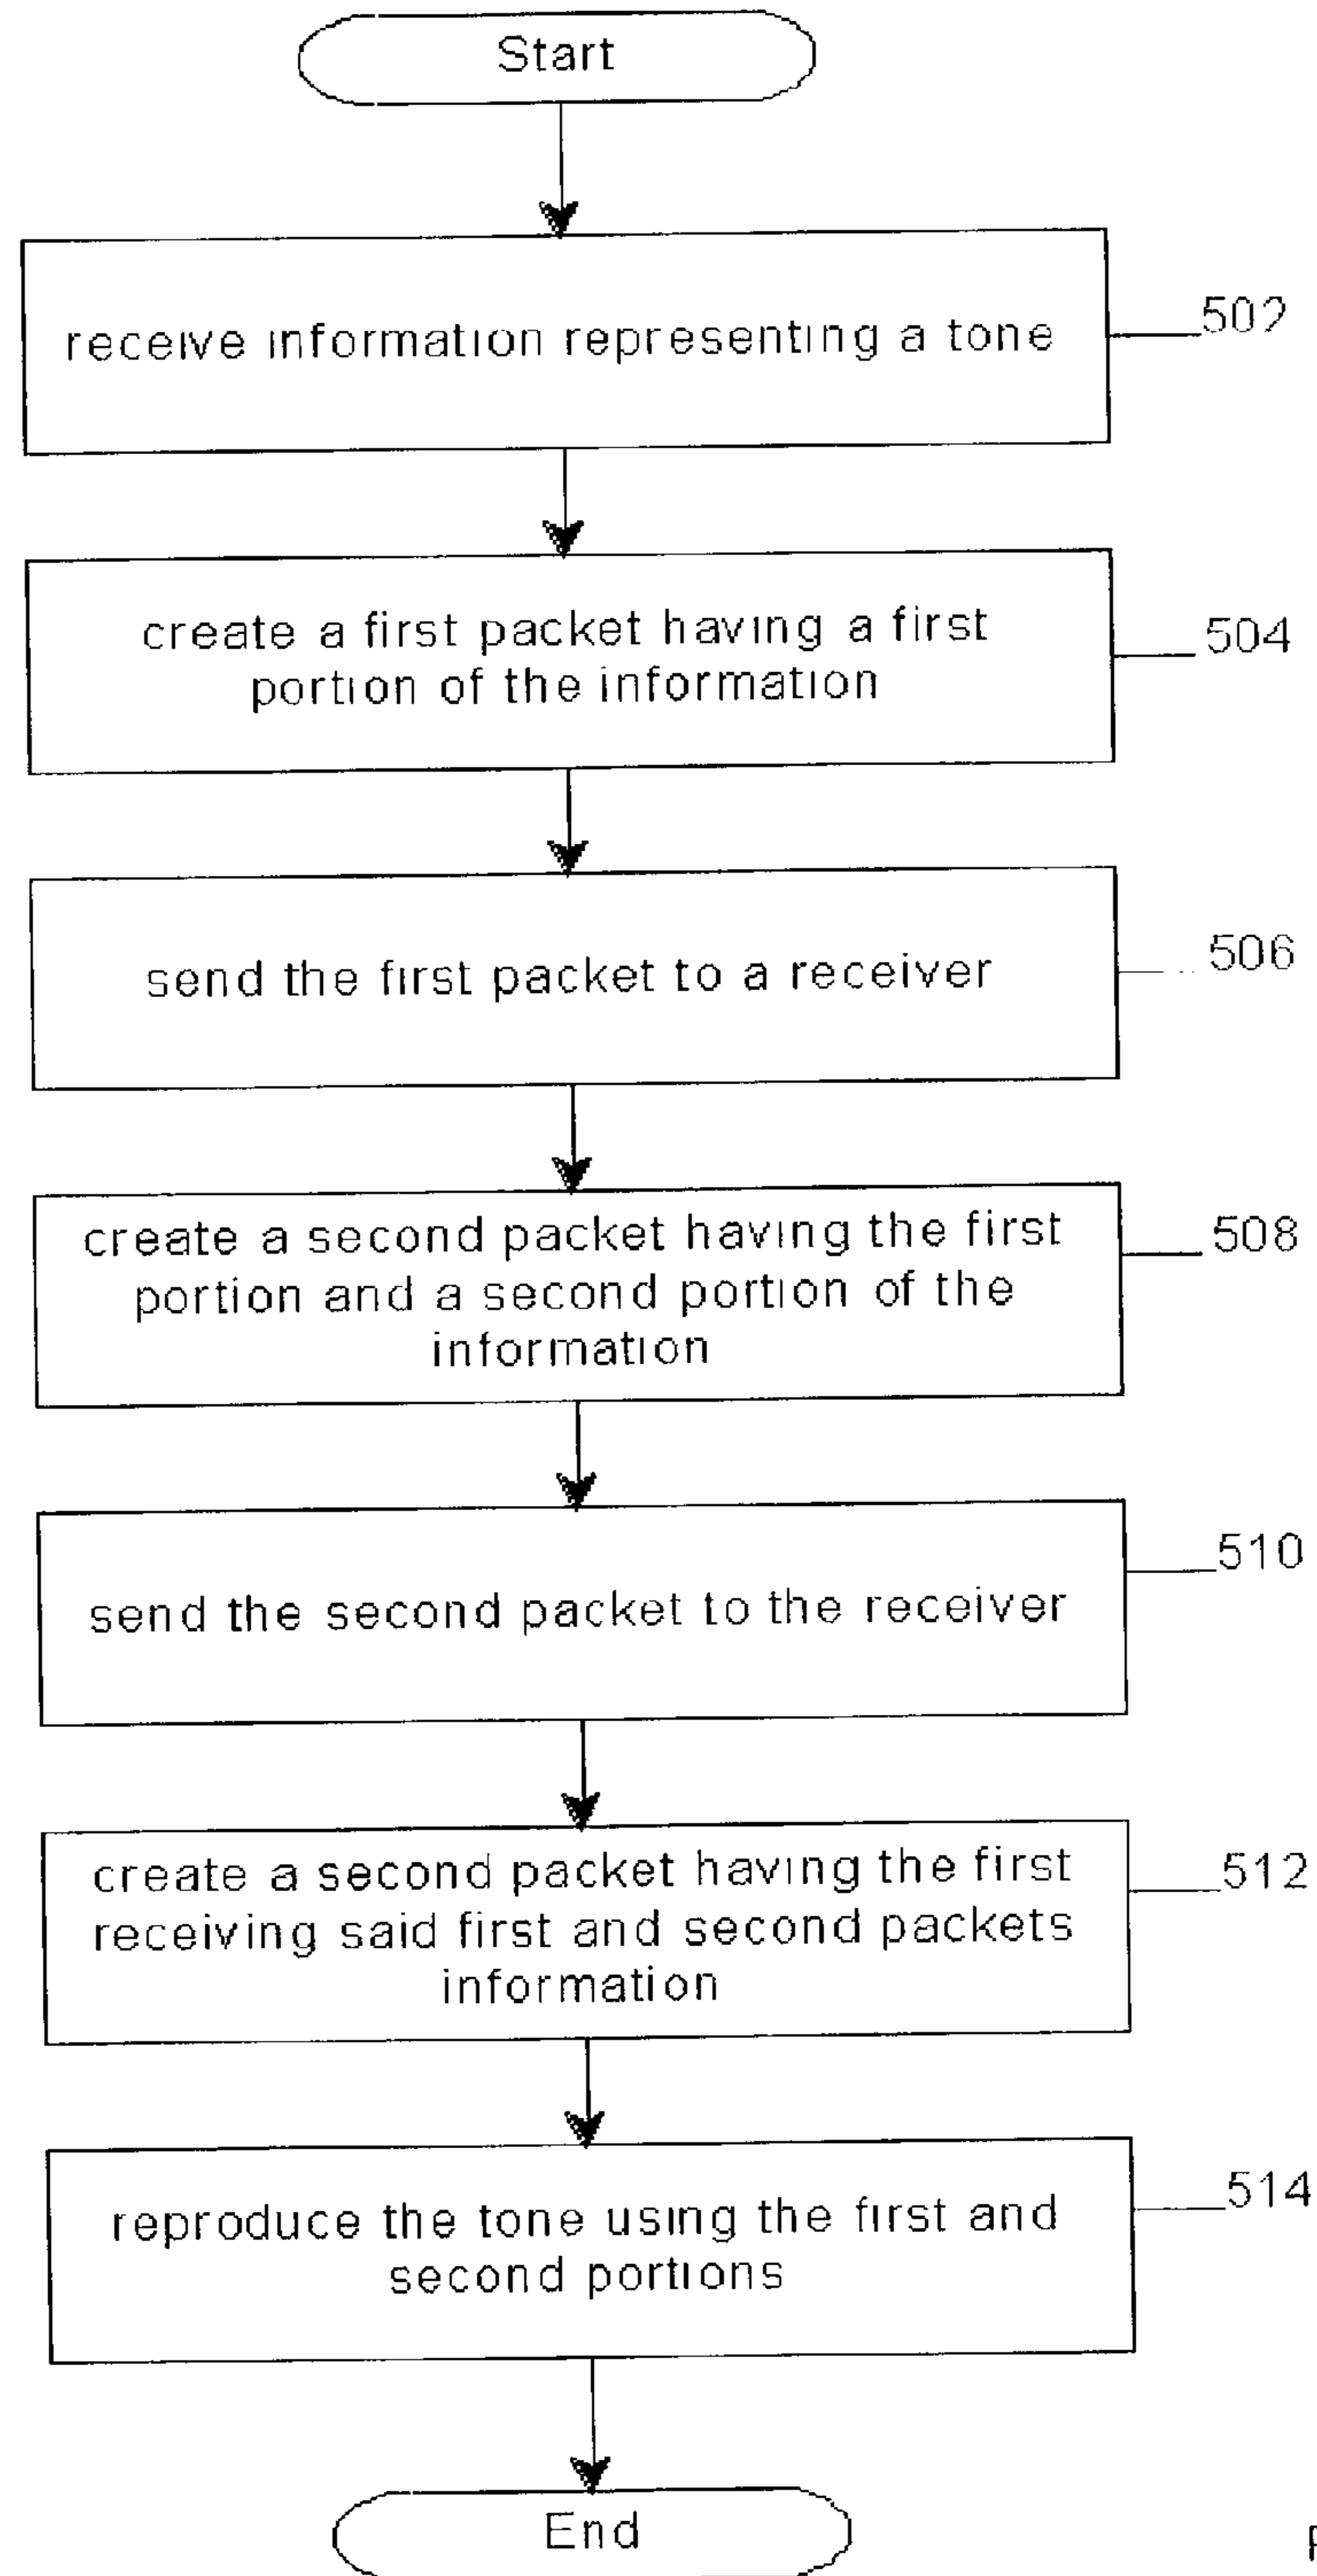

FIG 5

COMMUNICATING TONE INFORMATION IN A NETWORK

RELATED CASE

This application is a Continuation of commonly owned U.S. patent application Ser. No. 10/213,894 titled "Communicating Tone Information in a Network", filed Aug. 6, 2002, now U.S. Pat. No. 8,289,956.

BACKGROUND

Voice over packet (VOP) technology is directed to sending voice signals over a data network. In addition to voice signals, VOP networks must often account for tone signals that may be interleaved with the voice signals. Many systems utilize tone signals to communicate information between the system and a human user, e.g., using Dual Tone Multi-Frequency (DTMF) tones to represent a telephone number. Some systems, however, may need to communicate tone signals using a separate transport mechanism relative to voice signals. Consequently, there may be a need for innovative techniques to process tone signals in a VOP system.

BRIEF DESCRIPTION OF THE DRAWINGS

The subject matter regarded as embodiments of the invention is particularly pointed out and distinctly claimed in the concluding portion of the specification. Embodiments of the invention, however, both as to organization and method of operation, together with objects, features, and advantages thereof, may best be understood by reference to the following detailed description when read with the accompanying drawings in which:

FIG. 1 is a system suitable for practicing one embodiment of the invention.

FIG. 2 illustrates a VOP system suitable for use with one embodiment of the invention.

FIG. 3 (PRIOR ART) illustrates a conventional tone packet created in accordance with the RFC 2833 Specification.

FIG. 4 illustrates a tone packet created in accordance with one embodiment of the invention.

FIG. 5 is a block flow diagram of the operations performed by a TMM in accordance with one embodiment of the invention.

DETAILED DESCRIPTION

Embodiments of the invention may comprise a method and apparatus to communicate tones over a network, such as a VOP network. For example, one embodiment of the invention may be directed to communicating tones in a VOP network in a redundant fashion to mitigate packet loss in the network.

Numerous specific details may be set forth herein to provide a thorough understanding of the embodiments of the invention. It will be understood by those skilled in the art, however, that the embodiments of the invention may be practiced without these specific details. In other instances, well-known methods, procedures, components and circuits have not been described in detail so as not to obscure the embodiments of the invention. It can be appreciated that the specific structural and functional details disclosed herein may be representative and do not necessarily limit the scope of the invention.

It is also worthy to note that any reference in the specification to "one embodiment" or "an embodiment" means that a particular feature, structure, or characteristic described in

connection with the embodiment is included in at least one embodiment of the invention. The appearances of the phrase "in one embodiment" in various places in the specification are not necessarily all referring to the same embodiment.

Referring now in detail to the drawings wherein like parts are designated by like reference numerals throughout, there is illustrated in FIG. 1 a system suitable for practicing one embodiment of the invention. FIG. 1 is a block diagram of a system 100. System 100 may comprise, for example, call terminals 102 and 106 connected by a network 104.

Examples of a call terminal may include any device capable of communicating audio and tone signals over a network. A call terminal may comprise, for example, a conventional telephone set, a wireless telephone, a portable or handheld computer equipped with a transceiver and modem, a personal digital assistant (PDA), a packet telephony telephone and so forth.

Network 106 may comprise, for example, a packet network. In one embodiment of the invention, network 106 may operate in accordance with, for example, one or more Internet protocols such as the Transmission Control Protocol (TCP) as defined by the Internet Engineering Task Force (IETF) standard 7, Request For Comment (RFC) 793, adopted in September, 1981, and the Internet Protocol (IP) as defined by the IETF standard 5, RFC 791, adopted in September, 1981, both available from "www.ietf.org", although the embodiments of the invention are not limited to this context. Network 106 may also operate in accordance with one or more protocols to communicate VOP packets representing audio, voice or tone information. In one embodiment of the invention, for example, network 106 may operate in accordance with the International Telecommunications Union (ITU) Recommendation H.323 titled "Packet-based Multimedia Communication Systems," published in November 2000 and available from "www.itu.int" ("H.323 Specification"); the IETF Proposed Standard RFC 2543 titled "SIP: Session Initiation Protocol," published in March 1999, and available from "www.ietf.org" ("SIP Specification"); or IETF Proposed Standard RFC 2833 titled "RTP Payload for DTMF Digits, Telephony Tones and Telephony Signals," published in May 2000, and available from "www.ietf.org" ("RFC 2833 Specification"). Although specific examples are discussed herein, it may be appreciated that the embodiments of the invention are not limited in this context. Further, network 106 may also include circuit switched technologies and appropriate interfaces to packet network technologies.

FIG. 2 illustrates a VOP system suitable for use with one embodiment of the invention. FIG. 2 is a block diagram of a system 200. System 200 may comprise part of, for example, system 100 shown in FIG. 1. System 200 may comprise a VOP system, including a gateway 202, a gatekeeper 206 and an internal gateway 208. Gateway 202 may also include a Tone Management Module (TMM) 204.

Gateway 202 may operate to convert a conventional telephony call to a packet telephony call or VOP call. Gateway 202 may receive signals from a circuit-switched network, such as the Public Switched Telephone Network (PSTN), and convert the circuit-switched signals into packets. The conversion to packets may be made in accordance with, for example, the TCP/IP Specification, SIP Specification, H.323 Specification and RFC 2833 Specification. Gateway 202 may communicate the packets through other components of system 200 until the packets reach their intended destination, e.g., a call terminal connected to internal gateway 208.

Gatekeeper 206 may perform conventional gatekeeper functions, such as address translation, admission control, call control signaling, call authorization, call management and so

forth in accordance with the SIP Specification or H.323 Specification, for example. In one embodiment of the invention, gatekeeper **206** may provide address and routing information to communicate packets through system **200** to the destination call terminal, such as call terminal **106**.

In one embodiment of the invention, gateway **202** may also include TMM **204**. TMM **204** may manage the communication of tone signals in a network, such as a VOP network. In one embodiment of the invention, TMM **204** may include functionality that may be implemented as software executed by a processor, hardware circuits or structures, or a combination of both. The processor may be a general-purpose or dedicated processor, such as a processor from the family of processors made by Intel Corporation, Motorola Incorporated, Sun Microsystems Incorporated and others. The software may comprise programming logic, instructions or data to implement certain functionality for an embodiment of the invention. The software may be stored in a medium accessible by a machine or computer-readable medium, such as read-only memory (ROM), random-access memory (RAM), magnetic disk (e.g., floppy disk and hard drive), optical disk (e.g., CD-ROM) or any other data storage medium. In one embodiment of the invention, the media may store programming instructions in a compressed and/or encrypted format, as well as instructions that may have to be compiled or installed by an installer before being executed by the processor. Alternatively, an embodiment of the invention may be implemented as specific hardware components that contain hard-wired logic for performing the recited functionality, or by any combination of programmed general-purpose computer components and custom hardware components.

In operation, TMM **204** may detect tone signals received at the gateway, and process the tones in accordance with one or more tone protocols, such as the tone protocol set forth in the RFC 2833 Specification. The RFC 2833 Specification is an Internet standard directed to transporting telephony tones using the Real Time Transport Protocol (RTP). The RFC 2833 Specification outlines that tones sent within an encoded voice stream (“in-band”) tend to become corrupted and unrecognizable at a receiver due to high compression rates. If the tones are sent via traditional TCP/IP, however, significant delays may be incurred due to lost packets or the intrinsically lower priority of conventional TCP/IP traffic. The RFC 2833 Specification attempts to address these problems by defining two types of tone RTP packets communicated in accordance with the User Datagram Protocol (UDP). The transport of tone RTP packets over UDP is unreliable, however, and may still result in losing enough packets to render the receiver incapable of using the tone information.

In an attempt to address this problem, the RFC 2833 Specification describes a redundancy mechanism, where each tone RTP packet not only carries current tone information, but also up to five previous tone events. The term “tone information” as used herein may refer to any information used to represent tone signals, including names, tags, frequency components, time information, and so forth. The term “tone signals” as used herein may refer to any tone signals, such as DTMF tones or other tones used by telephony, VOP or automated systems. The term “tone packets” as used herein may refer to any packet used to carry tone information.

In accordance with the RFC 2833 Specification, the tone packets may include two types of tone information. The first type is tone information representing a current tone event, which may be referred to herein for convenience as “Type One Information.” The second type is tone information representing a previous tone event, which may be referred to herein for convenience as “Type Two Information.” The term

“tone event” as used herein refers to a complete tone signal, e.g., starting time, duration and ending time. In one embodiment of the invention, system **200** may use Type Two Information for redundancy. In the situation where packets carrying a previous tone event are lost, Type Two Information may be used to reconstruct the previous tone event.

Type Two Information, however, may not provide sufficient redundancy in certain cases. For example, a tone event typically lasts longer than the packet or frame size used to transport tone information. Consequently, a VOP system may need to begin transport of Type One Information before the current tone event has been completed. If such packets are corrupted or lost prior to completion of the tone event, the receiver may not have sufficient information to reconstruct the tone event. The redundancy functionality of the Type Two Information would not be useful in this case, since it carries tone information from a previous tone event, and not the current tone event.

In an attempt to solve this and other problems, one embodiment of the invention may utilize a third type of tone information, which may be referred to herein for convenience as “Type Three Information.” Type Three Information may comprise, for example, partial tone information of a current tone event. For example, Type Three Information may be tone information for a current tone event carried by one or more previous packets or frames. In this manner, if one or more packets carrying Type One Information are lost, a receiver may be able to reconstruct the current tone event in a timely manner using the Type Three Information. As stated previously, the redundancy functionality of Type Two Information would not be useful in this case, since it carries tone information from a previous tone event. Type Three Information, however, may be received in sufficient time to be detected and used by the VOP or automated system. This embodiment of the invention may be better illustrated with reference to FIGS. **3** and **4** below.

FIG. **3** (PRIOR ART) illustrates a conventional tone packet created in accordance with the RFC 2833 Specification. FIG. **3** illustrates a typical RTP packet **300**, where the user is just dialing the last digit of the DTMF sequence “911.” The first digit was 200 milliseconds (ms) long (1600 timestamp units) and started at time 0, the second digit lasted 250 ms (2000 timestamp units) and started at time 800 ms (6400 timestamp units), the third digit was pressed at time 1.4 seconds (11,200 timestamp units). Packet **300** illustrates that it was sent at 1.45 seconds (11,600 timestamp units). The frame duration is 50 ms long. It is worthy to note that FIG. **3** ignores byte alignment for purposes of this illustration. Timestamp and sequence number are assumed to have been zero at the beginning of the first digit. As shown in FIG. **3**, RTP tone packet **300** includes Type Two Information for redundancy. For example, elements **302** and **304** indicate the previous tone events for “9” and “1”, respectively. While the Type Two Information may be useful for reconstructing the previous tone events for “9” and “1”, this information would not be helpful to reconstruct the current tone event for the last digit “1” that is still active.

FIG. **4** illustrates a tone packet created in accordance with one embodiment of the invention. FIG. **4** illustrates an RTP packet **400**. Similar to RTP packet **300**, RTP packet **400** indicates three tone events generated by a caller. The three tone events are the DTMF tones “9”, “1” and “1”. The first tone was pressed at time 0 with a duration of 1600 ms. The second tone was pressed at time 6400 ms with a duration of 2000 ms. The third tone was pressed at time 11200 ms, but has not ended. Rather, the third tone event is only 400 ms into the total tone event. Elements **402** and **404** represent tone infor-

5

mation for the previous tone events “9” and “1” for redundancy. In accordance with one embodiment of the invention, however, RTP packet **400** may also include Type Three Information in the form of tone information from two previous tone packets, shown in FIG. **4** as elements **406** and **408**, respectively. These two previous tone frames are the two previous tone frames just prior to the current or most recent tone frame, shown in FIG. **4** as element **410**.

In accordance with one embodiment of the invention, if the tone packets carrying the tone information represented as redundant elements **406** and **408** were lost in transport, the intended receiver may use elements **406** or **408** from RTP tone packet **400** to reconstruct the third tone event of “1” in the “911” sequence.

In one embodiment of the invention, TMM **204** may create a tone packet similar to RTP tone packet **400** described with respect to FIG. **4**. The embodiment may include current tone information, as well as tone information carried by one or more previous packets. In this manner, a receiver may recover tone information in the event one or more packets are lost or corrupted during transmission. This is an improvement over conventional tone management techniques, which are typically based on tone event management rather than tone packet management.

The operations of systems **100** and **200** may be further described with reference to FIG. **5** and accompanying examples. Although FIG. **5** as presented herein may include a particular processing logic, it can be appreciated that the processing logic merely provides an example of how the general functionality described herein can be implemented. Further, each operation within a given processing logic does not necessarily have to be executed in the order presented unless otherwise indicated.

FIG. **5** is a block flow diagram of the operations performed by a TMM in accordance with one embodiment of the invention. In one embodiment of the invention, this or other modules may refer to the software and/or hardware used to implement the functionality for one or more embodiments as described herein. In this embodiment of the invention, this or other modules may be implemented as part of a system, such as system **200**. It can be appreciated that this functionality, however, may be implemented by any device, or combination of devices, located anywhere in a communication network and still fall within the scope of the invention.

FIG. **5** illustrates a programming logic **500** for a TMM in accordance with one embodiment of the invention. As shown in programming logic **500**, tone information may be received at block **502**. In one embodiment of the invention, the tone information may represent DTMF signals, for example. A first packet having a first portion of the tone information may be created at block **504**. The first packet may be sent to a receiver at block **506**. A second packet having the first portion and a second portion of the information may be created at block **508**. The second packet may be sent to the receiver at block **510**. The first and second packets may be received at block **512**. The receiver may reproduce the tone using the first and second portions of tone information at block **514**.

In one embodiment of the invention, the first and second packets may be created in accordance with, for example, the RFC 2833 Specification as modified using the concepts presented herein. More particularly, the packets may be RTP tone packets, with the tone information represented as a name for the tone or a frequency for the tone. In one embodiment of the invention, the frequency and/or duration of the tone may be ascertained and used to search for a corresponding name or event in a table or memory. For example, a tone signal representing a DTMF digit may be received. The TMM may

6

receive the tone signal and search a database for a name corresponding to one or more characteristics of the tone signal, e.g., the frequency. The TMM may create the tone packet and use the name as the identifier for the tone signal. In another embodiment of the invention, the TMM may pass one or more characteristics of the tone signal in the tone packet, e.g., the frequency itself.

The operation of systems **100** and **200**, and the processing logic shown in FIG. **5**, may be better understood by way of example. Assume a caller uses call terminal **104** to initiate a telephone call to call terminal **106** via network **104**. The caller dials the 10 digit telephone number that is received by network **104**. Network **104** initiates call setup using conventional circuit-switched technology via the PSTN and sends the 10 DTMF digits. The circuit-switched signals are received by gateway **202** of system **200**. Gateway **202** includes PSTN interface cards and technology to convert the circuit-switched signals to packet-switched signals. TMM **204** of gateway **202** detects the DTMF signals and begins creating RTP tone packets in accordance with the RFC 2833 Specification and the modifications described herein. The RTP tone packets are routed to call terminal **106** via routing information obtained via gatekeeper **206**.

In accordance with one embodiment of the invention, the RTP tone packets include redundant information in the event one or more RTP tone packets are corrupted or lost during transport to call terminal **106**. The RTP tone packets may resemble, for example, RTP tone packet **400** described with reference to FIG. **4**. As discussed previously, RTP tone packet **400** may include conventional Type Two Information regarding previous tone events, e.g., previously dialed DTMF digits. In accordance with one embodiment of the invention, RTP tone packet **400** may also include Type Three Information as well. It may be appreciated that in some implementations, the Type Two Information may be omitted from RTP tone packet **400** in accordance with bandwidth or other design constraints of network **104**.

In accordance with one embodiment of the invention, call terminal **106** may begin receiving RTP tone packets from gateway **202**. Call terminal **106** may attempt to reconstruct a tone event using the RTP tone packets. In the event one or more RTP tone packets are lost, call terminal **106** may use the Type Three Information to retrieve information carried by the corrupted or lost packets.

Since the RFC 2833 Specification already defines up to five levels of redundancy, it can be appreciated that the Type Three Information may be inserted into RTP tone packets using one or more of these five levels. In this manner, TMM **204** offers more robust and resilient tone recovery functionality while adding relatively little overhead or latency, and in some cases, no overhead or latency at all. It may also be appreciated that the RTP packets may be constructed using any combination of Type Two Information and Type Three Information that meets the design or performance constraints of a particular system.

While certain features of the embodiments of the invention have been illustrated as described herein, many modifications, substitutions, changes and equivalents will now occur to those skilled in the art. It is, therefore, to be understood that the appended claims are intended to cover all such modifications and changes as fall within the true spirit of the embodiments of the invention.

The invention claimed is:

1. A method comprising:

receiving tone information indicating an event of a current tone generated by a caller, wherein the event is pressed at a time but has not ended;

7

creating a tone packet having a first portion and a second portion for the current tone, the first and second portions including redundant information of the event of the current tone that is also carried in at least one tone packet previous to the tone packet, the redundant information to enable the event of the current tone to be reproduced, the redundant information to include time information; and sending the tone packet to a receiver to communicate the current tone.

2. The method of claim 1, creating the tone packet having a third portion, the third portion including tone information associated with an event of a previous tone.

3. The method of claim 1, the tone information represents a tone signal comprising a dual tone multi-frequency digit.

4. The method of claim 1, the tone information includes at least one of a name for the current tone or a frequency for the current tone.

5. The method of claim 1, comprising sending the tone packet in accordance with a protocol to include the real time transport (RTP) protocol.

6. A method comprising:

receiving a first tone packet having a first portion including tone information indicating an event of a current tone generated by a caller, wherein the event is pressed at a time but has not ended; and

receiving a second tone packet having the first portion and a second portion, the first and second portions including redundant information of the event of the current tone that is also carried in the first tone packet, the redundant information to include time information.

7. The method of claim 6, comprising:

reproducing a tone associated with the current tone using the redundant information included in the first and second portions of the second tone packet.

8. The method of claim 6, the second tone packet having a third portion including tone information associated with an event of a previous tone.

9. The method of claim 6, the tone information represents a tone signal comprising a dual tone multi-frequency digit.

10. The method of claim 6, receiving the first tone packet and the second tone packet in accordance with a protocol to include the real time transport (RTP) protocol.

11. The method of claim 6, the tone information includes at least one of a name for a tone associated with the current tone or a frequency for a tone associated with the current tone.

12. A system comprising:

a gateway to receive tone information for a current tone initiated at a call terminal indicating an event of the current tone generated by a caller, wherein the event is pressed at a time but has not ended;

a tone management module to create a tone packet having a first portion and a second portion, the first and second portion including redundant information of the event of the current tone that is also carried in at least one packet previous to the tone packet, the redundant information to enable the event of the current tone to be reproduced, the redundant information to include time information; and a gatekeeper to cause the tone packet to be sent to an intended destination for the current tone.

13. The system of claim 12, the intended destination comprising another call terminal.

14. The system of claim 12, the tone management module to create the tone packet having a third portion that includes tone information associated with an event of a previous tone.

15. The system of claim 12, the tone information received for the current tone represents a tone signal comprising a dual tone multi-frequency digit.

8

16. The system of claim 12, the gatekeeper to cause the tone packet to be sent in accordance with a protocol to include the real time transport (RTP) protocol.

17. At least one non-transitory machine readable medium comprising a plurality of instructions that in response to being executed by a processor cause the processor to:

receive tone information indicating an event of a current tone generated by a caller, wherein the event is pressed at a time but has not ended;

create a tone packet having a first portion and a second portion for the current tone, the first and second portion including redundant information of the event of the current tone that is also carried in at least one packet previous to the tone packet, the redundant information to enable the event associated with the current tone to be reproduced, the redundant information to include time information; and

send the tone packet to a receiver to communicate the current tone.

18. The at least one machine readable medium of claim 17, creating the tone packet having a third portion, the third portion including tone information associated with an event of a previous tone.

19. The at least one machine readable medium of claim 17, the tone information represents a tone signal comprising a dual tone multi-frequency digit.

20. The at least one machine readable medium of claim 17, the tone packet to be sent in accordance with a protocol to include the real time transport (RTP) protocol.

21. At least one non-transitory machine readable medium comprising a plurality of instructions that in response to being executed by a processor cause the processor to:

receive a first tone packet having a first portion including tone information indicating an event of a current tone generated by a caller, wherein the event is pressed at a time but has not ended; and

receive a second tone packet having the first portion and a second portion, the first and second portion including redundant information of the event of the current tone that is also carried in the first tone packet, the redundant information to include time information.

22. The at least one machine readable medium of claim 21, the plurality of instructions to also cause the processor to reproduce a tone associated with the current tone using the redundant information included in the first and second portions of the second tone packet.

23. The at least one machine readable medium of claim 21, the second tone packet having a third portion including tone information associated with an event of a previous tone.

24. The at least one machine readable medium of claim 21, the tone information represents a tone signal comprising a dual tone multi-frequency digit.

25. The at least one machine readable medium of claim 21, the plurality of instructions to also cause the processor to receive the first tone packet and the second tone packet in accordance with a protocol to include the real time transport (RTP) protocol.

26. A method comprising:

receiving tone information indicating an event of a current tone generated by a caller, wherein the event is pressed at a time but has not ended;

creating a real time transport (RTP) packet having a first portion and a second portion for the current tone, the first and second portions including redundant information of the event of the current tone that is also carried in at least one RTP packet previous to the RTP packet, the redundant information to enable a dual tone multi-frequency

9

(DTMF) digit of the current tone to be reproduced, the redundant information to include timestamp information associated with separate durations for the DTMF digit, the separate durations indicated in the first and second portions; and

5 sending the RTP packet to a receiver to communicate the DTMF digit.

27. The method of claim 26, creating the RTP packet having a third portion, the third portion including tone information associated with an event of a previous tone for a separate DTMF digit. 10

28. The method of claim 26, the tone information includes at least one of a name for the DTMF digit or a frequency for the DTMF digit.

29. A method comprising:

15 receiving a first real time transport (RTP) packet having a first portion including tone information for a current tone associated with a dual tone multi-frequency (DTMF) digit and indicating an event of the current tone generated by a caller, wherein the event is pressed at a time but has not ended; and

10

receiving a second RTP packet having the first portion and a second portion, the first and second portions including redundant information of the event of the current tone that is also carried in the first RTP packet, the redundant information to include timestamp information associated with separate durations for the DTMF digit, the separate durations indicated in the first and second portions.

30. The method of claim 29, comprising:

reproducing the DTMF digit associated with the current tone using the redundant information included in the first and second portions of the second RTP packet.

31. The method of claim 29, the second packet having a third portion including tone information associated with an event of a previous tone for a separate DTMF digit. 15

32. The method of claim 29, the tone information includes at least one of a name for a DTMF digit associated with the current tone or a frequency for a DTMF digit associated with the current tone.
