(57) **ABSTRACT**

An LED includes a compound semiconductor structure having first and second compound layers and an active layer, first and second electrode layers atop the second compound semiconductor layer and connected to respective compound layers. An insulating layer is coated in regions other than where the first and second electrode layers are located. A conducting adhesive layer is formed atop the non-conductive substrate, connecting the same to the first electrode layer and insulating layer. Formed on one side surface of the non-conductive substrate and adhesive layer is a first electrode connection layer connected to the conducting adhesive layer. A second electrode connection layer formed on another side surface is connected to the second electrode layer. By forming connection layers on respective side surfaces of the light-emitting device, manufacturing costs can be reduced.

LIGHT-EMITTING DEVICE**

CROSS-REFERENCE TO RELATED
APPLICATIONS

This application is a continuation of U.S. patent application Ser. No. 13/253,515, filed Oct. 5, 2011, which claims the benefit of Korean Patent Application No. 10-2010-0113478, filed on Nov. 15, 2010, in the Korean Intellectual Property Office, the disclosures of which are incorporated herein in their entirety by reference.

BACKGROUND

1. Field

The present disclosure relates to light-emitting devices and methods of manufacturing the same.

2. Description of the Related Art

Light-emitting devices, such as light-emitting diodes (LEDs), refer to semiconductor devices that may create various colors of light by constituting a light source through a PN junction of a compound semiconductor. For example, nitride-based LEDs using III-V compound semiconductors such as GaN, InN, and AlN are widely used as light-emitting devices for emitting blue light. Such light-emitting devices have advantages in that they have a long lifespan, are easily made small and light, have a strong directivity of light, and are driven at a low voltage. Also, such light-emitting devices may be applied in various fields because they are strong against impact and vibration, do not need to be preheated, are driven simply, and are packaged in various forms.

There are suggested vertical light-emitting devices which are formed by stacking compound semiconductor layers on an insulating substrate, such as a sapphire substrate that is known to be the most likely substrate satisfying lattice matching conditions for crystal growth, and removing the insulating substrate. Such vertical light-emitting devices are divided into vertical light-emitting devices in which an n-type electrode and a p-type electrode are disposed on the same surface of a compound semiconductor structure and vertical light-emitting devices in which an n-type electrode and a p-type electrode are disposed on different surfaces of a compound semiconductor structure. The vertical light-emitting devices in which the n-type electrode and the p-type electrode are disposed on the same surface of the compound semiconductor structure have advantages in that current spreading is improved and a light passage is prevented from being blocked by the electrodes.

SUMMARY

Provided are light-emitting devices and methods of manufacturing the same which facilitate a manufacturing process and reduce manufacturing cost by forming a connection layer on a side surface of a light-emitting device.

Additional aspects will be set forth in part in the description which follows and, in part, will be apparent from the description, or may be learned by practice of the presented embodiments.

According to an aspect of the present invention, a light-emitting device includes: a compound semiconductor structure which includes a first compound semiconductor layer, an active layer, and a second compound semiconductor layer; a first electrode layer and a second electrode layer which are disposed on a top surface of the second compound semiconductor layer and are respectively electrically connected to the

2

first compound semiconductor layer and the second compound semiconductor layer; an insulating layer which is coated on a portion other than portions where the first electrode layer and the second electrode layer are located; a conducting adhesive layer which is formed on a top surface of a non-conductive substrate and connects the non-conductive substrate to the first electrode layer and the insulating layer; a first electrode connection layer which is formed on one side surfaces of the non-conductive substrate and the conducting adhesive layer and is connected to the conducting adhesive layer; and a second electrode connection layer which is formed on the other side surfaces of the non-conductive substrate and the conducting adhesive layer and is connected to the second electrode layer.

According to another aspect of the present invention, a method of manufacturing a light-emitting device includes: forming a compound semiconductor structure by stacking a first compound semiconductor layer, an active layer, and a second compound semiconductor layer on a substrate; forming a first electrode layer and a second electrode layer, which are respectively electrically connected to the first compound semiconductor layer and the second compound semiconductor layer, on a top surface of the compound semiconductor structure; coating an insulating layer on a portion other than portions where the first electrode layer and the second electrode layer are located; adhering a non-conductive substrate to the insulating layer and the first electrode layer by using a conducting adhesive layer; exposing a portion of the conducting adhesive layer and a portion of a top surface of the second electrode layer; connecting a first electrode connection layer to the conducting adhesive layer; and connecting a second electrode connection layer to the second electrode layer.

BRIEF DESCRIPTION OF THE DRAWINGS

These and/or other aspects will become apparent and more readily appreciated from the following description of the embodiments, taken in conjunction with the accompanying drawings of which:

FIG. 1 is a cross-sectional view of a light-emitting device according to an embodiment of the present invention;

FIG. 2 is a cross-sectional view of a light-emitting device according to another embodiment of the present invention; and

FIGS. 3 through 15 are cross-sectional views for explaining a method of manufacturing the light-emitting device of FIG. 1, according to an embodiment of the present invention.

DETAILED DESCRIPTION

FIG. 1 is a cross-sectional view of a light-emitting device according to an embodiment of the present invention.

Referring to FIG. 1, the light-emitting device includes a compound semiconductor structure **110** and an electrode structure disposed on both side surfaces of the compound semiconductor structure **110**.

The compound semiconductor structure **110** includes a first compound semiconductor layer **111**, an active layer **112**, and a second compound semiconductor layer **113** which are grown on a predetermined substrate **100** (see FIG. 4). The substrate **100** may be removed as will be described below (see FIG. 12).

The compound semiconductor structure **110** may be a nitride semiconductor diode which is formed by growing III-V compound semiconductors such as GaN, InN, and AlN. Such nitride semiconductors may be formed by using an insulating substrate such as a sapphire substrate that is known

to be the most likely substrate satisfying lattice matching conditions for crystal growth. The first compound semiconductor layer **111** may have n-type conductivity, and the second compound semiconductor layer **113** may have p-type conductivity. If needed, the first compound semiconductor layer **111** may have p-type conductivity, and the second compound semiconductor layer **113** may have n-type conductivity. The active layer **112** is disposed between the first compound semiconductor layer **111** and the second compound semiconductor layer **113**. The active layer **112** may have, for example, a multi-quantum well structure. The multi-quantum well structure may include a plurality of quantum well layers and a plurality of quantum barrier layers formed between the quantum well layers. In detail, if the compound semiconductor structure **110** is a gallium nitride-based light-emitting diode, the first compound semiconductor layer **111** may be formed of GaN doped with a n-type impurity, the second compound semiconductor layer **113** may be formed of GaN doped with a p-type impurity, and the active layer **112** may be formed by stacking a plurality of quantum well layers formed of InGaN and a plurality of quantum barrier layers formed of GaN. Electrons and holes injected through the first compound semiconductor layer **111** and the second compound semiconductor layer **113** combine with each other in the active layer **112** to emit light L.

The electrode structure includes a first electrode layer **130** and a second electrode layer **140** disposed on the second compound semiconductor **113**, and a first electrode connection layer **181** and a second electrode connection layer **182** respectively electrically connected to the first electrode layer **130** and the second electrode layer **140**.

The first electrode layer **130** is electrically connected to the first compound semiconductor layer **111** through a via-hole **110a** (see FIG. 4) extending from the second compound semiconductor layer **113** to the first compound semiconductor layer **111**. The via-hole **110a** may be formed to have a mesa structure or a vertical structure by using etching. One or more via-holes **110a** may be formed.

The second electrode layer **140** is disposed on the second compound semiconductor layer **113** and is electrically connected to the second compound semiconductor layer **113**. The second electrode layer **140** may be disposed on a portion of the second compound semiconductor layer **113** where the via-hole **110a** is not formed.

The insulating layer **120** is coated on a portion of the compound semiconductor structure **110** other than portions where the second electrode layer **140** and the first electrode layer **130** are formed. The first electrode layer **130** is insulated from the active layer **112**, the second compound semiconductor layer **113**, and the second electrode layer **140** due to the insulating layer **120**.

A conducting adhesive layer **150** is coated on a top surface of a non-conductive substrate **160**, and the non-conductive substrate **160** is adhered to bottom surfaces of the first electrode layer **130** and the insulating layer **120** by applying a predetermined heat and pressure.

A portion of a top surface of the conducting adhesive layer **150** and a portion of a top surface of the second electrode layer **140** are exposed to the outside. The first electrode connection layer **181** and the second electrode connection layer **182** are disposed on both side surfaces of the non-conductive substrate **160** and the conducting adhesive layer **150**. The first electrode connection layer **181** contacts one of the side surfaces of the conducting adhesive layer **150** and the non-conductive substrate **160**, and one end of the first electrode connection layer **181** contacts the exposed portion of the top surface of the conducting adhesive layer **150**. The second

electrode connection layer **182** is disposed to surround the other side surfaces of the conducting adhesive layer **150** and the non-conductive substrate **160**, and one end of the second electrode connection layer **182** contacts the exposed portion of the top surface of the second electrode layer **140**.

The first electrode connection layer **181** and the second electrode connection layer **182** may be formed by depositing a metal, and the metal may be deposited by using E-beam, sputtering, or plating.

In this case, if both the first electrode connection layer **181** and the second electrode connection layer **182** contact the conducting adhesive layer **150**, the first electrode connection layer **181** and the second electrode connection layer **182** are connected and short-circuited. In order to prevent this, an insulating film **170** is disposed between the second electrode connection layer **182**, and the non-conductive substrate **160** and the conducting adhesive layer **150**. Since the insulating film **170** is disposed to directly contact the side surfaces of the non-conductive substrate **160**, the conducting adhesive layer **150**, and the second electrode layer **140**, the second electrode connection layer **182** is prevented from contacting the non-conductive substrate **160** and the conducting adhesive layer **150**. The insulating film **170** may be formed of SiO_x or SixNy, or polymer, polyimide, or epoxy-based material.

Accordingly, the first electrode connection layer **181** is electrically connected to the first electrode layer **130** through the conducting adhesive layer **150**, the second electrode connection layer **182** is electrically connected to the second electrode layer **140**, and the first electrode connection layer **181** and the second electrode connection layer **182** are not short-circuited due to the insulating film **170**.

A package **200** is adhered to a bottom surface of the non-conductive substrate **160** using a conductive adhesive layer **183**. In this case, the first electrode connection layer **181** and the second electrode connection layer **182** are electrically connected to the conductive adhesive layer **183** by contacting the conductive adhesive layer **183**. A via-hole **210** is formed in the package **200** and the conductive adhesive layer **183** to reach the non-conductive substrate **160**. Accordingly, the first electrode connection layer **181** and the second electrode connection layer **182** are not short-circuited due to the via-hole **210**. A protective layer **190** is formed to surround the compound semiconductor structure **110**.

FIG. 2 is a cross-sectional view of a light-emitting device according to another embodiment of the present invention.

Referring to FIG. 2, the light-emitting device is basically identical to the light-emitting device of FIG. 1 in configuration. However, a protective layer **290** is formed to surround not only the compound semiconductor structure **110** but also portions of the first electrode connection layer **181**, the second electrode connection layer **182**, and the conductive adhesive layer **183** which are exposed. The protective layers **190** and **290** for protecting the compound semiconductor structure **110** and so on from the external environment may be formed of a transparent material through which light is transmitted so as not to disturb light extraction.

In the above configurations, since it is difficult and costly to form a via-hole in the non-conductive substrate **160**, the via-hole may not be formed in the non-conductive substrate **160** as shown in the embodiments. A manufacturing process may be facilitated and manufacturing cost may be reduced by forming an electrode on a side surface of the non-conductive substrate **160**.

FIGS. 3 through 15 are cross-sectional views for explaining a method of manufacturing the light-emitting device of FIG. 1, according to an embodiment of the present invention.

5

Although one light-emitting device is manufactured for convenience of explanation in FIGS. 3 through 15, a plurality of light-emitting devices may be actually integrally formed on a wafer and then may be cut into individual light-emitting devices.

Referring to FIG. 3, the compound semiconductor structure 110 is formed by sequentially growing the first compound semiconductor layer 111, the active layer 112, and the second compound semiconductor layer 113 on a top surface of the substrate 100.

The substrate 100 may be one suitable for a compound semiconductor to be grown by using crystal growth. For example, if a nitride semiconductor single crystal is to be grown, the substrate 100 may be selected from a sapphire substrate, a zinc oxide (ZnO) substrate, a gallium nitride (GaN) substrate, a silicon carbide (SiC) substrate, and an aluminum nitride (AlN) substrate. Although not shown in FIG. 2, a buffer layer (not shown) may be formed between the substrate 100 and the first compound semiconductor layer 111. The buffer layer, which is a layer for improving lattice matching with the substrate 100 before growing the first compound semiconductor layer 111, may be generally formed of AlN/GaN.

The compound semiconductor structure 110 may be formed by growing III-V compound semiconductors such as GaN, InN, or AlN by using crystal growth. For example, if the compound semiconductor structure 110 is a gallium nitride-based light-emitting diode, the first compound semiconductor layer 111, the active layer 112, and the second compound semiconductor layer 113 may be each formed of a semiconductor material having a formula represented as $\text{Al}_x\text{In}_y\text{Ga}(1-x-y)\text{N}$ (where $0 \leq x \leq 1$, $0 \leq y \leq 1$, $0 \leq x+y \leq 1$), and may be formed by using epitaxial growth using metal organic chemical vapor deposition (MOCVD) equipment. That is, the first compound semiconductor layer 111 may be formed as a GaN or GaN/AlGaIn layer doped with a first conductive impurity such as silicon (Si), germanium (Ge), or tin (Sn). The active layer 112 may be formed as an InGaIn/GaN layer having a multi-quantum well structure, or one quantum well layer or a double hetero structure. The second compound semiconductor layer 113 may be formed as a GaN or GaN/AlGaIn layer doped with a second conductive impurity such as magnesium (Mg), zinc (Zn), or beryllium (Be).

Next, referring to FIG. 4, a portion of the compound semiconductor structure 110 where the first electrode layer 130 (see FIG. 1) is to be formed is etched to a predetermined depth from the second compound semiconductor layer 113 to form the via-hole 110a and expose a portion of the first compound semiconductor layer 111. The via-hole 110a may be formed to have a mesa structure or a vertical structure. A plurality of the via-holes 110a may be formed to correspond to a plurality of the first electrode layers 130. Next, a passivation layer 121 is coated by using a well-known deposition method on an entire top surface of the compound semiconductor structure 110. For example, the passivation layer 121 may be formed by depositing SiO_2 to a thickness of about 6000 Å by using plasma enhanced chemical vapor deposition (PECVD).

Next, referring to FIG. 5, a portion of the first compound semiconductor layer 111 is exposed by etching a portion of the passivation layer 121 which is formed at the bottom of the via-hole 110a. The etching may be performed by using reactive ion etching (RIE) and a buffered oxide etchant (BOE). Next, the first electrode layer 130 is formed on the exposed portion of the first compound semiconductor layer 111. For example, the first electrode layer 130 may be formed by depositing an Al/Ti/Pt layer to a thickness of 200 nm/1200 nm/20 nm. In this case, current spreading to the first com-

6

pound semiconductor layer 111 may be improved by forming a plurality of the first electrode layers 130.

Referring to FIG. 6, a portion of the second compound semiconductor layer 113 is exposed by etching a portion of the passivation layer 121 other than a portion surrounding the first electrode layer 130. The etching may be performed by using, for example, RIE and a BOE. Next, the second electrode layer 140 is formed on the exposed portion of the second compound semiconductor layer 113. In this case, the second electrode layer 140 is formed to be spaced apart from the first electrode layer 130. The second electrode layer 140 may act as a reflective film formed of a metal having both ohmic characteristics and light reflecting characteristics, or may be formed as layers formed by sequentially stacking metals having ohmic characteristics and light reflecting characteristics. For example, the second electrode layer 140 may be formed by depositing a Ni/Ag/Pt/Ti/Pt layer to a thickness of 0.5 nm/250 nm/50 nm/300 nm/50 nm.

Next, referring to FIG. 7, an insulating material layer 122 is coated to a predetermined thickness on the top surface of the compound semiconductor structure 110. The insulating material layer 122 is coated on a region including the first electrode layer 130, the second electrode layer 140, and the passivation layer 121. The insulating material layer 122 may be formed by, for example, depositing SiO_2 to a thickness of about 8000 Å by using PECVD. The passivation layer 121 and the insulating material layer 122 may be formed of the same material, and constitute the insulating layer 120 with respect to the first electrode layer 130 and the second electrode layer 140.

A portion of the insulating material layer 122 covering a top surface of the first electrode layer 130 is removed, and an Al/Ti/Pt layer for forming the first electrode layer 130 is filled in the removed portion, to integrally form the first electrode layer 130. Then, the first electrode layer 130 is exposed to the outside of the insulating material layer 122. Accordingly, while the first electrode layer 130 is exposed to the outside of the insulating material layer 122, the second electrode layer 140 is blocked from the outside due to the insulating material layer 120.

Referring to FIG. 8, the conducting adhesive layer 150 is coated on a top surface of the non-conductive substrate 160, and then the non-conductive substrate 160 is adhered to the first electrode layer 130 and the insulating layer 120 by applying a predetermined heat and pressure. The non-conductive substrate 160 is adhered to the conducting adhesive layer 150 by applying a heat higher than 300° C. and a predetermined pressure to the first electrode layer 130 and the insulating layer 120. Then, while the first electrode layer 130 contacts the conducting adhesive layer 150, the second electrode layer 140 is separated from the conducting adhesive layer 150 due to the insulating layer 120.

Since a heat higher than 300° C. is applied during adhesion to the non-conductive substrate 160 that acts as a final support layer for the light-emitting device, it is preferable that the non-conductive substrate 160 has a thermal expansion coefficient that is similar to that of the substrate 100.

Referring to FIG. 9, a portion of the conducting adhesive layer 150 is exposed by etching portions of the insulating layer 120, the compound semiconductor structure 110, and the substrate 100 adjacent to the first electrode layer 130. A portion of the second electrode layer 140 is exposed by etching portions of the compound semiconductor structure 110 and the substrate 100 disposed on a top surface of the second electrode layer 140. The etching may be performed by using, for example, RIE and a BOE.

Referring to FIG. 10, the insulating film 170 is formed to a predetermined thickness on side surfaces of the second conductive layer 140, the conducting adhesive layer 150, and the non-conductive substrate 160. Accordingly, the side surfaces of the second electrode layer 140, the conducting adhesive layer 150, and the non-conductive substrate 160 are surrounded by the insulating film 170. The insulating film 170 may be formed SiO_x or Si₃N₄, or polymer, polyimide, or epoxy-based material.

Referring to FIG. 11, the first electrode connection layer 181 is formed to surround the exposed portion of the top surface of the conducting adhesive layer 150 and the side surface of the non-conductive substrate 160. The second electrode connection layer 182 is formed to surround the insulating film 170 and the exposed portion of the top surface of the second electrode layer 140. The first electrode connection layer 181 and the second electrode connection layer 182 may be formed by depositing a metal, such as copper, nickel, or chromium, and the metal may be deposited by using E-beam, sputtering, or plating. In this case, one end of the first electrode connection layer 181 is formed on the top surface of the conducting adhesive layer 150 to be spaced apart by a predetermined interval from the insulating layer 120. One end of the second electrode connection layer 182 is formed on the top surface of the second electrode layer 140 to be spaced apart by a predetermined interval from the second compound semiconductor layer 113. This is to have a space for forming the protective layer 190 (see FIG. 13) that is to be formed to surround the compound semiconductor structure 110.

Next, referring to FIG. 12, the substrate 100 is removed from the compound semiconductor structure 110. Since the top surface of the compound semiconductor structure 110 is a surface for extracting light, the substrate 100 is removed in order to improve light extraction efficiency. Although not shown, a concavo-convex structure may be formed on the top surface of the compound semiconductor structure 110 in order to improve light extraction efficiency.

Referring to FIG. 13, the protective layer 190 is formed to surround the compound semiconductor structure 110. The protective layer 190 for protecting the compound semiconductor structure 110 from the external environment may be formed of a transparent material through which light is transmitted so as not to disturb light extraction.

Referring to FIG. 14, the conductive adhesive layer 183 is coated on a top surface of the package 200, and then the package 200 is adhered to the first electrode connection layer 181, the non-conductive substrate 160, the insulating film 170, and the second electrode connection layer 182. In this case, the first electrode connection layer 181 and the second electrode connection layer 182 are adhered and connected to the conductive adhesive layer 183.

Referring to FIG. 15, a portion of the non-conductive substrate 160 is exposed by forming the via-hole 210 that passes through the package 200 and the conductive adhesive layer 183. In this case, the first electrode connection layer 181 and the second electrode connection layer 182 are not short-circuited due to the via-hole 210. The via-hole 210 may be formed by using various methods such as drilling, ultrasonic milling, laser drilling, sand blasting, or dry etching, or a combination of the methods.

What is claimed is:

1. A method of manufacturing a light-emitting device, the method comprising:

forming a compound semiconductor structure having a first compound semiconductor layer, an active layer, and a second compound semiconductor layer sequentially stacked on a substrate;

forming a via-hole exposing a portion of the first compound semiconductor layer by etching the compound semiconductor structure from the second compound semiconductor layer;

forming a first electrode layer connected to the first compound semiconductor layer within the via-hole;

forming a second electrode layer connected to the second compound semiconductor layer;

forming an insulating layer covering a top surface of the second electrode layer and covering an exposed surface of the compound semiconductor structure surrounding the first electrode layer, a top surface of the first electrode layer being exposed through the insulating layer;

adhering a non-conductive substrate to the insulating layer and to the top surface of the first electrode layer by using a conducting adhesive layer, the conducting adhesive layer continuously extending on a top surface of the non-conductive substrate to cover the entire area of the top surface of the non-conductive substrate;

exposing a first portion of the conducting adhesive layer and a second portion of the second electrode layer by removing portions of the substrate, the compound semiconductor structure, and the insulating layer;

forming a first electrode connection layer connected to the first portion of the conducting adhesive layer; and forming a second electrode connection layer connected to the second portion of the second electrode layer.

2. The method of claim 1, wherein the conducting adhesive layer directly contacts with the top surface of the first electrode layer.

3. The method of claim 1, wherein the forming of the insulating layer comprises:

coating an insulating material layer on the first electrode layer, the second electrode layer, and the exposed surface of the compound semiconductor structure; and removing a portion of the insulating material layer to expose the first electrode layer.

4. The method of claim 1, wherein the forming of the first electrode connection layer comprises forming the first electrode connection layer directly contacting with the first portion of the conducting adhesive layer, a side surface of the conducting adhesive layer, and a side surface of the non-conductive substrate.

5. The method of claim 1, wherein the forming of the first electrode connection layer comprises forming the first electrode connection layer extending from the first portion of the conducting adhesive layer toward the non-conductive substrate.

6. The method of claim 5, wherein the forming of the first electrode connection layer comprises forming the first electrode connection layer extending from the first portion of the conducting adhesive layer to a bottom surface of the non-conductive substrate, the bottom surface of the non-conductive substrate being an opposite side surface to the top surface of the non-conductive substrate.

7. The method of claim 1, wherein the forming of the second electrode connection layer comprises forming the second electrode connection layer directly contacting with the second electrode layer and spaced apart from the conducting adhesive layer.

8. The method of claim 7, wherein the forming of the second electrode connection layer comprises forming the second electrode connection layer extending from the second electrode layer toward the non-conductive substrate.

9

9. The method of claim 7, before the forming of the second electrode connection layer, the method further comprising forming an insulating film on a side surface of the conducting adhesive layer,

wherein the forming of the second electrode connection layer comprises forming the second electrode connection layer on the insulating film, the second electrode connection layer facing with the side surface of the conducting adhesive layer with the insulating film therebetween.

10. The method of claim 7, wherein the forming of the second electrode connection layer comprises forming the second electrode connection layer extending from the second electrode layer to a level at which a bottom surface of the non-conductive substrate extends, the bottom surface of the non-conductive substrate being an opposite side surface to the top surface of the non-conductive substrate.

11. The method of claim 1, wherein the first electrode connection layer is formed to be spaced apart from the insulating layer with a first space therebetween, and

wherein the second electrode connection layer is formed to be spaced apart from the second compound semiconductor layer with a second space therebetween.

12. The method of claim 11, further comprising: removing the substrate to expose a light extracting surface of the compound semiconductor structure; and forming a protection layer surrounding the compound semiconductor structure and filling the first space and the second space.

13. A method of manufacturing a light-emitting device, the method comprising:

forming a compound semiconductor structure by stacking a first compound semiconductor layer, an active layer, and a second compound semiconductor layer on a substrate;

forming a first electrode layer and a second electrode layer, which are respectively electrically connected to the first compound semiconductor layer and the second compound semiconductor layer, on a top surface of the compound semiconductor structure;

coating an insulating layer on the compound semiconductor structure, wherein a first top surface of the first electrode layer is exposed through the insulating layer and a second top surface of the second electrode is covered with the insulating layer;

adhering a non-conductive substrate to the insulating layer and to the first top surface of the first electrode layer by using a conducting adhesive layer, wherein the conduct-

10

ing adhesive layer continuously extends on a top surface of the non-conductive substrate to cover the entire area of the top surface of the non-conductive substrate;

exposing a first portion of the conducting adhesive layer and a second portion of the second electrode layer by removing portions of the substrate, the compound semiconductor structure, and the insulating layer;

forming a first electrode connection layer connected to the first portion of the conducting adhesive layer; and

forming a second electrode connection layer connected to the second portion of the second electrode layer.

14. The method of claim 13, wherein the exposing of the first portion of the conducting adhesive layer and the second portion of the second electrode layer comprises removing portions of both sides of the compound semiconductor structure.

15. The method of claim 13, wherein the forming of the first electrode connection layer comprises forming the first electrode connection layer extending on the first portion and one side surface of the conducting adhesive layer, and on one side surface of the non-conductive substrate.

16. The method of claim 13, before the forming of the second electrode connection layer, the method further comprising forming an insulating film extending on the other side surfaces of the conducting adhesive layer and the non-conductive substrate and on a side surface of the second electrode layer.

17. The method of claim 16, wherein the forming of the second electrode connection layer comprises forming the second electrode connection layer to be connected to the second portion of the second electrode layer while surrounding the insulating film.

18. The method of claim 17, further comprising connecting the non-conductive substrate, the first electrode connection layer, and the second electrode connection layer to a package by using a conductive adhesive layer.

19. The method of claim 18, further comprising electrically separating the first electrode connection layer and the second electrode connection layer from each other by removing portions of the package and the conductive adhesive layer to form a via-hole that passes through the conductive adhesive layer and the package to reach the non-conductive substrate.

20. The method of claim 13, further comprising: removing the substrate to expose a light extracting surface of the compound semiconductor structure; and forming a protective layer surrounding the compound semiconductor structure.
