(57) **ABSTRACT**
A wireless access point array having a plurality of access point radios, a monitor radio and an array controller. The array controller includes processes, methods and functions for verifying the operation of the access point radios. The access point radios may be verified by attempting to establish a data connection between the monitor radio and each of the access point radios.

**NODE FAULT IDENTIFICATION IN
WIRELESS LAN ACCESS POINTS****CROSS REFERENCE TO RELATED
APPLICATIONS**

This application claims priority to the provisional patent applications, Ser. No. 60/944,640, titled "NODE FAULT IDENTIFICATION IN WIRELESS LAN ACCESS POINTS," by Kirk Matthews, Dirk I. Gates, Michael B. Rydalch, filed on Jun. 18, 2007, and incorporated herein by reference.

BACKGROUND OF THE INVENTION**1. Field of the Invention**

The invention relates to wireless data communication systems and more particularly to systems and methods for detecting node faults in access points in wireless local area networks.

2. Description of the Related Art

The use of wireless communication devices for data networking is growing at a rapid pace. Data networks that use "WiFi" ("Wireless Fidelity") are relatively easy to install, convenient to use, and supported by the IEEE 802.11 standard. WiFi data networks also provide performance that makes WiFi a suitable alternative to a wired data network for many business and home users.

WiFi networks operate by employing wireless access points to provide users having wireless (or 'client') devices in proximity to the access point with access to data networks. The wireless access points contain a radio that operates according to one of three standards specified in different section of the IEEE 802.11 specification. Radios in access points communicate using omni-directional antennas in order to communicate signals with wireless devices from any direction. The access points are then connected (by hardwired connections) to a data network system that completes the users' access to the Internet.

The three standards that define the radio configurations are:

1. IEEE 802.11a, which operates on the 5 GHz band with data rates of up to 54 Mbps;
2. IEEE 802.11b, which operates on the 2.4 GHz band with data rates of up to 11 Mbps; and
3. IEEE 802.11g, which operates on the 2.4 GHz band with data rates of up to 54 Mbps.

The 802.11b and 802.11g standards provide for some degree of interoperability. Devices that conform to 802.11b may communicate with 802.11g access points. This interoperability comes at a cost as access points will incur additional protocol overhead if any 802.11b devices are connected. Devices that conform to 802.11a may not communicate with either 802.11b or g access points. In addition, while the 802.11a standard provides for higher overall performance, 802.11a access points have a more limited range due to their operation in a higher frequency band.

Each standard defines 'channels' that wireless devices, or clients, use when communicating with an access point. The 802.11b and 802.11g standards each allow for 14 channels. In IEEE Std. 802.11a-1999, 200 channels are defined; each channel centered every 5 MHz from 5000 MHz to 6000 MHz. The 802.11a standard currently allows for 12 channels in the US. The 14 channels provided by 802.11b and g include only 3 channels that are not overlapping. The 12 channels provided by 802.11a are non-overlapping channels. The FCC is expected to allocate 11 additional channels in the 5.47 to 5.725 GHz band.

2

Some WiFi or IEEE 802.11 wireless network access points often contain multiple independently operating bi-directional radio communications nodes. Wireless access point nodes can and do fail for a variety of reasons as diverse as random ionizing radiation disrupting an electronic component, timing or race conditions in the tens of thousands of lines of software and programmable hardware code, and actual component failure due to ageing, thermal cycling, or manufacturing tolerance or error. One advantage of multi-radio access points is that they provide fault tolerant communication between the access point and its associated clients. When one or more radios fail, the remaining radios can continue to provide communications service to the clients associated with the access point.

In order to reduce system degradation, there is a need to reliably identify failed nodes and reactivate or replace them. Present methods of determining failure rely on monitoring data communications between the access points and their clients and reporting the presence or absence of transferred data. However, access point clients typically operate in a relatively autonomous manner when choosing a particular access point node with which to associate. For this reason a lack of associated clients may not, by itself, be a reliable method of failure identification.

There is a need for systems and methods that more reliably identify failed nodes, and to reactivate or replace them.

BRIEF DESCRIPTION OF THE FIGURES

The components in the figures are not necessarily to scale, emphasis instead being placed upon illustrating the principles of the invention. In the figures, like reference numerals designate corresponding parts throughout the different views.

FIG. 1 is a block diagram of a network that uses a wireless access device.

FIG. 2 is a block diagram of a transceiver module in the wireless access device in FIG. 1.

FIG. 3 is a block diagram of a controller in the wireless access device shown in FIG. 1.

FIG. 4 is a diagram illustrating the formation of sectors by the wireless access device of FIG. 1.

FIGS. 5A-E are diagrams illustrating examples of coverage patterns formed by an example of the wireless access device of FIG. 1.

FIG. 6A is a diagram of a wireless access device of FIG. 1 labeled by radio type and number.

FIG. 6B shows coverage patterns formed by the different radio types on the wireless access device.

FIG. 7 illustrates operation of a wireless access device.

FIG. 8 is a flowchart illustrating operation of an example method for identifying node faults.

DETAILED DESCRIPTION

FIG. 1 is a block diagram of network 10 that uses a wireless access device 100 to provide client devices (or "stations"), such as a laptop computer 20, access to data network services available on the Internet 160. The wireless access device 100 is connected to a wired network 120, which may provide a connection to the Internet 160 or other network. Depending on the number of stations and the size of the area of coverage, the network 10 may include additional wireless access devices 130. A network management system 120 may be used to configure and manage the wireless access devices 100, 130.

The wireless access device 100 in FIG. 1 has a substantially circular structure 108 and includes a array controller 102, a plurality of transceiver modules 110, and a network interface

3

114. The transceiver modules **110** contain one or more transceivers, radios, for example, and each transceiver is connected to an antenna **112**. The transceiver modules **110** are also connected to the array controller **102**, which operates to configure the transceiver modules **110** and manage any communications connections involving the transceivers.

The wireless access device **100** shown in FIG. **1** has sixteen antennas **112**. One of ordinary skill in the art will appreciate that any number of antennas may be used. The antennas **112** that correspond to the transceivers in the transceiver modules **110** are disposed near the perimeter of the substantially circular structure **108** of the wireless access device **100**. The antennas **112** are preferably directional antennas configured to transmit and receive signals communicated in a radial direction from the center of the wireless access device **108**. Each antenna **112** covers a portion of the substantially circular area surrounding the wireless access device **100** called a “sector” **Si**. The total area covered by all of the sectors defines a 360° area of coverage of the wireless access device **100**. This means that a station **20** located in a sector of the area of coverage would be able to communicate wirelessly with the antenna **112** corresponding with that sector. Multi-sector coverage is discussed in more detail below with reference to FIGS. **5A-5E**.

The network **10** in FIG. **1** implements well-known standards and protocols used to communicate over the Internet **160**. The transceivers in the wireless access device **100** in FIG. **1** communicate with stations **20** in accordance with the IEEE 802.11 standard (802.11a, 802.11b, 802.11g), which is incorporated herein by reference. The remainder of this specification describes operation of examples of the wireless access device **100** in the context of systems that implement IEEE 802.11a, b, or g. However, the present invention is not limited to systems that implement any particular standard. The wireless access device **100** may operate according to any current or future standard, such as for example, the forthcoming IEEE 802.11n.

The wireless access device **100** in FIG. **1** has four transceiver modules **110**. Each transceiver module **110** contains four transceivers, each of which is programmable. In a preferred configuration, three of the four transceivers (shown in FIG. **1** with antennas labeled ‘a’) in each transceiver module **110** are designated to operate as 802.11a radios. The remaining transceiver (shown in FIG. **1** with antenna labeled ‘abg’) may be programmed to operate according to any of 802.11a, b, or g. Each transceiver is configured to operate on an assigned channel. The channel may be one of the twelve channels available using the 802.11a standard or one of the fourteen channels available using the 802.11b/g standard.

The wireless access device **100** communicates with stations **20** wirelessly. The stations **20** may be any device enabled to communicate wirelessly with the wireless access device **100** such as, without limitation, laptop computers, mobile telephones (for voice-over-LAN, or VOWLAN applications), personal digital assistants, handheld computers, etc. In examples described here, the stations are enabled to operate in accordance with one or more of the 802.11 standards. When the station **20** enters the coverage area of the wireless access device **100**, it may send a request to connect to the access point **160**. The wireless access device **100** may perform an authentication process in a login session. Once authenticated, the user of the station **20** may be connected to the Internet **160**.

FIG. **2** is a block diagram of a transceiver module **210** that may be implemented in the wireless access device **100** shown in FIG. **1**. The transceiver module **210** includes four radios, one of which is an ‘abg’ radio **220** and three of which are ‘a’

4

radios **222**. All four radios **220, 222** include an amplifier **230**, a radio signal processor **240**, and a baseband processor **250**. The four radios **220, 222** communicate with a transceiver module interface **260**, which allows the transceiver module **210** to communicate with the rest of the wireless access device. One of ordinary skill in the art will appreciate that four radios **220, 222** are shown as an example. The transceiver module **210** may also have one, two, or any number of radios.

Each radio **220, 222** connects to an antenna **212**, which transmits and receives radio signals received from the amplifier **230**. As described with reference to FIG. **1**, the antennas **212** are directional antennas, which concentrate signal power in one direction. Directional antennas can therefore cover greater distances than omni-directional antennas used in typical wireless access devices. The multiple radios with radially disposed directional antennas advantageously provides a 360° coverage pattern that is larger than that of radios with omni-directional antennas used in current access points.

The baseband processor **250** processes the digital data that is either being received or transmitted by the radio **220, 222**. The baseband processor **250** implements protocols required for such functions as assembling/disassembling payloads. The baseband processor **250** performs the digital functions required to implement the 802.11 standard. Preferably, the baseband processor **250** is programmable and may be configured for any of the three standards (802.11a, 802.11b, 802.11g). One example of a baseband processor **250** that may be implemented is the Agere WL64040.

The radio signal processor **240** modulates signals to be transmitted and demodulates signals that have been received. The radio signal processor **240** is preferably programmable to implement either the modulation schemes specified by 802.11b/g or 802.11a. One example of a radio signal processor **240** that may be implemented is the Agere WL54040.

The amplifier **230** generates the radio signal to be transmitted by the transceiver **220, 222** and amplifies signals being received by the antenna **212**. One example of an amplifier that may be implemented in the transceiver module **210** is the SiGe Semiconductor SE2535L for the 5 GHz or 802.11a radios, and the SiGe Semiconductor SE2525L for the 2.4 GHz or 802.11b/g radios.

In the transceiver module in FIG. **2**, the amplifier **230**, radio signal processor **240**, and/or baseband processor **250** may be programmable so that the array controller **102** (in FIG. **1**) may control the transceiver module **200** in a manner that provides certain features. For example, the array controller **102** (in FIG. **1**) may control the amplifiers **230** in a manner that makes the coverage pattern of the wireless access device **102** larger or smaller depending on the needs of the implementation. In addition, the baseband processor **250** may communicate information (such as signal strength) about the radio connection between the wireless access device **100** and the stations **20**.

It is noted that the following description refers to transceivers as radios. Those of ordinary skill in the art will appreciate that the term “radio” is not intended as limiting the transceiver to any particular type.

FIG. **3** is a block diagram of an array controller **300** that may be implemented in the wireless access device **100** shown in FIG. **1**. The array controller **300** includes a processor **310**, a packet and queue controller **320**, a medium access controller **330**, a radio interface **340**, and a data network interface **350**.

The processor **310** provides computing resources to the wireless access device. The processor **310** may be any suitable custom or commercial microprocessor, microcontroller, computing chip or other type of processor. The array control-

5

ler 300 also includes supporting circuitry for the processor 310 such as clock circuitry, I/O ports, memory (including Read Only Memory, or ROM, Random Access Memory, or RAM, Flash memory, Programmable Rom or PROM, etc.), direct memory access, etc. The processor 310 may also manage a bus system for communicating with its support circuitry and with the packet and queue controller 320, data network interface 350 and medium access controller 330. In one example, the processor 310 is a Motorola 8540 800 MHz CPU supported by 64 MB expandable system FLASH memory, 128 MB DDR 333 expandable system RAM, and a serial interface (RS232-RJ45 connector). An optional security co-processor may also be included.

The data network interface 350 includes input/output circuitry for communicating over a data network. The array controller 300 implements standards and protocols that allow for communication over the Internet. The data network interface 350 preferably allows for the highest possible speed connection. In one example, the data network interface 350 includes primary and secondary Gigabit Ethernet interfaces, a Fast Ethernet interface, and failover support between the Gigabit Ethernet interfaces.

The packet and queue controller 320 handles receiver and transmitter queues, performs DMA functions, resolves fragmentation, and performs packet translation. The medium access controller 330 provides all IEEE 802.11 MAC services for transceivers. For the wireless access device 100 in FIG. 1, the medium access controller 330 provides 802.11 MAC services for as many as sixteen transceivers. Both the packet and queue controller 320 and the medium access controller 330 are preferably implemented as application specific integrated circuits (ASIC).

The array controller 300 performs the programmed functions that control the wireless access device 100 as an access point. Functions and features of the operations that the array controller 300 performs include:

1. General implementation IEEE 802.11 Access Point functionality.
2. Non-blocking packet processing from/to any radio interface. In typical wireless access devices that employ a single, omni-directional radio, a packet that is being transmitted may block other packets from access to the medium. This may occur in either direction. Stations typically transmit packets to an access point when the medium is not busy. If the medium is busy with packets from other stations, for example, the packet is blocked. Similarly, the access point may be attempting to send a packet to a station. If other packets are being sent to another station, the original packet is blocked from access to the medium. In the wireless access device 100, when a station is blocked from communicating a packet to one radio, it may switch to another radio that is not blocked. If the wireless access device 100 is blocked from sending a packet via one radio, it may switch to another radio.
3. Dynamic automatic channel assignment. The array controller 300 implements algorithms and/or other schemes for assigning channels of the 802.11 standards to the multiple radios. Channels are allocated to radios in a manner that reduces adjacent channel interference (ACI).
4. Directional awareness of where a wireless station is in geographic relationship to the wireless access device 100. The array controller 300 receives information such as signal strength, and for each station, may keep track of how the signal strength changes over time. In addition, even if one radio is locked in and "connected" to a

6

station, another radio may receive signals and thus, "listen" to the station. The signal strength in relation to the specific radios gathering signal information provide the array controller with sufficient information to create a directional awareness of the location of the wireless station.

5. Station mobility services whereby a station can instantly roam from one sector to another without requiring re-authentication of the station. As a wireless station moves in the coverage area space of the wireless access device, the signal strength sensed by the array controller changes. As the signal strength of the station becomes weaker, the radio associated with the adjacent sector locks in and "connects" with the station without requiring re-authentication.
6. Wireless quality of service.
7. Enhanced load balancing of wireless stations.
8. Constant RF monitoring of channel conditions and security threats
9. Wireless Security processing
10. Internal Authentication Server. Typically, authentication takes place at a server or router that is wired to the access points. In the wireless access device 100, authentication may be done by the array controller 300.
11. Wired Networking protocol support.
12. System failover handling and error handling. Because sectors overlap, when a radio fails, the adjacent radios may lock in with stations being handled by the failed radio. In some examples of the wireless access device 100, the array controller 300 may increase power to adjacent sectors to ensure coverage in any area covered by the failed sector. In addition, when multiple access devices are deployed, one wireless access device may increase power and expand a sector to cover area left without service when a radio fails in an adjacent wireless access device.
13. System management functions.

As discussed above, examples of wireless access devices and systems that employ wireless access devices described in this specification (without limitation) operate in the wireless LAN environment established by the IEEE 802.11 standardization body. The IEEE 802.11 standards including (without limitation):

- IEEE 802.11 1999 Edition (ISO/IEC 8802-11: 1999) IEEE Standards for Information Technology—Telecommunications and Information Exchange between Systems—Local and Metropolitan Area Network—Specific Requirements—Part 11: Wireless LAN Medium Access Control (MAC) and Physical Layer (PHY) Specifications
- IEEE 802.11a-1999 (8802-11:1999/Amd 1:2000(E)), IEEE Standard for Information technology—Telecommunications and information exchange between systems—Local and metropolitan area networks—Specific requirements—Part 11: Wireless LAN Medium Access Control (MAC) and Physical Layer (PHY) specifications—Amendment 1: High-speed Physical Layer in the 5 GHz band

IEEE 802.11j-2004 IEEE Standard for Information technology—Telecommunications and information exchange between systems—Local and metropolitan area networks—Specific requirements—Part 11: Wireless LAN Medium Access Control (MAC) and Physical Layer (PHY) specifications—Amendment 7: 4.9 GHz-5 GHz Operation in Japan

All of the above-listed standards are incorporated herein by reference.

Radios operating under 802.11 may operate in one of two frequency bands: the 2.4 GHz band and the 5 GHz band. The IEEE specifies multiple channels within each band (see Table 1). Channels are defined as allocations of frequency spectrum with specified center frequencies and spacing. For example, in the 2.4 GHz band there are 14 defined channels starting at a center frequency of 2.412 GHz and incrementing up to 2.484 GHz at 5 MHz intervals. Channels are considered overlapping if their bands overlap above a certain power threshold. For instance, in the 2.4 GHz region each channel operates with a frequency band of 12 MHz on either side of the center frequency. So with 14 channels defined with center frequencies 5 MHz apart, several of them are overlapping. In fact, there are only three channels (channels 1, 6, and 11) that do not overlap in the 2.4 GHz band. Their center frequencies are 2.412 GHz, 2.437 GHz and 2.462 GHz.).

In the 5 GHz band, the IEEE Std. 802.11a-1999 defines 200 channels; each channel centered every 5 MHz from 5000 MHz to 6000 MHz. The 802.11a standard currently allows for 12 channels in the US. The 12 channels provided by 802.11a

are non-overlapping channels. The FCC is expected to allocate 11 additional channels in the 5.47 to 5.725 GHz band. Those of ordinary skill in the art will appreciate that the channels described herein are for purposes of illustrating an example and not intended as any limitation on the scope of the invention. Embodiments of the present invention that are designed to implement any part of the 802.11 standard may use any set of channels specified by any part of the IEEE 802.11 standard whether such channels are available now or in the future.

TABLE 1

IEEE 802.11 U.S. Radio Channel Assignments			
IEEE 802.11 A (5.0 GHz Band)		IEEE 802.11 B/G (2.4 GHz Band)

		13	2472
		14	2484

The wireless access device **100** in FIG. 1 assigns channels to the sixteen radios in a manner that enhances performance, throughput, coverage area and capacity. Typical access points use one radio with a coverage area defined by an omnidirectional antenna and assigned to a single channel. Therefore, all of the users in the coverage area tune in to the same channel in order to communicate with the access point. In the wireless access device **100** in FIG. 1, each radio forms a different sector defining a portion of a substantially circularly-defined coverage pattern. In addition, each radio is assigned a unique channel so that no two radios in one device communicate over the same channel.

FIG. 4 is a diagram illustrating the formation of sectors by the wireless access device of FIG. 1. The wireless access device **100** has 16 radios **412** divided into groups of four radios **412** mounted on each of four transceiver modules **410**. An array controller **402** is located roughly in the center of the wireless access device **100** where it connects with each of the four transceiver modules **410** at inter-module connections **408**. The inter-module connections **408** contain communication paths (via a bus or set of signal paths on a connector) that implement the interface between the array controller **402** and the radios **412**. One of ordinary skill in the art will appreciate that the wireless access device **100** may have more or fewer than 16 radios. For example, in other embodiments, the wireless access device **100** has 4 radios (e.g. three 'abg' unidirectional radios and one 'abg' omni-directional) or 8 radios (e.g. four 'a' unidirectional radios, three 'abg' unidirectional radios, one 'abg' omni-directional radio) or even 24 radios (anywhere from 16-24 'a' radios and 0-8 'abg' radios). The number of radios is not important so long as multiple radios may be configured to provide a 360° coverage area.

As discussed, each radio **412** contains a directional antenna configured to establish a coverage area in a sector **450** that radiates out from the wireless access device **100**. The radios

412 may be individually controlled such that when they are all operating they may form a coverage pattern that surrounds the wireless access device 100. The coverage pattern created by the wireless access device 100 may be similar to coverage patterns created by existing access points that use one radio radiating out of an omni-directional antenna. However, the wireless access device 100 in FIG. 4 uses sixteen radios 412 radiating out of more powerful directional antennas to create a coverage pattern area that is significantly greater than that of a typical access point. In addition, the sectors 450 created by the radios 412 in the wireless access device 100 advantageously overlap to provide features not currently available in typical access points. The radios 412 are also programmable such that they may be controlled to operate at power levels that allow for coverage patterns that are suited to the layout of the implementation. Examples are discussed below with reference to FIGS. 5A-E.

In FIG. 5A, a wireless access device 100 is implemented in an implementation I with all of the radios in the wireless access device 100 configured to communicate with stations within a coverage area 502. The radios in the wireless access device 100 form sectors. A first sector 530 is shown with an adjacent sector 540 along with an area of overlap 550 formed by the overlap of the first and second sectors 530, 540. FIG. 5A illustrates one of many advantages that the wireless access device 100 has over typical access points. The wireless access device 100 includes programmable and configurable control over the operation of the radios on the wireless access device 100. When deployed, the wireless access devices 100 may be configured to create a coverage pattern that is suitable for by the exact implementation I. For example, in FIG. 5A, the coverage pattern 502 has been configured to conform to the implementation I. The wireless access device 100 may be configured such that the radios that create a set of coverage patterns 522, 524, 526, 528, 530 that project towards a side 580 communicate signals at a lower power limiting the extent of the coverage area created by each radio. This is illustrated by a set of middle sectors 524, 526, 528 covering less distance than outer sectors 522, 530, which cover the corners or the implementation I along the side 580. This implementation I advantageously substantially limits the ability for a station to connect from beyond the wall along the side 580 of implementation I.

FIG. 5B illustrates how the wireless access device 100 may be configured to provide special features in a specific implementation. In FIG. 5B, the wireless access device 100 is implemented in a space 570 in which the resident desires to have wireless Internet access. The space 570 is located with one side 590, which faces an open and public area from which hackers or otherwise unauthorized users may attempt to gain access to the Internet via the wireless access device 100. The wireless access device 100 may be used to provide users in the space 570 with access to the Internet while limiting access by those on the other side of 590. One way as illustrated in FIG. 5B is to place the wireless access device 100 along the side 590 and turn off radios that would create sectors on the other side of 590, and turn on the radios that create sectors in the space 570. Such an implementation would yield a coverage pattern similar to the one shown in FIG. 5B.

FIG. 5C shows how the wireless access device 100 may be configured to limit the affects of obstacles that may cause reflections in the radio signals. Reflections in typical access points may cause multi-path interference. When radio signals reflect off of obstacles, the reflections may reach the station as different signals coming from different directions, or multiple paths. The wireless access device 100 may be configured to avoid multi-path interference by configuring the radios to

avoid generating sectors that could reach the obstacle. In FIG. 5C, the wireless access device 100 is shown generating sectors 520, 540, but not generating any sectors in the direction of obstacle 575.

FIG. 5D illustrates how overlapping sectors may be used to provide radio frequency failover so that stations do not lose connectivity when a radio fails, or is otherwise unavailable. In FIG. 5D, wireless access device 100 has three radios creating a sector each (R1, R2, R3). In FIG. 5E, the wireless access device 100 has lost the radio associated with sector R2. However, sectors R1, R2, R3 advantageously overlap. The wireless access device 100 may switch stations in sector R2 that were connected via the radio that generated sector R2 to the radios that created either of sectors R1 or R3.

FIG. 6A is a diagram of a wireless access device 100 of FIG. 1 labeled by radio type and number. Radios that communicate, or are configured to communicate, as 802.11a radios only are labeled 'a.' Radios that may be programmed or configured to communicate using 802.11a, b, or g radios are labeled 'abg.' The twelve 'a' radios 610 (a1-a12) are assigned a unique one of the twenty-three channels available under the 802.11a standard. Three of the four 'abg' radios are assigned the three non-overlapping channels available under the 802.11b/g standards. The fourth 'abg' radio is implemented as an omni-directional radio in listen mode exclusively.

FIG. 6B shows coverage patterns formed by the different radio types on the wireless access device. The twelve 'a' radios 610 each have a coverage area emanating in a sector that spreads out more than 30°. The sectors of the twelve 'a' radios 610 may combine to form a substantially circular 802.11a coverage pattern 620. Preferably, the sectors are larger than 30° in order to create overlap between the sectors, such as for example, the overlap 650 between sectors 630 and 640. FIG. 6B also shows the three 'abg' radios 611 with the coverage area of more than 120°. The sectors combine to provide a 360° coverage pattern. However, each sector is more than 120° to create overlap between the sectors. The fourth 'abg' radio 613 is configured as an omni-directional radio able to communicate in all directions. The fourth 'abg' radio 613 is used as a monitor or a sniffer radio in a listen-only mode. This radio listens to each channel in sequence to build a table of all stations and access devices. This table may be compared to an administrator controlled list of allowed stations and access devices. Stations and access devices not in the administrator controlled list are termed rogues. One function performed by the fourth 'abg' radio 613 is to detect unauthorized stations in the coverage area.

In an example implementation, the fourth 'abg' radio (or 'M' radio) 613 may be used in the following node fault identifying functions:

- i. Connecting the 'M' radio 613 in the access point array sequentially to each of the other radios in the access point array in order to verify proper operation of each radio within the access point.
- ii. Connecting the 'M' radio 613 in the multi-radio multi-band access point array sequentially to each of the other radios in the access point in order to verify proper operation of each radio within the access point on each of its bands.
- iii. Connecting the 'M' radio 613 in the multi-radio multi-band access point array sequentially to each of the other radios in the access point in order to verify proper operation of each radio within the access point on each of its bands and to software reset any radio not found to be properly operational.
- iv. Connecting the 'M' radio 613 in the multi-radio multi-band access point array sequentially to each of the other

11

radios in the access point in order to verify proper operation of each radio within the access point on each of its bands and to software reset any radio not found to be properly operational. If it is further found that a software reset does not resolve the problem, an alarm may be sent to the system administrator so that the radio may be repaired or replaced.

FIG. 7 is a diagram of a wireless access device **700** connected wirelessly to a plurality of stations **720a-o** via channels allocated to the plurality of radios **a1-a12**, **afg1-afg4** on the wireless access device **700**. The radios are labeled according to their type and radio numbers. Inside the circles representing the radios are numbers identifying the channels assigned to the radio. As shown, radios **a1-a12** and **afg1-afg4** are assigned channels as shown in Table 2 below:

TABLE 2

Radio No.	Channel	Frequency (MHz)
A9	36	5180
A12	40	5200
A3	44	5220
A6	48	5240
A10	52	5260
A1	56	5280
A4	60	5300
A7	64	5320
A11	149	5745
A2	153	5765
A5	157	5785
A8	161	5805
M	—	Monitor radio that can listen and transmit on any abg channel
abg1	1	2412
abg3	6	2437
abg4	11	2462

The radios in the wireless access device **700** are advantageously assigned different channels. The radios in FIG. 7 and the array controller (described above with reference to FIG. 3) are housed within a single enclosure tightly coupled by digital bus. The housing provides a central control point for the sixteen radios that is not tethered by any cabled bus.

The stations **720a-o** in FIG. 7 represents stations attempting to establish data connections with the wireless access device **700**. The arrows indicate the stations' ability to connect to a particular radio as well as the ability of the station to communicate using the appropriate protocol (i.e. 802.11a, b, or g). To illustrate, station **720a** is a target wireless client attaching to the wireless access device **700** using protocols specified by 802.11a. Radios **a5**, **a6**, and **a7** generate sectors that preferably overlap such that station **720a** may connect to either one of the three radios. Each radio is assigned a unique channel that does not overlap with any other channel.

Station **720a** may attempt to establish a data connection with one of the radios **a5**, **a6**, or **a7**. If the radio to which station **720a** connects fails, or is otherwise unable to provide service to station **720a**, the array controller is able to switch the connection with station **720a** over to one of the adjacent radios. The IEEE 802.11a, b, and g protocols permit radios to "listen" to signals being communicated with stations that are connected to another radio. The array controller may obtain data such as signal strength and directional awareness and other factors that allow it to determine which radio is best suited to continue communicating with the station **720a**.

In an example implementation, a monitor station ("M" station) **720b** may be configured as a client to actively con-

12

nect to each of the other radios in the array in a sequential manner. For example, the 'M' station **720b** connects to radio **A1** (station **720g** in FIG. 7) to send and receive a set of packets of data. The 'M' station **720b** then connects to radio **A2** (station **720e**) to send and receive another set of packets. The process continues until the operation of each of the 15 active radios has been verified. If any of the radios are found to be inoperable, the radios may first be issued a software reset command and, if the radios remain inoperable, the radios may be scheduled for physical maintenance or replacement.

The wireless access device **700** is connected to a Gigabit Ethernet port **780**, which provides a direct connection to the user's network.

FIG. 8 is a flowchart illustrating operation of an example method for identifying node faults. At step **802** in FIG. 8, a monitor radio, such as the 'M' radio **720b** described above with reference to FIG. 7, is configured to be un-associated with any clients. At step **803**, the monitor radio is tuned to either a first, or a next, active access point radio's channel number. If the example method in FIG. 8 is starting, the first active access point radio's channel number is used. A list of active access point radios and respective channel numbers may be retrieved from memory as shown at **804** in FIG. 8. Such a list may be based on an example list in Table 2 above.

At step **806**, an attempt is made to authenticate and associate the monitor radio as a client of the access point radio selected from the list **804** in FIG. 8. Decision block **808** determines whether the monitor radio was successfully associated or not. If the monitor radio is successfully associated, the monitor radio attempts to communicate packets of test data. Decision block **812** checks the data received at the selected access point radio to determine if it was accurately transmitted. If the data packets were accurately transmitted, the monitor radio is reset at step **816**.

If at decision block **808**, the selected access point radio was not associated successfully, or, if at step **812**, the data transmitted by the monitor radio is determined to be incorrect, decision block **814** determines whether this is the first attempt to test the selected access point radio. If it is the first attempt, a software reset command is communicated to the selected access point radio at step **818**. Step **806** may then be repeated. If decision block **814** determines that it was not the first attempt, a request for physical maintenance or for replacement of the selected access point radio found to be inoperable, or faulty, as shown at step **820**.

In the described or other example implementations, other forms of feedback or ways of addressing faulty nodes may be used. For example, messages may be communicated over the network, logs may be updated, and status reports may be created or updated. In addition, another access point radio may be selected to associate with the clients of the access point radio deemed to be faulty.

Although the controller **300** depicted in FIG. 3 uses memory, one skilled in the art will appreciate that a substantial part of systems and methods consistent with the present invention may be stored on or read from other machine-readable media, for example, secondary storage devices such as hard disks, floppy disks, and CD-ROMs; a signal received from a network; or other forms of ROM or RAM either currently known or later developed. Further, although specific components of wireless access device **100** are described, one skilled in the art will appreciate that a network access device suitable for use with methods, systems, and articles of manufacture consistent with the present invention may contain additional or different components.

The foregoing description of an implementation has been presented for purposes of illustration and description. It is not

13

exhaustive and does not limit the claimed inventions to the precise form disclosed. Modifications and variations are possible in light of the above description or may be acquired from practicing the invention. For example, the described implementation includes software but the invention may be implemented as a combination of hardware and software or in hardware alone. Note also that the implementation may vary between systems. The claims and their equivalents define the scope of the invention.

What is claimed is:

1. A method for verifying operation of a plurality of access point radios in a wireless access point array comprising:
 - establishing a wireless data connection between a monitor radio and each of the access point radios in the wireless access point array by tuning the monitor radio to each one of the access point radios;
 - attempting to authenticate and associate the monitor radio with each access point radio;
 - transmitting data packets from the monitor radio to each one of the access point radios that are successfully associated with the monitor radio;
 - determining if the data packets were accurately transmitted;
 - identifying each of the access point radios with which the data packets were not accurately transmitted as being faulty nodes;
 - for each access point radio identified as being a faulty node:
 - issuing a radio reset of the faulty node;
 - transmitting data packets from the monitor radio to the faulty node;
 - determining if the data packets were accurately transmitted; and
 - if the data packets were not accurately transmitted, initiating a request for maintenance of the faulty node.
2. The method of claim 1 further comprising the step of identifying each access point radio that failed to associate with the monitor radio as being a faulty node.
3. The method of claim 2 where the step of identifying each access point radio further comprises:
 - for each access point radio identified as a faulty node:
 - issuing a radio reset of the faulty node;
 - attempting to associate the faulty node with the monitor radio; and
 - if the faulty node is not successfully associated with the monitor radio, initiating a request for maintenance of the faulty node.
4. The method of claim 1 further comprising:
 - before the step of establishing a connection with access point radios, retrieving a list of active access point radios from a memory storage device; and
 - performing the steps of establishing the data connection, transmitting packets to the access point radios, checking the accuracy of the transmission, and identifying the faulty nodes for each of the active access point radios in the list.
5. A wireless access point array comprising:
 - a plurality of access point radios for establishing wireless data connections with a plurality of stations;
 - a monitor radio configured to communicate wirelessly with each of the plurality of access point radios; and
 - an array controller connected to the access point radios and the monitor radio, the array controller configured to:
 - verify operation of the access point radios by configuring the monitor radio to attempt to establish wireless data connections with each access point radio;

14

- identify the access point radios that were unable to communicate wirelessly with the monitor radio as faulty nodes; and
- for each access point radio identified as being a faulty node:
 - issuing a radio reset of the faulty node;
 - attempting to establish a wireless data connection with each faulty node; and
 - for each faulty node unable to communicate wirelessly with the monitor radio, initiating a request for maintenance.
6. The wireless access point array of claim 5 where the array controller is further configured to transmit data packets to the access point radios with which the monitor radio was able to establish connections, to verify the accuracy of the transmitted data packets, and to identify the access point radios for which the transmission of the data packets was not accurate as faulty nodes.
7. The wireless access point array of claim 5 further comprising:
 - a data storage device containing a list of access point radios in the wireless access point array.
8. A non-transitory computer readable medium having software for verifying operation of a plurality of access point radios in a wireless access point array comprising:
 - logic configured for establishing a wireless data connection between a monitor radio and each of the access point radios in the wireless access point array by tuning the monitor radio to each one of the access point radios;
 - logic configured for transmitting data packets to each one of the access point radios that are successfully associated with the monitor radio;
 - logic configured for checking if the data packets were accurately transmitted;
 - logic configured for identifying each of the access point radios with which the data packets were not accurately transmitted as being faulty nodes; and
 - logic configured for:
 - issuing a radio reset of each faulty node with which data packets were not accurately transmitted;
 - transmitting data packets from the monitor radio to each of the faulty nodes;
 - determining if the data packets were accurately transmitted; and
 - initiating a request for maintenance of each faulty node with which data packets were not accurately transmitted.
9. The non-transitory computer readable medium of claim 8 where the logic configured for establishing the data connection further comprises:
 - logic configured for attempting to authenticate and associate the monitor radio with each access point radio; and,
 - logic configured for identifying access point radios that failed to associate with the monitor radio as being faulty nodes.
10. The non-transitory computer readable medium of claim 9 where the logic configured for identifying access point radios that failed to associate with the monitor radio as being faulty nodes further comprises:
 - logic configured for issuing a radio reset of each of the faulty nodes;
 - logic configured for attempting to associate each of the faulty nodes with the monitor radio; and
 - logic configured for initiating a request for maintenance for any faulty node not successfully associated with the monitor radio.

11. The non-transitory computer readable medium of claim
8 further comprising:
logic configured for performing before establishing a wire-
less data connection with the access point radios, retriev-
ing a list of active access point radios from a memory 5
storage device; and
logic configured for performing the steps of establishing
the wireless data connection, transmitting packets to the
access point radios, checking the accuracy of the trans-
mission, and identifying the faulty nodes for each of the 10
active access point radios in the list.
