, and one or more application control elements can be displayed on one or more side surfaces. For example, a three-dimensional function icon arrangement 1420 can be displayed on the surface 1108, and menu items 1430 can be displayed on the surface 1112.

The three-dimensional function icon arrangement 1420 can, for example, include three-dimensional function icons 1422, 1424, 1426 and 1428. In one implementation, each three-dimensional function icon 1422, 1424, 1426 and 1428 includes an function command on each surface, and each three-dimensional function icon 1422, 1424, 1426 and 1428 can be rotated, positioned, and manipulated through the use of an input device, such as a mouse.

In an implementation, three-dimensional function icons can be added to the surface 1108 by use of a menu, such as, for example, the "Customize" menu on the surface 1112. In an implementation, a physics model can be applied to model rotation, movement and displacement of the three-dimensional function icons 1422, 1424, 1426 and 1428. For example, removing the three-dimensional function icon 1428 can cause the remaining three-dimensional function icons 1422, 1424 and 1426 to "fall" in a downward direction on the surface 1108.

In an implementation, a three-dimensional login visualization object 1442 can be utilized to facilitate user logins and/or user environments. For example, three sides of the login visualization object 1442 may correspond to login/logout commands for users; and the remaining three sides of the cube can correspond to user environments and/or other user-definable functions for a current user session.

In an implementation, a portal 1440 can be included on a surface, such as the back surface 1102. The portal 1440 can be selected to transition to another multi-dimensional environment. In one implementation, the portal 1440 can facilitate transitioning between different application environments, e.g., between two applications that are currently executing. In another implementation, the portal can facilitate transitioning between different multi-dimensions desktop environments, e.g., from a first environment configured for a work environment to a second environment configured for a leisure environment. In another implementation, the portal 1440 can facilitate transitioning between a two-dimensional desktop environment and a three dimensional desktop environment. Other transitions can also be facilitated by the portal 1440.

FIG. 15 is a block diagram of another example multidimensional desktop environment. In the implementation FIG. 15, windows can be dragged or displaced across one or more surfaces. For example, the stack item 1128 can include stack elements 1503 and 1505 that correspond to windows 1502 and 1504, respectively. In one implementation, selection of a stack element, such as stack element 1503, causes the corresponding window 1502 to transition into view from the surface 1108 and onto the back surface 1102. Likewise, the window 1504, corresponding to the unselected stack element 1505, transitions out of view by sliding across the back surface 1102 and the surface 1112. Other processes to displace, hide, or otherwise deemphasize system objects, such as windows, can also be used.

In an implementation, a stack item 1510 can include stack elements 1512 and 1514 that correspond to portals. For

example, selection of the stack element **1512** can transition the graphical user interface to a two-dimensional desktop, and selection of the stack element **1514** can transition to another application environment.

Additional features can also be realized by other implementations. For example, in one implementation, each surface in the multidimensional desktop environment can implement different behavior and/or functional characteristics. In one implementation, each surface can implement different presentation characteristics. For example, on the bottom surface **1106**, icons and other system object representations can be displayed according to a large scale; on the side surface **1108**, icons and other system object representations can be displayed according to a small scale; on the back surface **1102**, icons and other system object representations can be displayed in a list format; etc. Selecting and dragging an icon or other system object representation from one surface to another will likewise cause the icon and other system object representation to be displayed according to the presentation characteristic of the surface upon which the icon and other system object representation is finally disposed.

In another implementation, a surface can implement a deletion characteristic. For example, the last access time for icons and other system object representations can be monitored. If the last access time for an icon or other system object representation exceeds a first threshold, the icon or other system object representation can be automatically transitioned to the surface implementing the deletion characteristic, e.g., surface **1112**. Additionally, if the last access time for the icon or other system object representation located on the surface **1112** exceeds a second threshold, the icon or other system object representation can be automatically deleted from view.

In one implementation, a configuration tool can be used to facilitate configuration of the surface characteristic of each surface by the user. For example, a configuration menu can present one or more presentation characteristics for associated with one or more surfaces. The one or more presentation characteristics can, for example, be associated by check boxes associated with each surface. Other configuration tools can also be used.

FIG. **16A** is a block diagram of another example multidimensional desktop environment. The multidimensional desktop environment of FIG. **16A** can, for example, implement the features described with respect to FIGS. **2-5** and **7-15**. In the example implementation, the multidimensional desktop environment **1600** includes an arcuate back surface **1602** that is axially disposed, e.g., along the z-axis, from a viewing surface **1604**. In one implementation, a reflection region **1116** can be generated on the side surface **1606**, e.g., the “floor.” In an implementation, the side surfaces **1606**, **1608**, **1610** and **1612** can be defined by arcuate regions having curvature intersections **1607**, **1609**, **1611** and **1613**, respectively.

A curved visualization object receptacle **1614** can include visualization object **1620**, **1622**, **1624** and **1626** and can be positioned on a reflection region **1616**. Stack items **1630** and **1632** can, for example, be positioned near the curvature intersections **1607** and **1609**, respectively. Other arrangements can also be used.

Other multidimensional desktop environment geometries can also be used. For example, in one implementation, the multidimensional desktop environment can conform to a tetrahedron-shaped environment in which a front surface of the tetrahedron defines a viewing surface, and the remaining three surfaces define a left surface, a bottom surface, and a side surface. In another implementation, the multidimensional desktop environment can conform to a triangular environment, in which one axis of the triangle defines the viewing

surface and the remaining two sides of the triangle define a left surface and a right surface. Other geometries can also be used.

In one implementation, a configuration tool can be used to facilitate configuration of the multidimensional desktop environment by the user. For example, a configuration menu can present one or more multidimensional desktop environment geometries for selection by the user, such as a rectangular geometry, an arcuate geometry, a triangular geometry, etc. Selection of a geometry can cause the multidimensional desktop environment to be rendered according to the selected geometry.

FIG. **16B** is a block diagram of another example multidimensional desktop environment. The environment of FIG. **16B** is similar to the environments of FIGS. **2-5** and **7-15** above, except that the back surface **1640** and the floor surface **706** define the desktop environment. The features described above with respect to the floor surface **706** in FIGS. **2-5** can be implemented in the desktop environment of FIG. **16B**.

FIG. **16C** is a block diagram of another example multidimensional desktop environment. The environment of FIG. **16C** is similar to the environment of FIG. **16B** above, except that the back surface **1650** defines the desktop environment. A visualization object receptacle **1652** defining a depth aspect can also be displayed near the bottom of the back surface **1650**. In some implementations, a depth aspect is further emphasized by generating reflections on the surface of the visualization object receptacle **1652**. For example, the visualization objects on the back surface **1650**, e.g., the folder icon **1656** and the application window **1658**, can generate reflections **1654** and **1656** on the surface of the visualization object receptacle **1652**.

In some implementations, the visualization object receptacle **1652** can have a flat height aspect, e.g., the surface of the visualization object receptacle **1652** can appear as a solid flat plane, or a translucent or transparent plane. In other implementations, a height aspect can be generated.

Visualization objects, such as icons **1662**, **1664**, **1666**, **1668**, **1670** and **1672** can be disposed on top of the visualization object receptacle **1652**. In some implementations, a status indicator **1669** can illuminate to indicate a status. For example, the stack item **1668** may correspond to recent downloads, e.g., system updates, documents, etc., and the illumination may be lit to indicate that a download is currently in progress. The status indicator **1669** can, for example, illuminate according to a color code to indicate different status states.

In some implementations, selecting a stack item causes the stack item to expand to display stack elements according to a visualization model, e.g., stack elements **1676**, **1678** and **1680** are displayed according to a matrix arrangement. In some implementations, a collapse widget **1670** can be generated when the contents of a stack item, e.g., stack elements **1676**, **1678** and **1680**, are shown according to a visualization model, and a corresponding visualization frame **1674** that surrounds the stack elements **1676**, **1678** and **1680** can be displayed.

In some implementations, selection of a “Show in Finder” command object **1682** can display a Finder window for a folder containing the stack items **1676**, **1678** and **1680** if the stack items **1676**, **1678** and **1680** are stored in a common folder. In another implementation, selection of a “Show in Finder” command object **1682** can display a Finder window containing the stack items **1676**, **1678** and **1680** even if the stack items **1676**, **1678** and **1680** are not stored in a common folder.

In some implementations, a stack item collection process can identify visualization objects on a desktop and collapse the objects into a stack item. For example, the application windows **1658** and **1659** can be identified and collapsed into a stack item. In some implementations, the collapsing of visualization objects includes an animation effect, e.g., a “genie” effect; a “tornado” effect, etc.

In some implementations, textual strings associated with the visualization objects, e.g., filenames associated with icons, can be centrally truncated. A centrally truncated string displays the beginning of the textual string and the end of the textual string. In some implementations, a file extension can be shown by the central truncation. In other implementations, the file extension can be omitted. Positioning a cursor on the textual string, or on the visualization object associated with the textual string, can cause the entire textual string to be displayed. For example, as shown in FIG. **16C**, the textual string **1677**, i.e., “Movie of Page’s birthday.mpg” is truncated to “Mov . . . day.mpg.” Conversely, the textual string **1679**, i.e., “Movie of Julia.mpg,” which is positioned beneath a cursor, is fully displayed.

FIG. **16D** is a block diagram of another example multidimensional desktop environment. The environment of FIG. **16C** is similar to the environment of FIG. **16B** above, except that a fanning visualization model is displayed for the stack items **1676**, **1678** and **1680**. In the implementation shown, document titles related to the stack items **1676**, **1678** and **1680** are displayed proximate to the stack items. In some implementations, textual strings associated with visualization objects, e.g., filenames of icons, are fully displayed in the fanning visualization model.

FIG. **17** is a block diagram of an example desktop transition. In one implementation, a computer system, such as the system **100** of FIG. **1**, can be configured to transition between a two-dimensional desktop **1702** and a three-dimensional desktop **1730**. For example, the two dimensional desktop **1702** defines a viewing surface **1703** and includes folders **1704**, **1706**, **1708** and **1710**, an icon **1712** corresponding to a hard drive, and icon **1714** corresponding to a network, and an icon display region **1720** that displays a plurality of icons **1722**.

In response to a transition command, the system can, for example, depth transition the two-dimensional desktop **1702** from the viewing surface **1703** to define a back surface **1732**, and one or more side surfaces, such as side surfaces **1706**, **1708** and **1710**, can extend from the back surface **1732** to the viewing surface **1703**. A visualization object receptacle **1730** can be generated on the surface **1706**, and one or more icons **1732** corresponding to desktop items can be disposed in the visualization object receptacle. In the example implementation of FIG. **17**, the icons **1732** correspond to the icons **1722**.

In one implementation, stack items, such as stack items **1742**, **1744**, **1746** and **1748**, can be generated from two dimensional desktop items, such as desktop folders **1704**, **1706**, **1708** and **1710**. The two dimensional desktop items can, for example, be eliminated from the back surface **1732**. In one implementation, two-dimensional desktop items that are not represented by a corresponding icon after the transition to the three-dimensional desktop **1730** can, for example, remain on the back surface **1732**. For example, the icons **1712** and **1714** can remain on the back surface **1732**. In another implementation, the two-dimensional desktop items that are not represented by a corresponding icon after the transition to the three-dimensional desktop **1730** can, for example, be eliminated from the back surface **1732**. In another implementation, the two-dimensional desktop items that are not represented by a corresponding icon after the transition to the

three-dimensional desktop **1730** can, for example, be eliminated from the back surface **1732** and represented by corresponding stack elements in a “catch all” stack item, such as stack item **1750**.

The transition from the two-dimensional desktop **1702** to a three-dimensional desktop **1730** can be substantially reversed to transition from the three-dimensional desktop **1730** to the two-dimensional desktop **1702**.

FIG. **18A** is a block diagram of an example visualization object receptacle indicator. An example visualization object receptacle **1802** includes visualization objects, e.g., icons **1804**, **1806**, **1808**, **1810**, **1812** and **1814**. In an implementation, a selection indicator **1820** can be used to indicate a selected icon. In one implementation, the selection indicator **1820** is generated by an under-lighting effect that illuminates the surface of the visualization object receptacle **1802** below a selected icon, such as the icon **1806**. Other selection indicators can also be used, such as selection status indicator **1821**, or backlighting effects, outlining effects, or other indicators.

FIG. **18B** is a block diagram of another example visualization object receptacle indicator. In an implementation, a selection indicator **1822** can be used to indicate a selected icon. In one implementation, the selection indicator **1822** is generated by an enlargement of a selected icon, such as icon **1806**, relative to adjacent icons, and an under-lighting effect that illuminates the surface of the visualization object receptacle **1802** below a selected icon **1806** and adjacent icons **1804** and **1808**. In an implementation that includes a selection status indicator **1821**, the selection status indicator **1821** can expand into a large selection status indicator **1823**.

FIG. **18C** is a block diagram of another example visualization object receptacle indicator. In an implementation, a selection indicator **1824** can be used to indicate a selected icon. In one implementation, the selection indicator **1824** is generated by an enlargement of a selected icon, such as icon **1806**, relative to adjacent icons, and a backlighting effect that illuminates the surface of the visualization object receptacle **1802** below a selected icon **1806** and illuminates adjacent icons **1804** and **1808**.

FIG. **18D** is a block diagram of another example visualization object receptacle indicator. The visualization object receptacle **1802** can, for example, include one or more status indicators to indicate the status of a system object associated with one or more icons. For example, a status indicator **1830** indicating an unselected and executing application can be generated by an under-lighting effect of a first color; a status indicator **1832** indicating a selected and executing application can be generated by an under-lighting effect of a first color; and a status indicator **1834** indicating a launching application can be generated by an under-lighting effect of a third color.

Other status indicator schemes can also be used. For example, in one implementation, a status indicator **1834** indicating a launching application can be generated by a pulsing under-lighting effect. In another implementation, status indicators can indicate a status by an intensity; for example, an icon corresponding to an open document, e.g., a document icon, a stack item, or an application icon, can be backlit with a relatively high intensity, and an icon corresponding to an open and unselected document can be backlit with a relatively low intensity. For example, in implementations utilizing status indicators **1831**, **1833** and **1835**, the status indicators can be illuminated according to a similar color scheme.

FIGS. **19A** and **19B** are block diagrams of an example contextual menu for a visualization object receptacle **1802**. In some implementations, a selectable divet **1902** can be dis-

## 21

played proximate to an icon, e.g., icon **1804**, to indicate an actionable state associated with a system object represented by the icon **1804**. For example, if the icon **1804** is representative of a system update process or program, the selectable divet **1902** can be displayed when a system update is available.

The selectable divet **1902** can, for example, be a floating orb proximate to the icon **1804**. Other shapes or visual representations can also be used. In some implementations, the selectable divet **1902** is color coded according to a color code to indicate corresponding actionable states.

FIG. **19B** illustrates an example contextual menu **1910** that can be displayed proximate to the icon **1804** in response to a selection of the selectable divet **1902**. The contextual menu **1910** can include one or more menu options, e.g., menu options **1912** and **1914**, related to the icon **1804**. In some implementations, the divet **1902** remains until a necessary action is taken. In other implementations, the divet **1902** can be removed by a corresponding selection of one of the menu options in the contextual menu **1910**. In some implementations, the divet **1902** can fade from view if it is not selected after a period of time, e.g., 30 minutes.

FIG. **20** is a block diagram of a visualization object receptacle including type-ahead indications. In some implementations, one or more highlight indicators **2000**, **2002** and **2004**, and/or **2001**, **2003** and **2005** are generated in response to type input data, e.g., data generated by keyboard inputs. The one or more highlight indicators **2000**, **2002** and **2004**, and/or **2001**, **2003** and **2005** can be generated for icons having textual descriptions corresponding to the keyboard inputs, and can be adjusted in response to the type input data so that only icons having textual descriptions defined by the type input data are highlighted. For example, if the textual descriptions of the icons **1804**, **1810** and **1812** are "Clock," "Calculator," and "Classics," then the highlight indicators **2000**, **2002** and **2004**, and/or **2001**, **2003** and **2005** would illuminate in response to the keyboard input "c." A subsequent keyboard input "l" would cause the highlight indicators **2002** and/or **2003** to turn off; and a third keyboard input "o" would cause the highlight indicators **2004** and/or **2005** to turn off. According, the icon **1804**, corresponding to the textual description "clock" would be selected by the type input data c, l and o.

Other selection indications based on type input can be used. For example, stack elements from a stack item can disappear in response to type input. Thus, if a stack item includes stack elements entitled "Clock," "Calculator," "Classics," "Movies," and "Safari," the keyboard input "c" would cause the "Movies" and "Safari" visualization object to disappear. A subsequent keyboard input "a" would cause the "Clock" and "Classics" visualization objects to disappear.

In addition to selections based on a textual description beginning with the type input data, selections based on the type input data can also be based on whether the textual description of the visualization object contains the text input or ends with text. For example, all stack elements having .mac extensions can be visualized by selecting an "Ends with" type input option and entering the type input "m," "a" and "c."

FIGS. **21A** and **21B** are block diagrams of example selection indicators for a visualization model. In FIG. **21A**, stack elements **2104**, **2106**, **2108**, **2110**, **2112**, and **2114** are displayed according to a visualization model, e.g., a matrix arrangement. One or more highlight indicators **2109** and **2111**, e.g., focus rings, can be generated in response to keyboard input data. The focus rings **2109** and **2111** can be adjusted in response to the type of input data so that only visualization objects having textual descriptions defined by the type input data are highlighted, as described with respect

## 22

to FIG. **20** above. For example, the focus rings **2109** and **2111** can be generated in response to the keyboard input "c." A subsequent keyboard input "l" would cause the focus ring **2111** to fade from view.

In FIG. **21B**, stack elements **2104**, **2106**, **2108**, **2110**, **2112**, and **2114** are displayed according to a visualization model, e.g., a matrix arrangement. In this implementation, a highlight indicator is generated based on a cursor position. For example, if a mouse cursor **2120** is first positioned over the visualization object **2110**, a first focus ring **2111** can be generated completely or partially around the visualization object **2110**. However, if the mouse cursor **2120** is moved to a position over the visualization object **2108**, the first focus ring **2111** will fade from view and a second focus ring **2109** will be generated around the visualization object **2108**.

In some implementations, the focus ring persists around a visualization object until the mouse cursor **2120** is positioned over another visualization object. In some implementations, the focus ring persists around a visualization object only when the mouse cursor **2120** is positioned over the visualization object. Other processes for generating and removing selection indicators can also be used.

FIG. **22** is a block diagram of another example multidimensional desktop environment. In an implementation, an indicator can, for example, be used to indicate representations of system objects having an association. For example, the icon **2206**, the stack item **2208**, the folder **2210** and the window **2212** can be related by having corresponding system objects related to, for example, an application, e.g., the icon **2206** can be the application icon; the stack item **2208** can provide access to particular documents related to the application; the folder **2210** can define a data store storing all application documents; and the window **2212** can be an instance of the executing application. In one implementation, selection of any one of the icon **2206**, stack item **2208**, folder **2210** or window **2212** can generate a common selection indicator for all items. The common selection indicator can, for example, be realized by a lighting effect, such as a backlighting effect, by a temporary pulsing effect, or by some other permanent or transient effect.

FIG. **23** is a block diagram of another example visualization object receptacle **2302**. The example visualization object receptacle **2302** includes a plurality of visualization object rows **2312** and **2314** and a plurality of visualization object columns **2322**, **2324**, **2326**, **2328**, **2330** and **2323**. In an implementation, the visualization object receptacle **2302** includes a plurality of visualization objects **2304** disposed within the visualization object receptacle **2302** according to the visualization object rows **2312** and **2314** and visualization object columns **2322**, **2324**, **2326**, **2328**, **2330** and **2323**.

Although two visualization object rows and six visualization object columns are shown, the visualization object receptacle can include additional or fewer visualization object rows and visualization object columns. In an implementation, a subset of the visualization object rows and visualization object columns can, for example, be visible at any one time.

The visualization object rows and visualization object columns can, for example, be traversed by shifting the rows and/or columns in unison, as indicated by the solid arrows. For example, when a cursor is positioned on the visualization object receptacle, such as the cursor in the position defined by the intersection of the visualization object row **2312** and the visualization object column **2332**, a command (e.g., a control-click command) can cause the visualization object rows and/or columns to shift in unison in response to movement of the cursor. In another implementation, each visualization object row and visualization object column can, for example,

## 23

be traversed individually by shifting a particular row or column, as indicated by the dashed arrows. For example, when the cursor is positioned on the visualization object receptacle **2302**, an option-click command can cause the corresponding visualization object row **2312** and/or the corresponding column **2332** to shift individually in response to movement of the cursor. Other visualization object receptacle navigation schemes can also be used.

FIG. **24** is a block diagram of an example stack item **2400**. The stack item **2400** includes a plurality of stack elements **2402**, **2404**, **2406**, **2408** and **2410**, each corresponding to one or more system objects. In one implementation, a boundary **2420** defined by the stack elements **2402**, **2404**, **2406**, **2408** and **2410** defines an inclusion region that is associated with the stack item **2400**. In one implementation, placement of an icon within the inclusion region generates a stack element associated with the icon. Likewise, placement of a stack element without the inclusion region disassociates the stack element with the stack item **2400**. In another implementation, the inclusion region can be separate from the stack item.

In some implementations, the display size of the stack item **2400** can change according to a state. For example, if a system object corresponding to a stack element in the stack item **2400** requires attention, the size of the stack item **2400** is adjusted to be rendered at a larger display size. Likewise, positioning a mouse cursor over the stack item **2400** can cause the stack item **2400** to be rendered at a larger display size.

In some implementations, the stack item **2400** can change orientation and or appearance according to a state. For example, positioning a mouse cursor over the stack item **2400** can cause the stack item **2400** to rotate, or can cause stack elements in the stack item **2400** to randomly shuffle.

FIG. **25** is a block diagram of another example stack item **2500**. The stack item **2500** includes a plurality of stack elements **2502**, **2504**, **2506**, **2508** and **2510**, each corresponding to a document system object. In one implementation, stack elements **2502**, **2504**, **2506**, **2508** and **2510** display a corresponding unique indicium, e.g., a thumbnail preview of an image associated with the stack element or the first page of a document associated with the stack element. Other unique indicium or unique indicia can also be used, such as correspondence to an aspect ratio of an image, displaying of a document size and/or a document date can be displayed in each stack element **2502**, **2504**, **2506**, **2508** and **2510**, etc.

FIG. **26** is a block diagram of another example stack item **2600**. The stack item **2600** includes a plurality of stack elements **2602**, **2604**, **2606**, **2608** and **2610**. The stack element **2602** corresponds to an application icon of an application system object, and the stack element **2604**, **2606**, **2608** and **2610** correspond to document system objects. In one implementation, the stack item **2602** can, for example, be preeminently disposed with respect to the stack elements **2604**, **2606**, **2608**, and **2610**. For example, the stack item **2602** can be permanently placed on the top of the aggregation of stack elements **2604**, **2606**, **2608** and **2610**. Thus, a shifting of a location of a stack element within the stack item **2600**, such as by selecting the stack element **2612** and placing the stack element **2612** on top of the stack element **2602**, or an addition of a new stack element, will not displace the stack element **2602** from the preeminent position.

Other methods of preeminently disposing a stack element related to an application icon can also be used. FIG. **27**, for example, is a block diagram of another example stack item **2700** in which the stack element **2602** is preeminently disposed by enlarging the application element **2602** relative to the stack elements **2604**, **2606**, **2608** and **2610**. In another implementation, the stack elements **2604**, **2606**, **2608** and

## 24

**2610** can be rendered with a translucent effect, and the stack element **2602** can be rendered with an opaque effect so that the entirety of the stack element **2602** is discernable no matter the position of the stack element **2602** in the stack item.

FIG. **28A** is a block diagram of example stack items **2802**, **2804** and **2806** that are color-coded. In the example implementation of FIG. **28A**, instantiation of each stack item **2802**, **2804** and **2806** can be subject to a temporal context and color-coded accordingly. For example, the temporal context can define date ranges, and the stack items **2802**, **2804** and **2806** can be associated with each date range and color-coded accordingly, e.g., green for the date range "Today," yellow for the date range "Last Week," and red for the date range "Last Month."

In one implementation, a stack element associated with a system object is further associated with a stack item if a relevant date associated with the system object is within the date range associated with the stack item. For example, if the stack items **2802**, **2804** and **2806** are utilized to provide access to word processing document system objects based on a "last modified" date, then the stack elements in the stack item **2802** corresponds to word processing documents modified today; the stack elements in the stack item **2804** corresponds to word processing documents modified within the last week; and the stack elements in the stack item **2806** corresponds to word processing documents modified within the last month.

FIG. **28B** is a block diagram of an example stack items **2810** that is color-coded. In the implementation of FIG. **28B**, stack elements **2820**, **2822**, **2824**, **2830**, **2832**, **2840** and **2842** are color coded according to a temporal context. For example, the stack elements **2820**, **2822** and **2824** are color-coded to identify system objects added during a current day; the stack elements **2830** and **2832** are color-coded to identify system objects added during the last week; and stack elements **2840** and **2842** are color-coded to identify system objects added during the last month. Other color-coding schemes can also be used, e.g., application type, last modified, file size, or even user defined settings.

FIG. **29** is a block diagram illustrating an example contextual control scheme applied to an example stack item **2900**. For example, the contextual control can be an application context **2910** that defines an executing and selected state **2912**, an executing and non selected state **2914**, and a not executing state **2916**. An executing and selected state **2912** can occur, for example, when an application window of an executing or launching application is selected. An executing and not selected state **2914** can occur, for example, when another process other than the application is selected. A not executing state **2916** can occur, for example, when execution of an application is terminated. In one implementation, the stack item is displayed during the executing and selected state **2912**; is minimized, e.g., deemphasized, during the executing and not selected state; and is suppressed, e.g., unallocated or hidden from view during the not executing state **2916**.

Other types of contextual control can also be used. For example, contextual control based on a user level associated with system objects, such as a root user level or supervisor level, can control instantiation of a stack item and/or instantiation of stack elements within the stack item, and can, for example, further control commands available to the user.

FIG. **30** is a block diagram illustrating the application of an example visualization model to an example stack item **3000**. The visualization model can, for example, be implemented according to first and second modal states. In the first modal state, the stack item **3000** is displayed with the stack elements **3002**, **3004**, **3006**, **3008** and **3010** in a substantially overlap-

## 25

ping arrangement. In a second modal state, the stack elements **3002**, **3004**, **3006**, **3008** and **3010** are displayed according to an automatically selected visualization model. The visualization model can be selected as described above.

The example visualization model illustrated in FIG. **30** can, for example, define a multidimensional path defined by a first terminus **3020** and a second terminus **3022**, and generates a disposition of the stack elements **3002**, **3004**, **3006**, **3008** and **3010** along the multidimensional path. For example, the stack elements **3002**, **3004**, **3006**, **3008** and **3010** can transition in either direction between the first terminus **3020** and the second terminus **3022** in response to a user input.

In one implementation, an indicator can indicate a preeminent disposition of a stack element. For example, the stack item **3002** can be highlighted by a focus ring when in the preeminent position defining the first terminus **3020**.

FIG. **31A** is a block diagram illustrating another example visualization model for an example stack item **3100**. The visualization model can, for example, be implemented according to first and second modal states as described with respect to FIG. **30**. In the second modal state, the stack elements **3102**, **3104**, **3106** and **3108** are displayed according to an automatically selected visualization model that generates an arrangement of the stack elements **3102**, **3104**, **3106** and **3108** in substantial juxtaposition. The stack elements **3002**, **3004**, **3006** and **3008** can, for example, transition along a circular path defined by the circular trace common to the stack elements **3102**, **3104**, **3106** and **3108**.

In one implementation, an indicator can indicate a preeminent disposition of a stack element. For example, the stack item **3002** can be highlighted by a focus ring when in the preeminent position defined by the upper left quadrant position.

FIG. **31B** is a block diagram illustrating the application of another example visualization model to an example stack item **3120**. The visualization model is similar to the visualization model of FIG. **31A**, except that the stack elements **3122**, **3124**, **3126**, **3128**, **3130** and **3132** can traverse corresponding paths to be displayed in a display matrix. While the paths shown in FIG. **31B** are curved, other paths can also be used, e.g., straight paths, corkscrew paths, sinusoidal paths, or combinations of such paths.

FIG. **32** is a block diagram illustrating the application of another example visualization model to an example stack item **3200**. The stack item **3200** can, for example, include dozens, hundreds or even thousands of stack items. For example, the stack elements **3202**, **3204**, **3206**, **3208**, and **3210** may be displayed as opaque stack elements, and the stack element **3212** can be displayed as a translucent stack element, or can be a final stack element near a vanishing point.

The visualization model can, for example, be implemented according to first and second modal states as described with respect to FIG. **30**. In the second modal state, a subset of all the stack elements, e.g., stack elements **3202**, **3204**, **3206**, **3208**, and **3210** are displayed according to an automatically selected visualization model that generates an arrangement of the stack elements in a list view format. A navigation control **3220** can, for example, be displayed proximate to the arrangement of stack elements, and a selection of either an “up” directional portion **3222** or a “down” directional portion **3224** can cause the stack elements to traverse through the list view format in an up or down direction, respectively. For example, selecting the “down” directional portion **3224** will cause the stack element **3202** to be removed from the list view display, cause the stack elements **3204**, **3206**, **3208** and **3210** to move

## 26

down in the list view display, and cause the stack element **3212** to appear at the top of the list view display.

Selection of a navigation divet **3226** can generate a contextual menu that includes one or more sort commands. Example sort commands include sorting by date added, sorting by file size, sorting by file type, etc.

In the implementation of FIG. **32**, the list view traverses an actuate path as indicated by the curved arrow **3230**, e.g., a model of a curved surface that is normal to the viewing plane at the central stack element, e.g., stack element **3206**. Accordingly, stack elements that are not normal to the viewing surface, e.g., stack elements **3202**, **3204**, **3208** and **3210**, include a curvature distortion defined by the curved surface. Other list view formats can also be used, e.g., a straight path in which the stack elements are not distorted.

In some implementations, a user interface engine, e.g., the UI engine **202** of FIG. **2**, can pre-cache display data for a subset of the stack elements displayed in the list view format. The pre-caching can be limited to stack elements that are within a certain number of stack elements to be displayed in the list view. For example, the stack element **3200** may include thousands of photograph image files; the UI engine **202**, however, may only pre-cache thumbnail images of the next five stack elements to be displayed by selection of the “up” directional portion **3222** and “down” directional portion **3224**, respectively.

In another implementation, a stack item, upon selection, may rotate to a side and present the stack elements as a series of graphical representations of book spines, e.g., such as in a book shelf. Depending on the number of stack elements, the book shelf may be one level, multiple levels, or may be extend into a vanishing point and be traversed in response to a user input. Visualization object can be “pulled” from the bookshelf in response to a user input, e.g., a mouse command or a mouse hover, and a subsequent command, e.g., a mouse click, can open a file associated with the visualization object. Other visualization models can also be used.

FIG. **33A** is a block diagram of an example group association **3300** of an example stack item **3310**. The group association **3300**, can, for example, be based one or more identified association characteristics of the stack elements **3312**, **3314**, **3316** and **3318**. For example, the group association **3300** can comprise a project association, e.g., files associated with a presentation developed with a first project application **3302** and which utilizes data from files associated with a second project application **3304**.

In one implementation, an interaction model can be selected based on the project association. In an implementation, a multiple launch interaction model can be selected when any one of the system objects related to the stack elements **3312**, **3314**, **3316** and **3318** is opened. In one implementation, the multiple launch interaction model can, for example, confirm a launching of both applications **3302** and **3304**. In another implementation, the multiple launch interaction model can, for example, provide a context menu in which either or both of the applications **3302** and **3304** can be selected for launching. Other multiple launching interaction models can also be used.

In another implementation, a synchronization interaction model can be selected when one of the system objects related to the stack elements **3312**, **3314**, **3316** and **3318** is saved to a data store, such as a hard disk. The synchronization interaction model can, for example, provide one or more contextual menus or other interaction aspects to prompt a user to synchronize all stack elements when any one of the stack elements has been updated. Other synchronization interaction models can also be used.

In another implementation, a reconciliation interaction model can be selected when one of the system objects related to the stack elements **3312**, **3314**, **3316** and **3318** is changed, e.g., a file association with the stack element **3312** is replaced by a new file. The reconciliation interaction model can, for example, provide one or more contextual menus or other interaction aspects to prompt a user to reconcile all stack elements when any one of the stack elements are replaced. Other reconciliation interaction models can also be used.

Interaction and/or visualization models can also be applied to other representations of system objects. For example, in one implementation, the system objects can include window instances in the multidimensional desktop environment, and the association characteristics can include a quantity of non-minimized window instances. Accordingly, an interaction model can be automatically selected for facilitating operations on the open windows, depending on the number of open windows. For example, if the number of open windows is greater than five, selection of a browse command can cause the open windows to be automatically displayed in an overlapping arrangement for browsing; and if the number of open windows is less than five, selection of the browse command can cause the open windows to be automatically displayed in a matrix arrangement for browsing.

FIG. **33B** is a block diagram of an example group association of system objects. The group association **3350**, can, for example, be based one or more identified association characteristics of the system objects, such as documents **3360**, **3362** and **3364**. The group association **3350** can, for example, be utilized to select one or more visualization and/or interaction models as described above. However, the documents **3360**, **3362** and **3364** need not be associated in a stack item, e.g., the documents **3360**, **3362** and **3364** can each be associated with different stack items, or not associated with any stack items.

FIG. **34** is a flow diagram of an example process **3400** for transitioning a desktop. The process **3400** can, for example, be implemented in a processing device, such as the system **100** of FIG. **1**, implementing user interface software and/or hardware, such as the example implementations described with respect to FIGS. **2**, **5** and **6**.

Stage **3402** depth transitions a two-dimensional desktop from a viewing surface to a back surface. For example, the system **100**, implementing any one of the UI engines described in FIGS. **2**, **5** and **6**, can depth transition a two-dimensional desktop, such as the desktop **1702** of FIG. **17**, from a viewing surface to a back surface, such as from the viewing surface **1703** to the back surface **1732** as shown in FIG. **17**.

Stage **3404** generates one or more side surfaces extending from the back surface to the viewing surface. For example, the system **100**, implementing any one of the UI engines described in FIGS. **2**, **5** and **6**, can generate one or more side surfaces extending from the back surface to the viewing surface, such as the side surfaces **1706**, **1708** and **1710** of FIG. **17**.

Stage **3406** generates a visualization object receptacle, e.g., an icon receptacle, on the one or more side surfaces. For example, the system **100**, implementing any one of the UI engines described in FIGS. **2**, **5** and **6**, can generate an icon receptacle on the one or more side surfaces, such as the visualization object receptacle **1730** on the surface **1706** of FIG. **17**.

Stage **3408** disposes one or more visualization object, e.g., icons, corresponding to desktop items within the visualization object receptacle. For example, the system **100**, implementing any one of the UI engines described in FIGS. **2**, **5** and **6**, can dispose one or more icons corresponding to desktop

items within the visualization object receptacle, such as the icons **1732** in the visualization object receptacle **1730**, which correspond to the icons **1722** of FIG. **17**.

FIG. **35** is a flow diagram of another example process **3500** for transitioning between desktop types. The process **3500** can, for example, be implemented in a processing device, such as the system **100** of FIG. **1**, implementing user interface software and/or hardware, such as the example implementations described with respect to FIGS. **2**, **5** and **6**.

Stage **3502** identifies two-dimensional desktop items in a two-dimensional desktop environment. For example, the system **100**, implementing any one of the UI engines described in FIGS. **2**, **5** and **6**, can identify two-dimensional desktop items in a two-dimensional desktop environment, such as the folders **1704**, **1706**, **1708** and **1710** of FIG. **17**.

Stage **3504** generates three-dimensional desktop items based on the identified two-dimensional desktop items. For example, the system **100**, implementing any one of the UI engines described in FIGS. **2**, **5** and **6**, can generate three-dimensional desktop items based on the identified two-dimensional desktop items, such as the stack items **1742**, **1744**, **1746** and **1748** of FIG. **17**, which correspond to the folders **1704**, **1706**, **1708** and **1710**.

Stage **3506** eliminates the two-dimensional desktop items from view. For example, the system **100**, implementing any one of the UI engines described in FIGS. **2**, **5** and **6**, can eliminate two-dimensional desktop items from view, such as the elimination of the folders **1704**, **1706**, **1708** and **1710** from the back surface **1732** of FIG. **17**.

Stage **3508** generates the three-dimensional desktop items on at least one surface (e.g., a side surface). For example, the system **100**, implementing any one of the UI engines described in FIGS. **2**, **5** and **6**, can generate the three-dimensional desktop items on at least one side surface, such as the stack items **1742**, **1744**, **1746** and **1748** on the bottom side surface **1706** of FIG. **17**.

FIG. **36** is a flow diagram of an example process **3600** for generating a multidimensional desktop environment. The process **3600** can, for example, be implemented in a processing device, such as the system **100** of FIG. **1**, implementing user interface software and/or hardware, such as the example implementations described with respect to FIGS. **2**, **5** and **6**.

Stage **3602** axially disposes a back surface from a viewing surface. For example, the system **100**, implementing any one of the UI engines described in FIGS. **2**, **5** and **6**, can axially dispose a back surface from a viewing surface, such as the back surface **1102** being axially disposed from the viewing surface **1104**, as shown in FIG. **11**.

Stage **3604** extends one or more side surfaces from the back surface to the viewing surface. For example, the system **100**, implementing any one of the UI engines described in FIGS. **2**, **5** and **6**, can extend one or more side surfaces from the back surface to the viewing surface, such as the side surfaces **1106**, **1108**, **1110** and **1112**, as shown in FIG. **11**.

Stage **3606** generates a visualization object receptacle on one or more of the side surfaces. For example, the system **100**, implementing any one of the UI engines described in FIGS. **2**, **5** and **6**, can generate an icon receptacle on one or more of the side surfaces, such as the visualization object receptacle **1114** on the side surface **1106**, as shown in FIG. **11**.

Stage **3608** generates within the visualization object receptacle one or more visualization objects, e.g., icons, corresponding to one or more system objects. For example, the system **100**, implementing any one of the UI engines described in FIGS. **2**, **5** and **6**, can generate within the visualization object receptacle one or more icons corresponding

to one or more system objects, such as the icons **1120**, **1122**, **1124**, **1126**, **1128** and **1130** as shown in FIG. 11.

FIG. 37 is a flow diagram of an example process **3700** for rendering a side surface in a multidimensional desktop environment. The process **3700** can, for example, be implemented in a processing device, such as the system **100** of FIG. 1, implementing user interface software and/or hardware, such as the example implementations described with respect to FIGS. 2, 5 and 6.

Stage **3702** generates stack items on a surface (e.g., a side surface). For example, the system **100**, implementing any one of the UI engines described in FIGS. 2, 5 and 6, can generate stacks items on a side surface, such as the stack items **1140**, **1142**, **1144** and **1146** generated on the side surface **1106**, as shown in FIG. 11.

Stage **3704** renders a surface texture on the surface. For example, the system **100**, implementing any one of the UI engines described in FIGS. 2, 5 and 6, can render a surface texture on the side surface, such as the grid texture **1150** on the side surface **1106**, as shown in FIG. 11.

FIG. 38 is a flow diagram of an example process **3800** for scrolling a side surface in a multidimensional desktop environment. The process **3800** can, for example, be implemented in a processing device, such as the system **100** of FIG. 1, implementing user interface software and/or hardware, such as the example implementations described with respect to FIGS. 2, 5 and 6.

Stage **3802** scrolls the side surface in response to a scroll command. For example, the system **100**, implementing any one of the UI engines described in FIGS. 2, 5 and 6, can scroll the side surface in response to a scroll command, such as the side surface **1106** in the directions indicated by one or more of the arrows **1152** and **1154**, as shown in FIG. 11.

Stage **3804** scrolls the stack items in a scroll direction. For example, the system **100**, implementing any one of the UI engines described in FIGS. 2, 5 and 6, can scroll the stack items in a scroll direction, such as the stack items **1140**, **1142**, **1144** and **1146** in the directions indicated by one or more of the arrows **1152** and **1154**, as shown in FIG. 11.

Stage **3806** displaces a stack item(s) from the side surface at a scroll egress. For example, the system **100**, implementing any one of the UI engines described in FIGS. 2, 5 and 6, can displace a stack item(s) from the side surface at a scroll egress, such as the scroll egress **1158** (or **1159**), as shown in FIG. 11.

Stage **3808** emplaces a stack item(s) on the side surface at a scroll ingress. For example, the system **100**, implementing any one of the UI engines described in FIGS. 2, 5 and 6, can emplace a stack items on the side surface at a scroll ingress, such as the scroll ingress **1156** (or **1157**) as shown in FIG. 11.

FIG. 39 is a flow diagram of an example process **3900** for generating a selection indicator. The process **3900** can, for example, be implemented in a processing device, such as the system **100** of FIG. 1, implementing user interface software and/or hardware, such as the example implementations described with respect to FIGS. 2, 5 and 6.

Stage **3902** generates an under lighting effect as the selection indicator. For example, the system **100**, implementing any one of the UI engines described in FIGS. 2, 5 and 6, can generate an under lighting effect as the selection indicator, such as the selection indicator **1822** of FIG. 18B.

Stage **3904** generates an enlargement effect as the selection indicator. For example, the system **100**, implementing any one of the UI engines described in FIGS. 2, 5 and 6, can generate an enlargement effect as the selection indicator, such as the enlargement of the stack indicator **1806** as shown in FIG. 18B.

FIG. 40 is a flow diagram of an example process **4000** for rendering desktop items. The process **4000** can, for example, be implemented in a processing device, such as the system **100** of FIG. 1, implementing user interface software and/or hardware, such as the example implementations described with respect to FIGS. 2, 5 and 6.

Stage **4002** generates stack items on a first side surface corresponding to a plurality of desktop items. For example, the system **100**, implementing any one of the UI engines described in FIGS. 2, 5 and 6, can generate stack items on a first side surface corresponding to a plurality of desktop items, such as the stack items **1202**, **1204**, **1206**, **1208** and **1212**, and the visualization object receptacle **1114** and icons **1122**, **1124**, **1126**, **1128**, **1130** and **1132** as shown in FIG. 12.

Stage **4004** generates icons corresponding to program items on a second side surface. For example, the system **100**, implementing any one of the UI engines described in FIGS. 2, 5 and 6, can generate icons corresponding to program items on a second side surface, such as the application icon **1222** on the surface **1112**, as shown in FIG. 12.

Stage **4006** generates icons corresponding to file items on a third side surface. For example, the system **100**, implementing any one of the UI engines described in FIGS. 2, 5 and 6, can generate icons corresponding to file items on a third side surface, such as the file desktop item **1220** on the surface **1108** of FIG. 12.

FIG. 41 is a flow diagram of an example process **4100** for generating an example application environment in a multidimensional desktop environment. The process **4100** can, for example, be implemented in a processing device, such as the system **100** of FIG. 1, implementing user interface software and/or hardware, such as the example implementations described with respect to FIGS. 2, 5 and 6.

Stage **4102** axially disposes a back surface from a viewing surface. For example, the system **100**, implementing any one of the UI engines described in FIGS. 2, 5 and 6, can axially dispose a back surface from a viewing surface, such as the back surface **1102** that is axially disposed from the viewing surface in FIG. 14.

Stage **4104** extends one or more side surfaces from the back surface to the viewing surface. For example, the system **100**, implementing any one of the UI engines described in FIGS. 2, 5 and 6, can extend one or more side surfaces from the back surface to the viewing surface, such as the side surfaces **1106**, **1108**, and **1112**, as shown in FIG. 14.

Stage **4106** generates an application content frame for an application on the back surface. For example, the system **100**, implementing any one of the UI engines described in FIGS. 2, 5 and 6, can generate an application content frame for an application on the back surface, such as the application content frame **1410** on the back surface **1102**, as shown in FIG. 14.

Stage **4108** generates one or more application control elements for the application on the one or more side surfaces. For example, the system **100**, implementing any one of the UI engines described in FIGS. 2, 5 and 6, can generate one or more application control elements for the application on the one or more side surfaces, such as the function icons **1422**, **1424**, **1426** and **1428**, as shown in FIG. 14. The application control elements, e.g., the function icons **1422**, **1424**, **1426** and **1428**, can be used to control functions of the application, such as editing commands for an editing environment displayed in an application content frame on the back surface.

FIG. 42 is a flow diagram of an example process **4200** for transitioning between application environments. The process **4200** can, for example, be implemented in a processing device, such as the system **100** of FIG. 1, implementing user

interface software and/or hardware, such as the example implementations described with respect to FIGS. 2, 5 and 6.

Stage **4202** generates an application portal on one of the side surfaces. For example, the system **100**, implementing any one of the UI engines described in FIGS. 2, 5 and 6, can generate an application portal on one of the side surfaces, such as the stack item **1510** that includes stack elements **1512** and **1514** that correspond to portals, as shown in FIG. 15.

Stage **4204** transitions from a first application environment to a second application environment in response to a selection of the application portal. For example, the system **100**, implementing any one of the UI engines described in FIGS. 2, 5 and 6, can transition from a first application environment to a second application environment in response to a selection of the application portal. As described with respect to FIG. 15, selection of the stack element **1514** can transition to another application environment.

FIG. 43 is a flow diagram of an example process **4300** for generating a visualization object receptacle. The process **4300** can, for example, be implemented in a processing device, such as the system **100** of FIG. 1, implementing user interface software and/or hardware, such as the example implementations described with respect to FIGS. 2, 5 and 6.

Stage **4302** generates a visualization object receptacle disposed along a depth aspect. For example, the system **100**, implementing any one of the UI engines described in FIGS. 2, 5 and 6, can generate a visualization object receptacle disposed along a depth aspect, such as the visualization object receptacle **1114**, as shown in FIG. 12.

Stage **4304** generates one or more visualization objects disposed within the visualization object receptacle. For example, the system **100**, implementing any one of the UI engines described in FIGS. 2, 5 and 6, can generate one or more visualization objects disposed within the visualization object receptacle, such as the visualization objects **1122**, **1124**, **1126**, **1128**, **1130** and **1132**, as shown in FIG. 12.

Stage **4306** preeminently displays the visualization object receptacle. For example, the system **100**, implementing any one of the UI engines described in FIGS. 2, 5 and 6, can preeminently display the visualization object receptacle, such as by displaying the visualization object receptacle near the viewing surface of FIG. 12, or by displaying the visualization object receptacle as described with respect to the visualization object receptacle **714** of FIG. 8.

Stage **4308** generates at least one of the visualization objects as a stack item. For example, the system **100**, implementing any one of the UI engines described in FIGS. 2, 5 and 6, can generate at least one of the visualization objects as a stack item, such as the stack items **1128** and **1130** as shown in FIG. 12.

FIG. 44 is a flow diagram of an example process **4400** for color coding visualization objects. The process **4400** can, for example, be implemented in a processing device, such as the system **100** of FIG. 1, implementing user interface software and/or hardware, such as the example implementations described with respect to FIGS. 2, 5 and 6.

Stage **4402** associates a first color with an executing application. For example, the system **100**, implementing any one of the UI engines described in FIGS. 2, 5 and 6, can associate a first color with an executing application, such as the status indicator **1830**, as shown in FIG. 18D.

Stage **4404** associates a second color with a selected and executing application. For example, the system **100**, implementing any one of the UI engines described in FIGS. 2, 5 and 6, can associate a second color with a selected and executing application, such as the status indicator **1832**, as shown in FIG. 18D.

Stage **4406** associates a third color with a launching of an application. For example, the system **100**, implementing any one of the UI engines described in FIGS. 2, 5 and 6, can associate a third color with a launching of an application, such as the status indicator **1834**, as shown in FIG. 18D.

FIG. 45 is a flow diagram of an example process **4500** for color coding visualization objects of related system objects. The process **4500** can, for example, be implemented in a processing device, such as the system **100** of FIG. 1, implementing user interface software and/or hardware, such as the example implementations described with respect to FIGS. 2, 5 and 6.

Stage **4502** color codes a selected visualization object disposed in the visualization object receptacle. For example, the system **100**, implementing any one of the UI engines described in FIGS. 2, 5 and 6, can color code a selected visualization object disposed in the visualization object receptacle, such as color coding the visualization object **2206**, as shown in FIG. 22.

Stage **4504** applies a corresponding color code to the desktop items associated with the selected visualization object. For example, the system **100**, implementing any one of the UI engines described in FIGS. 2, 5 and 6, can apply a corresponding color code to the desktop items associated with the selected visualization object, such as color coding the stack item **2208**, the folder **2210** and the window **2212**, as shown in FIG. 22.

FIG. 46 is a flow diagram of another example process **4600** for generating a visualization object receptacle. The process **4600** can, for example, be implemented in a processing device, such as the system **100** of FIG. 1, implementing user interface software and/or hardware, such as the example implementations described with respect to FIGS. 2, 5 and 6.

Stage **4602** defines visualization object rows in the visualization object receptacle. For example, the system **100**, implementing any one of the UI engines described in FIGS. 2, 5 and 6, can define visualization object rows in the visualization object receptacle, such as the visualization object rows **2312** and **2314**, as shown in FIG. 23.

Stage **4604** defines visualization object columns in the visualization object receptacle. For example, the system **100**, implementing any one of the UI engines described in FIGS. 2, 5 and 6, can define visualization object columns in the visualization object receptacle, such as the visualization object columns **2322**, **2324**, **2326**, **2328**, **2330**, and **2332**, as shown in FIG. 23.

Stage **4606** disposes the visualization objects within the visualization object receptacle according to the visualization object rows and visualization object columns. For example, the system **100**, implementing any one of the UI engines described in FIGS. 2, 5 and 6, can dispose the visualization objects within the visualization object receptacle according to the visualization object rows and visualization object columns, as indicated by the solid and dashed arrows shown in FIG. 23.

FIG. 47 is a flow diagram of an example process **4700** for generating a stack item. The process **4700** can, for example, be implemented in a processing device, such as the system **100** of FIG. 1, implementing user interface software and/or hardware, such as the example implementations described with respect to FIGS. 2, 5 and 6.

Stage **4702** generates or identifies a plurality of stack elements corresponding to computer system objects. For example, the system **100**, implementing any one of the UI engines described in FIGS. 2, 5 and 6, can generate a plurality of stack elements corresponding to computer system objects, such as the stack elements shown in FIG. 29.

Stage **4704** associates the plurality of stack elements with a stack item. For example, the system **100**, implementing any one of the UI engines described in FIGS. **2**, **5** and **6**, can associate the plurality of stack elements with a stack item, such as the stack item **2900**, as shown in FIG. **29**.

Stage **4706** aggregates the stack elements into the stack item. For example, the system **100**, implementing any one of the UI engines described in FIGS. **2**, **5** and **6**, can aggregate the stack elements into the stack item, such as by overlapping the stack elements to form the stack item in FIG. **29**.

Stage **4708** provides context control of the stack item. For example, the system **100**, implementing any one of the UI engines described in FIGS. **2**, **5** and **6**, can provides context control of the stack item, such as the application context **2910**, as shown in FIG. **29**.

FIG. **48** is a flow diagram of an example process **4800** for displaying stack elements according to modal states. The process **4800** can, for example, be implemented in a processing device, such as the system **100** of FIG. **1**, implementing user interface software and/or hardware, such as the example implementations described with respect to FIGS. **2**, **5** and **6**.

Stage **4802** displays the stack elements in a substantial overlapping arrangement in a first modal state. For example, the system **100**, implementing any one of the UI engines described in FIGS. **2**, **5** and **6**, can display the stack elements in a substantial overlapping arrangement in a first modal state, such as the overlapping arrangement of the stack items in the stack element **3000** in the first modal state, as shown in FIG. **30**.

Stage **4804** displays the stack elements in a browsing arrangement in the second modal state. For example, the system **100**, implementing any one of the UI engines described in FIGS. **2**, **5** and **6**, can display the stack elements in a browsing arrangement in the second modal state, such as the fanning arrangement defined by the first terminus **3020** and the second terminus **3022**, as shown in FIG. **30**.

Stage **4806** enables the selection of a stack element in the second modal state. For example, the system **100**, implementing any one of the UI engines described in FIGS. **2**, **5** and **6**, can enable the selection of a stack element in the second modal state, such as a selection of the preeminently disposed stack element **3002**, as shown in FIG. **30**.

FIG. **49** is a flow diagram of an example process **4900** for selecting interaction models and/or visualization models. The process **4900** can, for example, be implemented in a processing device, such as the system **100** of FIG. **1**, implementing user interface software and/or hardware, such as the example implementations described with respect to FIGS. **2**, **5** and **6**.

Stage **4902** identifies a characteristic of stack elements associated with a stack item. For example, the system **100**, implementing any one of the UI engines described in FIGS. **2**, **5** and **6**, can identify a quantity of stack elements associated with the stack item, such as the quantity of stack elements **3002**, **3004**, **3006**, **3008** and **3010**, as shown in FIG. **30**, or a type associated with the stack item.

Stage **4904** identifies interaction models and/or visualization models. For example, the system **100**, implementing any one of the UI engines described in FIGS. **2**, **5** and **6**, can identify a plurality of visualization models, e.g., browsing arrangements, such as the browsing arrangements described with respect to FIGS. **30** and **31**, or interaction models, such as the interaction models described with respect to FIGS. **33A** and **33B**.

Stage **4906** selects an interaction model and/or visualization model based on the characteristic of the stack elements (e.g., the quantity of stack elements, or the type of the stack elements). For example, the system **100**, implementing any

one of the UI engines described in FIGS. **2**, **5** and **6**, can select one of a plurality of browsing arrangements, such as selection the fanning arrangement, as shown in FIG. **30**, or select one of a plurality of interaction modes, as described with respect to FIGS. **33A** and **33B**.

FIG. **50** is a flow diagram of another example process **5000** for generating a stack item. The process **5000** can, for example, be implemented in a processing device, such as the system **100** of FIG. **1**, implementing user interface software and/or hardware, such as the example implementations described with respect to FIGS. **2**, **5** and **6**.

Stage **5002** defines the date ranges for a temporal context. For example, the system **100**, implementing any one of the UI engines described in FIGS. **2**, **5** and **6**, can define the date ranges for a temporal context, such as the date ranges described with respect to FIGS. **28A** and **28B**.

Stage **5004** associates the corresponding stack items with each date range. For example, the system **100**, implementing any one of the UI engines described in FIGS. **2**, **5** and **6**, can associate the corresponding stack items with each date range, such as the stack items **2802**, **2804** and **2806** in FIGS. **28A** and **28B**.

Stage **5006** determines for each stack element a date associated with each associated system object. For example, the system **100**, implementing any one of the UI engines described in FIGS. **2**, **5** and **6**, can determine for each stack element a date associated with each associated system object, such as a file modification date, as described with respect to FIGS. **28A** and **28B**.

Stage **5008** associates the stack elements with the stack items based on the date ranges associated with the stack items and the dates associated with each system object. For example, the system **100**, implementing any one of the UI engines described in FIGS. **2**, **5** and **6**, can associate the stack elements with the stack items based on the date ranges associated with the stack items and the dates associated with each system object, such as the stack elements associated with the stack items **2802**, **2804** and **2806**, as shown in FIG. **28**.

FIG. **51** is a flow diagram of an example process **5100** for displaying a stack item according to an execution context. The process **5100** can, for example, be implemented in a processing device, such as the system **100** of FIG. **1**, implementing user interface software and/or hardware, such as the example implementations described with respect to FIGS. **2**, **5** and **6**.

Stage **5102** associates a stack item with an application system object. For example, the system **100**, implementing any one of the UI engines described in FIGS. **2**, **5** and **6**, can associate a stack item with an application system object, such as the association of the stack item **2900** with an application, as shown in FIG. **29**.

Stage **5104** associates stack elements associated with the application system object with the stack item associated with the application system object. For example, the system **100**, implementing any one of the UI engines described in FIGS. **2**, **5** and **6**, can associate stack elements associated with the application system object with the stack item associated with the application system object, such as the stack elements of the stack item **2900**, as shown in FIG. **29**.

Stage **5106** displays the stack item associated with the application system object during an executing context. For example, the system **100**, implementing any one of the UI engines described in FIGS. **2**, **5** and **6**, can display the stack item associated with the application system object during an executing context, such as the displaying of the stack item **2900** during an executing and selected state **2912**, as shown in FIG. **29**.

## 35

FIG. 52 is a flow diagram of an example process 5200 for generating and displaying a stack item. The process 5200 can, for example, be implemented in a processing device, such as the system 100 of FIG. 1, implementing user interface software and/or hardware, such as the example implementations described with respect to FIGS. 2, 5 and 6.

Stage 5202 associates a plurality of stack elements with an application. For example, the system 100, implementing any one of the UI engines described in FIGS. 2, 5 and 6, can associate a plurality of stack elements with an application, such as the stack element 2600 with an application, as shown in FIGS. 26 and 27.

Stage 5204 identifies stack file elements and stack application elements. For example, the system 100, implementing any one of the UI engines described in FIGS. 2, 5 and 6, can identify stack file elements and stack application elements, such as the file elements 2604, 2606, 2608 and 2610 and the application element 2602, as shown in FIGS. 26 and 27.

Stage 5206 associates a stack item with the plurality of stack items. For example, the system 100, implementing any one of the UI engines described in FIGS. 2, 5 and 6, can associate a stack item with the plurality of stack elements, such as the stack time 2600 with the stack elements 2602, 2604, 2606, 2608 and 2610, as shown in FIGS. 26 and 27.

Stage 5208 aggregates stack elements to generate stack items. For example, the system 100, implementing any one of the UI engines described in FIGS. 2, 5 and 6, can aggregate stack elements to generate stack items, such as the aggregation shown in FIG. 26 or 27.

Stage 5210 preeminently disposes the application element. For example, the system 100, implementing any one of the UI engines described in FIGS. 2, 5 and 6, can preeminently dispose the application element, such as the preeminently disposed stack element 2602, as shown in FIG. 26 or 27.

FIG. 53 is a flow diagram of an example process 5300 for automatically selecting and applying an interaction model to a stack item. The process 5300 can, for example, be implemented in a processing device, such as the system 100 of FIG. 1, implementing user interface software and/or hardware, such as the example implementations described with respect to FIGS. 2, 5 and 6.

Stage 5302 associates visualizations of system objects. For example, the system 100, implementing any one of the UI engines described in FIGS. 2, 5 and 6, can associate the visualizations of system objects, such as the visualizations corresponding to the stack elements 3002, 3004, 3006, 3008 and 3010, as shown in FIG. 30.

Stage 5304 identifies one or more association characteristics of the associated visualizations. For example, the system 100, implementing any one of the UI engines described in FIGS. 2, 5 and 6, can identify one or more association characteristics of the associated visualizations, such as the number of stack elements shown in FIG. 30.

Stage 5306 automatically selects an interaction model from a plurality of interaction models based on the identified one or more associated characteristics. For example, the system 100, implementing any one of the UI engines described in FIGS. 2, 5 and 6, can automatically select an interaction model from a plurality of interaction models based on the identified one or more associated characteristics, such as selecting one of the interaction models shown in FIGS. 30 and 31.

Stage 5308 applies the selected interaction model to the associated visualizations. For example, the system 100, implementing any one of the UI engines described in FIGS. 2,

## 36

5 and 6, can apply the selected interaction model to the associated visualizations, such as the fanning arrangement as shown in FIG. 30.

FIG. 54 is a flow diagram of another example process 5400 for automatically selecting and applying an interaction model to a stack item. The process 5400 can, for example, be implemented in a processing device, such as the system 100 of FIG. 1, implementing user interface software and/or hardware, such as the example implementations described with respect to FIGS. 2, 5 and 6.

Stage 5402 identifies a quantity of visualizations in the stack association. For example, the system 100, implementing any one of the UI engines described in FIGS. 2, 5 and 6, can identify a quantity of visualizations in the stack association, such as the quantity of stack elements 3102, 3104, 3106 and 3108, as shown in FIG. 31A.

Stage 5404 selects the interaction model from the plurality of interaction models based on the quantity. For example, the system 100, implementing any one of the UI engines described in FIGS. 2, 5 and 6, can select the interaction model from the plurality of interaction models based on the quantity, such as the interaction model shown in FIG. 31A.

FIG. 55 is a flow diagram of another example process 5500 for automatically selecting and applying an interaction model to a stack item. The process 5500 can, for example, be implemented in a processing device, such as the system 100 of FIG. 1, implementing user interface software and/or hardware, such as the example implementations described with respect to FIGS. 2, 5 and 6.

Stage 5502 identifies a type of stack element in the stack association. For example, the system 100, implementing any one of the UI engines described in FIGS. 2, 5 and 6, can identify a type of stack element in the stack association, such as, for example, a document type.

Stage 5504 selects the interaction model from the plurality of interaction models based on the type. For example, the system 100, implementing any one of the UI engines described in FIGS. 2, 5 and 6, can select the interaction model from the plurality of interaction models based on the type, such as, for example, an interaction model designed for the document type.

FIG. 56 is a flow diagram of another example process 5600 for automatically selecting and applying an interaction model to a stack item. The process 5600 can, for example, be implemented in a processing device, such as the system 100 of FIG. 1, implementing user interface software and/or hardware, such as the example implementations described with respect to FIGS. 2, 5 and 6.

Stage 5602 identifies a group association of stack elements in the stack association. For example, the system 100, implementing any one of the UI engines described in FIGS. 2, 5 and 6, can identify a group association of stack elements in the stack association, such as the project association of FIG. 33A.

Stage 5604 selects the interaction model from the plurality of interaction models based on the group association. For example, the system 100, implementing any one of the UI engines described in FIGS. 2, 5 and 6, can select the interaction model from the plurality of interaction models based on the group association, such as a multiple launch interaction model, a synchronization interaction model, or a reconciliation interaction model.

FIG. 57 is a flow diagram of an example process 5700 for generating a divet. The process 5700 can, for example, be implemented in a processing device, such as the system 100 of FIG. 1, implementing user interface software and/or hardware, such as the example implementations described with respect to FIGS. 2, 5 and 6.

37

Stage **5702** generates a visualization object receptacle disposed along a depth aspect. For example, the system **100**, implementing any one of the UI engines described in FIGS. **2**, **5** and **6**, can generate the visualization object receptacle **1802** of FIG. **19A**.

Stage **5704** generates one or more visualization objects disposed within the visualization object receptacle. For example, the system **100**, implementing any one of the UI engines described in FIGS. **2**, **5** and **6**, can generate the one or more visualization objects **1804**, **1806**, **1808**, **1810**, **1812** and **1814** of FIG. **19A**.

Stage **5706** identifies an actionable state associated with one of the visualization objects. For example, the system **100**, implementing any one of the UI engines described in FIGS. **2**, **5** and **6**, can identify an actionable state, e.g., a system update availability, associated with the visualization object **1804** of FIG. **19A**.

Stage **5708** generates a divet displayed proximate to the visualization object to indicate an actionable state associated with the visualization object. For example, the system **100**, implementing any one of the UI engines described in FIGS. **2**, **5** and **6**, can generate the divet **1902** of FIG. **19A**.

FIG. **58** is a flow diagram of an example process **5800** for generating a divet contextual menu. The process **5800** can, for example, be implemented in a processing device, such as the system **100** of FIG. **1**, implementing user interface software and/or hardware, such as the example implementations described with respect to FIGS. **2**, **5** and **6**.

Stage **5802** receives a selection of the divet. For example, the system **100**, implementing any one of the UI engines described in FIGS. **2**, **5** and **6**, can receive a selection, e.g., a mouse click, of the divet **1902** of FIG. **19A**.

Stage **5804** generates a contextual menu proximate to the visualization object in response to receiving the selection divet. For example, the system **100**, implementing any one of the UI engines described in FIGS. **2**, **5** and **6**, can generate the contextual menu **1910** of FIG. **19B**.

The apparatus, methods, flow diagrams, and structure block diagrams described in this patent document may be implemented in computer processing systems including program code comprising program instructions that are executable by the computer processing system. Other implementations may also be used. Additionally, the flow diagrams and structure block diagrams described in this patent document, which describe particular methods and/or corresponding acts in support of steps and corresponding functions in support of disclosed structural means, may also be utilized to implement corresponding software structures and algorithms, and equivalents thereof.

This written description sets forth the best mode of the invention and provides examples to describe the invention and to enable a person of ordinary skill in the art to make and use the invention. This written description does not limit the invention to the precise terms set forth. Thus, while the invention has been described in detail with reference to the examples set forth above, those of ordinary skill in the art may effect alterations, modifications and variations to the examples without departing from the scope of the invention.

What is claimed is:

**1.** A non-transitory computer readable medium storing instructions that are executable by a processing device for causing the processing device to perform operations comprising:

providing for display in a graphical user interface a first stack element corresponding to a first data item, the first

38

stack element having a first display aspect ratio, the first display aspect ratio being determined based on an aspect ratio of the first data item;

providing for display in the graphical user interface a second stack element corresponding to a second data item, wherein the second stack element comprises an indicium having a second display aspect ratio that is different from the first display aspect ratio, where the second display aspect ratio is determined based on an aspect ratio of the second data item;

normalizing the second stack element by adding one or more borders to surround the indicium, wherein corresponding areas of the added borders are determined such that the normalized second stack element has the first display aspect ratio, where the second display aspect ratio of the indicium is preserved; and

providing for display in the graphical user interface a stack item, the stack item including the first stack element and the normalized second stack element.

**2.** The computer readable medium of claim **1**, the operations further comprising providing a contextual control of the stack item, wherein:

the context control comprises a plurality of modal states applied to the stack item.

**3.** The computer readable medium of claim **2**, wherein:

the plurality of modal states comprises:

a first modal state in which the first stack element and the normalized second stack element are displayed in a substantial overlapping arrangement; and

a second modal state in which the first stack element and the normalized second stack element are displayed as unitary instances.

**4.** The computer readable medium of claim **3**, wherein: the first and second modal states are toggle states.

**5.** The computer readable medium of claim **3**, wherein:

at least one of the first stack element and the normalized second stack element comprises a window instance.

**6.** The computer readable medium of claim **3**, wherein:

at least one of the first stack element and the normalized second stack element comprises a representation of a peripheral device, wherein the peripheral device includes one or more of hard drives or universal serial bus devices.

**7.** The computer readable medium of claim **2**, wherein:

the plurality of modal states comprises:

a first modal state in which the first stack element and the normalized second stack element are displayed in a substantially overlapping arrangement; and

a second modal state in which the first stack element and the normalized second stack element are displayed according to a visualization model.

**8.** The computer readable medium of claim **7**, wherein:

each displayed stack element in the second modal state is selectable.

**9.** The computer readable medium of claim **8**, wherein:

the visualization model generates an arrangement of the first stack element and the normalized second stack element in substantial juxtaposition.

**10.** The computer readable medium of claim **8**, wherein:

the visualization model defines a multidimensional path defined by an first terminus and a second terminus; and the visualization model generates a disposition of the first stack element and the normalized second stack element along the multidimensional path.

39

11. The computer readable medium of claim 10, further comprising:

in response to a user input, transitioning the first stack element and the normalized second stack element along the multidimensional path between the first terminus and the second terminus.

12. The computer readable medium of claim 10, further comprising:

providing for display an indicator indicating that one of the first stack element or the normalized second stack element is at a preeminent position when the stack element is located at the first terminus.

13. The computer readable medium of claim 7, wherein: the visualization model is automatically selected based on a quantity of stack elements.

14. The computer readable medium of claim 2, wherein: the context control controls an instantiation of at least one of the stack item and stack elements.

15. The computer readable medium of claim 14, wherein: the instantiation of at least one of the stack item and stack elements is based on a temporal context.

16. The computer readable medium of claim 15, wherein: the temporal context defines date ranges;

a corresponding stack item is associated with each date range; and

a stack element associated with a data item is further associated with a stack item if a relevant date associated with the data item is within the date range associated with the stack item.

17. The computer readable medium of claim 16, wherein: each stack item is color coded according to the date range.

18. The computer readable medium of claim 1, wherein: each stack element corresponds to a desktop menu data item.

19. The computer readable medium of claim 1, wherein: the data items comprise icons;

the graphical user interface comprises an inclusion region associated with the stack item; and

placement of an icon within the inclusion region generates a stack element associated with the icon.

20. The computer readable medium of claim 19, wherein: the inclusion region is coincident with the stack element; and

placement of a stack element without the inclusion region disassociates the stack element with the stack item.

21. The computer readable medium of claim 1, wherein: the graphical user interface comprises:

an under lighting effect to indicate selection of the stack item.

22. A non-transitory computer readable medium storing instructions that are executable by a processing device for causing the processing device to perform operations comprising:

providing for display in a graphical user interface a first stack element corresponding to a first data item, the first stack element having a first display aspect ratio, the first display aspect ratio being determined based on an aspect ratio of the first data item;

identifying an indicium of a second data item, the indicium having a second display aspect ratio that is different from the first display aspect ratio, where the second display aspect ratio is determined based on an aspect ratio of the second data item;

adding one or more borders to surround the indicium to form a normalized stack element, such that the normal-

40

ized stack element has the first display aspect ratio, where the second display aspect ratio of the indicium is preserved;

providing for display in the graphical user interface a stack item, the stack item including the first stack element and the normalized stack element; and

providing a contextual control of the stack item,

wherein the contextual control comprises a plurality of modal states applied to the stack item and controls an instantiation of at least one of the stack item and stack elements,

wherein the instantiation of at least one of the stack item and stack elements is based on an application context,

wherein the application context defines an executing context and a non-executing context, wherein:

a corresponding stack item is associated with an application system object,

corresponding stack elements associated with the stack item are associated with application file system objects associated with the application system object, the corresponding stack item is displayed during the executing context, and

the corresponding stack item is suppressed during the non-executing context.

23. A computer-implemented method, comprising:

providing for display in a graphical user interface a first stack element corresponding to a first data item, the first stack element having a first display aspect ratio, the first display aspect ratio being determined based on an aspect ratio of the first data item;

providing for display in the graphical user interface a second stack element corresponding to a second data item, wherein the second stack element comprises an indicium having a second display aspect ratio that is different from the first display aspect ratio, the second display aspect ratio being determined based on an aspect ratio of the second data item;

normalizing the second stack element by adding one or more borders to surround the indicium, wherein corresponding areas of the added borders are determined such that the normalized second stack element has the first display aspect ratio, where the second display aspect ratio of the indicium is preserved; and

aggregating the first stack element and the normalized second stack element into a stack item; and

providing the stack item for display.

24. The method of claim 23, further comprising providing a contextual control of the stack item, wherein:

providing context control of the stack item comprises providing context control of the stack item based on a plurality of modal states.

25. The method of claim 24, comprising:

providing the first stack element and the normalized second stack element for display in a substantial overlapping arrangement in a first modal state; and providing the stack element and the normalized second stack element for display as unitary instances in a second modal state.

26. The method of claim 25, wherein:

the first and second modal states are toggle states; and the first stack element and the normalized second stack element comprise window instances.

27. The method of claim 24, comprising:

providing the first stack element and the normalized second stack element for display in a substantial overlapping arrangement in a first modal state;

## 41

providing the first stack element and the normalized second stack element for display in a browsing arrangement in a second modal state; and  
 enabling selection of a stack element in the second modal state. 5

**28.** The method of claim **27**, comprising:  
 receiving a selection for a stack element in the second modal state; and  
 generating an instruction to launch an application associated with the selected stack element in response to the selection. 10

**29.** The method of claim **23**, comprising:  
 identifying a quantity of stack elements associated with the stack item; 15  
 identifying a plurality of browsing arrangements; and  
 selecting a browsing arrangement based on the quantity of stack elements.

**30.** The method of claim **27**, wherein:  
 providing the first stack element and the normalized second stack element for display in a browsing arrangement comprises: 20  
 defining a multi-dimensional path; and  
 disposing at least a subset of the stack elements along the multi dimensional path. 25

**31.** The method of claim **26**, comprising:  
 identifying system object data; and  
 displaying the indicium for each stack element based on the system object data, the indicium being unique for the each stack element. 30

**32.** The method of claim **24**, wherein:  
 providing context control of the stack item comprises:  
 controlling instantiation of at least one of the stack item and stack elements based on a temporal context. 35

**33.** The method of claim **32**, comprising:  
 defining date ranges for the temporal context;  
 associating corresponding stack items with each date range;  
 for each stack element, determining a date associated with each associated system object; and 40  
 associating the stack elements with the stack items based on the date ranges associated with the stack items and the dates associated with each system object.

**34.** The method of claim **33**, comprising: 45  
 color coding each stack item according to a corresponding date range.

**35.** The method of claim **24**, wherein:  
 providing context control of the stack item comprises:  
 controlling an instantiation of at least one of the stack item and stack elements based on an application context. 50

**36.** The method of claim **23**, comprising:  
 associating the stack item with an application system object; 55  
 further associating stack elements associated with the application system object with the stack item associated with the application system object; and  
 displaying the stack item associated with the application system object during an executing context. 60

**37.** The method of claim **23**, wherein:  
 each stack element corresponds to a desktop menu system object.

**38.** The method of claim **23**, comprising: 65  
 generating an under lighting selection indicator to indicate a selected stack item.

## 42

**39.** The method of claim **23**, wherein:  
 providing context control of the stack item comprises:  
 controlling the stack item based on an automatic selection of a visualization model from a plurality of visualization models.

**40.** The method of claim **39**, comprising:  
 identifying a quantity of stack elements associated with the stack item; and  
 selecting the visualization model from the plurality of visualization models based on the quantity.

**41.** The method of claim **39**, comprising:  
 identifying a type of stack elements associated with the stack item; and  
 selecting an interaction model from a plurality of interaction models based on the type.

**42.** The method of claim **23**, comprising:  
 applying a group association to the stack item, wherein providing context control of the stack item comprises:  
 controlling the stack item based on an automatic selection of an interaction model based on the group association.

**43.** A system comprising:  
 one or more hardware processors; and  
 memory encoding instructions that, when executed by the one or more hardware processors cause the system to perform operations comprising:  
 providing a graphical user interface;  
 providing for display a first stack element corresponding to a first data item, the first stack element having a first display aspect ratio, the first display aspect ratio, the first display aspect ratio being determined based on an aspect ratio of the first data item;  
 providing for display in the graphical user interface a second stack element corresponding to a second data item, wherein the second stack element comprises an indicium having a second display aspect ratio that is different from the first display aspect ratio, the second display aspect ratio being determined based on an aspect ratio of the second data item;  
 normalizing the second stack element by adding one or more borders to surround the indicium, wherein corresponding areas of the added borders are determined such that the normalized second stack element has the first display aspect ratio, where the second display aspect ratio of the indicium is preserved; and  
 providing for display a stack item, the stack item comprising an aggregation of the first stack element and the normalized second stack element.

**44.** The system of claim **43**, wherein:  
 the aggregation comprises an overlapping display of the first stack and the normalized second stack element.

**45.** The system of claim **44**, wherein:  
 the first data item includes an application element associated with an application executable;  
 the second data item includes a file element associated with an application document file;  
 the aggregation includes a preeminent disposition of a stack element; and  
 the preeminent disposition of the stack element comprises a display of the application element on top of the overlapping display.

**46.** The system of claim **45**, wherein:  
 the preeminent disposition of the stack element comprises an enlargement of the application element relative to the file element.

47. The system of claim 45, wherein:  
the preeminent disposition of the stack element comprises:  
a rendering of the file element as a translucent element;  
and  
a rendering the application element as an opaque ele- 5  
ment.
