(57) **ABSTRACT**

Systems and methodologies are described that facilitate recovering from error due to false detection of completion signals at an access terminal. An access terminal specific request signal can be sent to a target base station to initiate handoff or semi-connected state exit. A completion signal can be transferred in response to the access terminal specific request signal. To mitigate errors stemming from false detection of the completion signal at the access terminal, forward link and reverse link confirmation signals can be transferred to confirm successful handoff or connected state re-entry completion. For example, the access terminal can determine handoff or re-entry to be successful when a forward link confirmation signal is detected prior to expiration of a timer. Moreover, the forward link and reverse link confirmation signals can each include more CRC bits as compared to a number of CRC bits included in the completion signal.

**RECOVERY FROM HANDOFF ERROR DUE
TO FALSE DETECTION OF HANDOFF
COMPLETION SIGNAL AT ACCESS
TERMINAL**

CROSS-REFERENCE TO RELATED
APPLICATIONS

This application claims the benefit of U.S. Provisional Patent application Ser. No. 60/946,128 entitled “METHODS AND APPARATUSES FOR RECOVERING FROM HANDOFF ERROR DUE TO FALSE DETECTION OF LINK ASSIGNMENT BLOCK (LAB) AT ACCESS TERMINAL” which was filed Jun. 25, 2007. The entirety of the aforementioned application is herein incorporated by reference.

BACKGROUND

I. Field

The following description relates generally to wireless communications, and more particularly to confirming handoff to mitigate impact of false detection of a handoff completion signal in a wireless communication system.

II. Background

Wireless communication systems are widely deployed to provide various types of communication; for instance, voice and/or data can be provided via such wireless communication systems. A typical wireless communication system, or network, can provide multiple users access to one or more shared resources (e.g., bandwidth, transmit power, . . .). For instance, a system can use a variety of multiple access techniques such as Frequency Division Multiplexing (FDM), Time Division Multiplexing (TDM), Code Division Multiplexing (CDM), Orthogonal Frequency Division Multiplexing (OFDM), and others.

Generally, wireless multiple-access communication systems can simultaneously support communication for multiple access terminals. Each access terminal can communicate with one or more base stations via transmissions on forward and reverse links. The forward link (or downlink) refers to the communication link from base stations to access terminals, and the reverse link (or uplink) refers to the communication link from access terminals to base stations. This communication link can be established via a single-in-single-out, multiple-in-single-out or a multiple-in-multiple-out (MIMO) system.

MIMO systems commonly employ multiple (N_T) transmit antennas and multiple (N_R) receive antennas for data transmission. A MIMO channel formed by the N_T transmit and N_R receive antennas can be decomposed into N_S independent channels, which can be referred to as spatial channels, where $N_S \leq \{N_T, N_R\}$. Each of the N_S independent channels corresponds to a dimension. Moreover, MIMO systems can provide improved performance (e.g., increased spectral efficiency, higher throughput and/or greater reliability) if the additional dimensionalities created by the multiple transmit and receive antennas are utilized.

MIMO systems can support various duplexing techniques to divide forward and reverse link communications over a common physical medium. For instance, frequency division duplex (FDD) systems can utilize disparate frequency regions for forward and reverse link communications. Further, in time division duplex (TDD) systems, forward and reverse link communications can employ a common frequency region so that the reciprocity principle allows estimation of the forward link channel from reverse link channel.

Wireless communication systems oftentimes employ one or more base stations that provide a coverage area. A typical base station can transmit multiple data streams for broadcast, multicast and/or unicast services, wherein a data stream may be a stream of data that can be of independent reception interest to an access terminal. An access terminal within the coverage area of such base station can be employed to receive one, more than one, or all the data streams carried by the composite stream. Likewise, an access terminal can transmit data to the base station or another access terminal.

Handoffs oftentimes are utilized in wireless communication systems to transfer ongoing calls, data sessions, etc. from a source base station to a target base station. For instance, an access terminal can request to handoff from the source base station to the target base station. Typically, upon sending a handoff request signal to the target base station, the access terminal listens for a handoff completion signal sent from the target base station. Receipt of the handoff completion signal commonly results in the handoff to the target base station being completed. However, this technique can be susceptible to false handoff completion signal detection by the access terminal. By way of illustration, due to fading errors, physical channel errors, and so forth, when the target base station has not transmitted a handoff completion signal over the downlink, the access terminal can improperly believe such handoff completion signal was sent by the target base station.

False positive detection of the handoff completion signal can deleteriously impact overall wireless communication system performance. The access terminal can be looking for a handoff completion signal from the target base station to complete handoff when employing conventional techniques. Further, the access terminal can see a false handoff completion signal and think that handoff is complete. Moreover, the target base station has not sent a handoff completion signal and does not have knowledge of such handoff. Accordingly, the target base station is not transmitting power control commands, the access terminal is being power controlled by random power control commands (e.g., power is undergoing random: drift, . . .) and is not being served (e.g., not receiving data packets from the target base station, . . .). Thus, such a scenario results in loss of connectivity for the access terminal as well as interference to other users (e.g., on a reverse link channel such as a reverse link data channel, a reserve link control channel, Reverse CDMA Control Channel (R-CD-CCH), . . .).

SUMMARY

The following presents a simplified summary of one or more embodiments in order to provide a basic understanding of such embodiments. This summary is not an extensive overview of all contemplated embodiments, and is intended to neither identify key or critical elements of all embodiments nor delineate the scope of any or all embodiments. Its sole purpose is to present some concepts of one or more embodiments, in a simplified form as a prelude to the more detailed description that is presented later.

In accordance with one or more embodiments and corresponding disclosure thereof, various aspects are described in connection with facilitating recovery from error due to false detection of completion signals at an access terminal. An access terminal specific request signal can be sent to a target base station to initiate handoff or semi-connected state exit. A completion signal can be transferred in response to the access terminal specific request signal. To mitigate errors stemming from false detection of the completion signal at the access terminal, forward link and reverse link confirmation signals

can be transferred to confirm successful handoff or connected state re-entry completion. For example, the access terminal can determine handoff or re-entry to be successful when a forward link confirmation signal is detected prior to expiration of a timer. Moreover, the forward link and reverse link confirmation signals can each include more CRC bits as compared to a number of CRC bits included in the completion signal.

According to related aspects, a method that facilitates mitigating error associated with false detection of completion signals in a wireless communication environment is described herein. The method can include transmitting an access terminal specific request signal to a target base station. Further, the method can comprise detecting a completion signal in response to the request signal. The method can also include starting a timer upon detecting the completion signal. Moreover, the method can include confirming transmission of the completion signal from the target base station by determining whether a forward link confirmation signal is received from the target base station prior to expiration of the timer.

Another aspect relates to a wireless communications apparatus. The wireless communications apparatus can include a memory that retains instructions related to sending an access terminal specific request signal to a target base station, receiving a completion signal in response to the request signal, initiating a timer upon receiving the completion signal, and confirming transmission of the completion signal from the target base station by identifying whether a forward link confirmation signal is obtained from the target base station prior to expiration of a timer. Further, the wireless communications apparatus can include a processor, coupled to the memory, configured to execute the instructions retained in the memory.

Yet another aspect relates to a wireless communications apparatus that enables utilizing an error recovery scheme in a wireless communication environment. The wireless communications apparatus can include means for transferring an access terminal specific request signal to a target base station. Moreover, the wireless communications apparatus can include means for initiating a timer when a completion signal is detected. Further, the wireless communications apparatus can include means for confirming transmission of the completion signal from the target base station by determining whether a forward link confirmation signal is obtained before expiration of the timer.

Still another aspect relates to a computer program product that can comprise a computer-readable medium. The computer-readable medium can include code for transferring an access terminal specific request signal to a target base station. Further, the computer-readable medium can include code for initiating a timer when a completion signal is detected. Moreover, the computer-readable medium can comprise code for confirming transmission of the completion signal from the target base station by determining whether a forward link confirmation signal is obtained before expiration of the timer.

In accordance with another aspect, an apparatus in a wireless communication system can include a processor, wherein the processor can be configured to transmit an access terminal specific request signal to a target base station. The processor can also be configured to detect a completion signal in response to the request signal. Moreover, the processor can be configured to start a timer upon detecting the completion signal. Further, the processor can be configured to confirm transmission of the completion signal from the target base station by determining whether a forward link confirmation signal is received from the target base station prior to expiration of the timer.

According to other aspects, a method that facilitates recovering from false completion signal detection in a wireless communication environment is described herein. The method can include receiving an access terminal specific request signal from an access terminal. Further, the method can include transmitting a completion signal to the access terminal in response to the request signal, the completion signal indicates resources assigned to the access terminal. Moreover, the method can include transmitting a forward link confirmation signal to the access terminal, the forward link confirmation signal enables the access terminal to confirm receipt of the completion signal.

Yet another aspect relates to a wireless communications apparatus that can include a memory that retains instructions related to obtaining an access terminal specific request signal from an access terminal, sending a completion signal to the access terminal in response to the request signal, the completion signal indicates a non-zero amount of resources allocated to the access terminal, and sending a forward link confirmation signal to the access terminal, the forward link confirmation signal enables the access terminal to confirm receipt of the completion signal. Further, the wireless communications apparatus can comprise a processor, coupled to the memory, configured to execute the instructions retained in the memory.

Another aspect relates to a wireless communications apparatus that enables mitigating error associated with false completion signal detection in a wireless communication environment. The wireless communications apparatus can include means for analyzing an obtained request signal specific to an access terminal. Moreover, the wireless communications apparatus can comprise means for sending a completion signal to the access terminal based upon the request signal. Further, the wireless communications apparatus can include means for transmitting a forward link confirmation signal to the access terminal that allows the access terminal to confirm receipt of the completion signal.

Still another aspect relates to a computer program product that can comprise a computer-readable medium. The computer-readable medium can include code for evaluating an obtained request signal specific to an access terminal. Further, the computer-readable medium can comprise code for transferring a completion signal to the access terminal based upon the request signal, the completion signal indicates a non-zero amount of resources allocated to the access terminal. Moreover, the computer-readable medium can include code for transferring a forward link confirmation signal to the access terminal that allows the access terminal to confirm receipt of the completion signal.

In accordance with another aspect, an apparatus in a wireless communication system can include a processor, wherein the processor can be configured to receive an access terminal specific request signal from an access terminal. Further, the processor can be configured to transmit a completion signal to the access terminal in response to the request signal, the completion signal indicates resources assigned to the access terminal. Moreover, the processor can be configured to transmit a forward link confirmation signal to the access terminal, the forward link confirmation signal enables the access terminal to confirm receipt of the completion signal.

To the accomplishment of the foregoing and related ends, the one or more embodiments comprise the features hereinafter fully described and particularly pointed out in the claims. The following description and the annexed drawings set forth in detail certain illustrative aspects of the one or more embodiments. These aspects are indicative, however, of but a few of the various ways in which the principles of various

embodiments can be employed and the described embodiments are intended to include all such aspects and their equivalents.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is an illustration of a wireless communication system in accordance with various aspects set forth herein.

FIG. 2 is an illustration of an example system that enables recovering from false detection of handoff completion signals in a wireless communication environment.

FIG. 3 is an illustration of an example access terminal state diagram in accordance with various aspects of the subject disclosure.

FIG. 4 is an illustration of an example system that supports handing off while mitigating error related to false detection of handoff completion signals in a wireless communication environment.

FIG. 5 is an illustration of an example base station state diagram in accordance with various aspects of the subject disclosure.

FIG. 6 is an illustration of an example system that enables compensating for handoff completion signal detection error in a wireless communication environment.

FIG. 7 is an illustration of an example system that enables confirming an access grant utilized for transitioning from a semi-connected state in a wireless communication environment.

FIG. 8 is an illustration of an example methodology that facilitates mitigating error associated with false detection of completion signals in a wireless communication environment.

FIG. 9 is an illustration of an example methodology that facilitates recovering from false completion signal detection in a wireless communication environment.

FIG. 10 is an illustration of an example access terminal that recovers from erroneous completion signal detection in a wireless communication system.

FIG. 11 is an illustration of an example system that facilitates mitigating false detection of completion signals in a wireless communication environment.

FIG. 12 is an illustration of an example wireless network environment that can be employed in conjunction with the various systems and methods described herein.

FIG. 13 is an illustration of an example system that enables utilizing an error recovery scheme in a wireless communication environment.

FIG. 14 is an illustration of an example system that enables mitigating error associated with false completion signal detection in a wireless communication environment.

DETAILED DESCRIPTION

Various embodiments are now described with reference to the drawings, wherein like reference numerals are used to refer to like elements throughout. In the following description, for purposes of explanation, numerous specific details are set forth in order to provide a thorough understanding of one or more embodiments. It may be evident, however, that such embodiment(s) may be practiced without these specific details. In other instances, well-known structures and devices are shown in block diagram form in order to facilitate describing one or more embodiments.

As used in this application, the terms “component,” “module,” “system,” and the like are intended to refer to a computer-related entity, either hardware, firmware, a combination of hardware and software, software, or software in execution.

For example, a component can be, but is not limited to being, a process running on a processor, a processor, an object, an executable, a thread of execution, a program, and/or a computer. By way of illustration, both an application running on a computing device and the computing device can be a component. One or more components can reside within a process and/or thread of execution and a component can be localized on one computer and/or distributed between two or more computers. In addition, these components can execute from various computer readable media having various data structures stored thereon. The components can communicate by way of local and/or remote processes such as in accordance with a signal having one or more data packets (e.g., data from one component interacting with another component in a local system, distributed system, and/or across a network such as the Internet with other systems by way of the signal).

The techniques described herein can be used for various wireless communication systems such as code division multiple access (CDMA), time division multiple access (TDMA), frequency division multiple access (FDMA), orthogonal frequency division multiple access (OFDMA), single carrier-frequency division multiple access (SC-FDMA) and other systems. The terms “system” and “network” are often used interchangeably. A CDMA system can implement a radio technology such as Universal Terrestrial Radio Access (UTRA), CDMA2000, etc. UTRA includes Wideband-CDMA (W-CDMA) and other variants of CDMA. CDMA2000 covers IS-2000, IS-95 and IS-856 standards. A TDMA system can implement a radio technology such as Global System for Mobile Communications (GSM). An OFDMA system can implement a radio technology such as Evolved UTRA (E-UTRA), Ultra Mobile Broadband (UMB), IEEE 802.11 (Wi-Fi), IEEE 802.16 (WiMAX), IEEE 802.20, Flash-OFDM, etc. UTRA and E-UTRA are part of Universal Mobile Telecommunication System (UMTS). 3GPP Long Term Evolution (LTE) is an upcoming release of UMTS that uses E-UTRA, which employs OFDMA on the downlink and SC-FDMA on the uplink.

Single carrier frequency division multiple access (SC-FDMA) utilizes single carrier modulation and frequency domain equalization. SC-FDMA has similar performance and essentially the same overall complexity as those of an OFDMA system. A SC-FDMA signal has lower peak-to-average power ratio (PAPR) because of its inherent single carrier structure. SC-FDMA can be used, for instance, in uplink communications where lower PAPR greatly benefits access terminals in terms of transmit power efficiency. Accordingly, SC-FDMA can be implemented as an uplink multiple access scheme in 3GPP Long Term Evolution (LTE) or Evolved UTRA.

Furthermore, various embodiments are described herein in connection with an access terminal. An access terminal can also be called a system, subscriber unit, subscriber station, mobile station, mobile, remote station, remote terminal, mobile device, user terminal, terminal, wireless communication device, user agent, user device, or user equipment (UE). An access terminal can be a cellular telephone, a cordless telephone, a Session Initiation Protocol (SIP) phone, a wireless local loop (WLL) station, a personal digital assistant (PDA), a handheld device having wireless connection capability, computing device, or other processing device connected to a wireless modem. Moreover, various embodiments are described herein in connection with a base station. A base station can be utilized for communicating with access terminal(s) and can also be referred to as an access point, Node B, Evolved Node B (eNodeB) or some other terminology.

Moreover, various aspects or features described herein can be implemented as a method, apparatus, or article of manufacture using standard programming and/or engineering techniques. The term “article of manufacture” as used herein is intended to encompass a computer program accessible from any computer-readable device, carrier, or media. For example, computer-readable media can include but are not limited to magnetic storage devices (e.g., hard disk, floppy disk, magnetic strips, etc.), optical disks (e.g., compact disk (CD), digital versatile disk (DVD), etc.), smart cards, and flash memory devices (e.g., EPROM, card, stick, key drive, etc.). Additionally, various storage media described herein can represent one or more devices and/or other machine-readable media for storing information. The term “machine-readable medium” can include, without being limited to, wireless channels and various other media capable of storing, containing, and/or carrying instruction(s) and/or data.

Referring now to FIG. 1, a wireless communication system **100** is illustrated in accordance with various embodiments presented herein. System **100** comprises a base station **102** that can include multiple antenna groups. For example, one antenna group can include antennas **104** and **106**, another group can comprise antennas **108** and **110**, and an additional group can include antennas **112** and **114**. Two antennas are illustrated for each antenna group; however, more or fewer antennas can be utilized for each group. Base station **102** can additionally include a transmitter chain and a receiver chain, each of which can in turn comprise a plurality of components associated with signal transmission and reception (e.g., processors, modulators, multiplexers, demodulators, demultiplexers, antennas, etc.), as will be appreciated by one skilled in the art.

Base station **102** can communicate with one or more access terminals such as access terminal **116** and access terminal **122**; however, it is to be appreciated that base station **102** can communicate with substantially any number of access terminals similar to access terminals **116** and **122**. Access terminals **116** and **122** can be, for example, cellular phones, smart phones, laptops, handheld communication devices, handheld computing devices, satellite radios, global positioning systems, PDAs, and/or any other suitable device for communicating over wireless communication system **100**. As depicted, access terminal **116** is in communication with antennas **112** and **114**, where antennas **112** and **114** transmit information to access terminal **116** over a forward link **118** and receive information from access terminal **116** over a reverse link **120**. Moreover, access terminal **122** is in communication with antennas **104** and **106**, where antennas **104** and **106** transmit information to access terminal **122** over a forward link **124** and receive information from access terminal **122** over a reverse link **126**. In a frequency division duplex (FDD) system, forward link **118** can utilize a different frequency band than that used by reverse link **120**, and forward link **124** can employ a different frequency band than that employed by reverse link **126**, for example. Further, in a time division duplex (TDD) system, forward link **118** and reverse link **120** can utilize a common frequency band and forward link **124** and reverse link **126** can utilize a common frequency band.

Each group of antennas and/or the area in which they are designated to communicate can be referred to as a sector of base station **102**. For example, antenna groups can be designed to communicate to access terminals in a sector of the areas covered by base station **102**. In communication over forward links **118** and **124**, the transmitting antennas of base station **102** can utilize beamforming to improve signal-to-noise ratio of forward links **118** and **124** for access terminals **116** and **122**. Also, while base station **102** utilizes beamform-

ing to transmit to access terminals **116** and **122** scattered randomly through an associated coverage, access terminals in neighboring cells can be subject to less interference as compared to a base station transmitting through a single antenna to all its access terminals.

System **100** provides mechanisms for recovering from handoff error due to false detection of handoff completion signals at access terminals **116**, **122**. A particular access terminal (e.g., access terminal **116**, access terminal **122**, . . .) can initiate handoff from a source base station to a target base station (e.g., base station **102** can be the target base station such that the particular access terminal transitions to base station **102** from a disparate base station (not shown), base station **102** can be the source base station such that the particular access terminal transitions from base station **102** to a disparate base station (not shown), . . .) by sending a handoff request signal to the target base station to which the particular access terminal desires to transition (e.g., the handoff request signal can be sent while the particular access terminal is in a Try to Handoff state, . . .). The handoff request signal can be a terminal specific signal that includes information pertaining to an identity of the particular access terminal from which such signal is transmitted. Thereafter, the particular access terminal can monitor a forward link channel for a handoff completion signal transmitted from the target base station. Upon detecting the handoff completion signal (whether or not such detection of the handoff completion signal is erroneous), the particular access terminal can transition to a Confirm Handoff state. Further, while in Confirm Handoff state, the particular access terminal awaits a forward link confirmation signal from the target base station. Moreover, the particular access terminal can send a reverse link confirmation signal to the target base station to enable the target base station to confirm that the handoff has been completed. If the forward link confirmation signal is received from the target base station within a certain timeout, then the particular access terminal can transition to Handoff Complete state. Alternatively, if the forward link confirmation signal is not attained within a certain timeout, then the particular access terminal can return to Try to Handoff state.

The scheme used by system **100** can improve error recovery. For instance, system **100** can rely upon access terminals **116**, **122** confirming handoff using forward link confirmation signal reception. The forward link confirmation signals, for example, can be a forward link (FL) packet, an acknowledgement (ACK) to a reverse link (RL) packet, and the like. Thus, a data packet with 24 bits of cyclic redundancy check (CRC) can be used to confirm the handoff (e.g., rather than 16 bits of CRC as used for the handoff completion signal, . . .). Moreover, base station **102** (as well as any disparate base station(s)) can assist access terminals **116**, **122** by assigning resources in response to received handoff request signals.

False handoff confirmation signal detection can occur if there is cyclic redundancy check (CRC) failure on a forward link control segment (FLCS) from the target base station while the access terminal is trying to effectuate handoff. The CRC can be 16 bits, and the access terminal can be looking for a specific header (e.g., the header can be 2 bits, a particular value for the header can indicate handoff completion, . . .), so the overall probability can be on the order of 2^{-18} . For instance, if there are about 5 handoff completion signals per frame, and the access terminal waits for several frames (e.g., the access terminal can wait 20 frames, . . .) before typical handoff is complete, then the actual probability can be higher (e.g., about a factor of 100 larger, . . .). Hence, the false handoff completion signal probability can be 4×10^{-4} . For one handoff every 10 seconds, this can result in one false handoff

completion signal every 2.5E04 seconds (e.g., about 7 hours, . . .) for a given access terminal. Thus, false handoff completion signal detection can occur frequently when considering a system wide perspective.

Accordingly, system **100** addresses the foregoing by mitigating the error scenario where the access terminal thinks handoff is complete to a target base station, while the target base station thinks it is non-serving. More particularly, system **100** can utilize a two state scheme before the access terminal can conclude that the handoff is complete. For example, the first state (e.g., Try to Handoff state, . . .) can be associated with a false handoff completion signal probability on the order of 10^{-4} . Further, while in the second state (e.g., Confirm Handoff state, . . .), the access terminal can obtain a forward link confirmation signal (e.g., FL packet, ACK to RL packet, . . .); the probability of false ACK to RL packet or false FL packet can be better than 10^{-3} . The combined probability of false detection while in these two states can be 10^{-7} as opposed to a probability on the order of 10^{-4} which is commonly encountered with conventional techniques.

It is to be appreciated that the claimed subject matter contemplates any type of handoff. Although much of the discussion herein refers to handoff from a source base station to a target base station, it is to be appreciated that handoff can be from a source sector to a target sector. Further, the source sector and the target sector can be associated with disparate base stations and/or a common base station.

Turning to FIG. 2, illustrated is a system **200** that enables recovering from false detection of handoff completion signals in a wireless communication environment. System **200** includes an access terminal **202** that can transmit and/or receive information, signals, data, instructions, commands, bits, symbols, and the like to and/or from one or more base stations (not shown). Access terminal **202** can further include a handoff requester **204** and a handoff confirmer **206**.

According to an illustration, a decision for access terminal **202** to handoff to a target base station can be made while access terminal **202** is being served by a source base station (e.g. prior serving base station, . . .). For instance, access terminal **202** (e.g., handoff requester **204** of access terminal **202**, . . .) can yield such decision; however, the claimed subject matter contemplates this decision being made by a base station (e.g., the source base station, the target base station, a disparate base station, . . .) or any disparate component (e.g., disparate access terminal, network node, . . .) in the wireless communication environment. By way of further example, request (REQ) based handoff, channel quality indicator (CQI) based handoff, or access based handoff can be utilized. Accordingly, handoff requester **204** can make a handoff decision based upon forward link (FL) pilot measurements, Reverse Channel Quality Indicator Channel (R-CQICH) erasure indicators, and so forth.

When the decision to handoff is made by (or communicated to) access terminal **202**, access terminal **202** can transition to a Try to Handoff state. Further, handoff requester **204** can generate and/or transmit a handoff request signal. Handoff requester **204** can select a target base station, for example. Moreover, handoff requester **204** can send the handoff request signal to the target base station over the reverse link. The handoff request signal transferred by handoff requester **204** can be specific to access terminal **202** (e.g., the handoff request signal can include information related to an identity of access terminal **202**, . . .).

After transferring the handoff request signal, access terminal **202** awaits a handoff completion signal (e.g., transmitted by the target base station). The handoff completion signal can be sent over the forward link. The handoff completion signal

can be, for example, a reverse link assignment block (RLAB), a forward link assignment block (FLAB), an AccessGrant, or the like.

Handoff confirmer **206** (and/or access terminal **202** in general) can monitor for the handoff completion signal. Upon detecting the handoff completion signal, handoff confirmer **206** can transition access terminal **202** to a Confirm Handoff state. Confirm Handoff state can be employed to mitigate impact associated with false handoff completion signal detection. While in Confirm Handoff state, handoff confirmer **206** can monitor the forward link for a forward link confirmation signal. The forward link confirmation signal can be a forward link (FL) packet, an acknowledgement (ACK) to a reverse link (RL) packet, and so forth. Further, the forward link confirmation signal can have a low probability of false detection. Additionally, handoff confirmer **206** can send a reverse link confirmation signal to the target base station. The reverse link confirmation signal can be a reverse link (RL) packet, a forward link (FL) packet acknowledgement (ACK), or the like.

Handoff confirmer **206** can further include a timer **208**. Timer **208** can track an amount of time that has elapsed since detection of the handoff completion signal. Timer **208** can continue to track the elapsed time until handoff confirmer **206** (or access terminal **202** in general) obtains the forward link confirmation signal. Further, timer **208** can indicate that an amount of time greater than a threshold has passed since receipt of the handoff completion signal without receipt of the forward link confirmation signal. The threshold time limit employed by timer **208** can be preset, dynamically determined, and so forth. According to an example, the threshold time duration can be 50 ms; however, the claimed subject matter is not so limited.

When handoff confirmer **206** determines that the forward link confirmation signal has been obtained prior to expiration of the threshold time period as recognized using timer **208**, access terminal **202** can transition to Handoff Complete state. Thus, access terminal **202** can be served by the target base station. Alternatively, when handoff confirmer **206** recognizes that the threshold time period expired prior to receipt of the forward link confirmation signal (e.g., as determined via timer **208**), access terminal **202** can return to Try to Handoff state. Thus, if handoff confirmation timer **208** expires and/or handoff requester **204** yields a disparate decision to handoff to a disparate base station (other than the target base station), access terminal **202** can return to Try to Handoff state.

Now referring, to FIG. 3, illustrated is an example access terminal state diagram **300**. By way of illustration, state diagram **300** can represent states and transitions between states associated with access terminal **202** of FIG. 2. State diagram **300** includes three states: Handoff Complete state **302**, Try to Handoff state **304**, and Confirm Handoff state **306**. In comparison, conventional schemes typically lack a state similar to Confirm Handoff state **306**.

While being served by a base station, an access terminal can be in Handoff Complete state **302**. Upon a decision to handoff being effectuated, the access terminal can switch to Try to Handoff state **304**. By way of illustration, while in Try to Handoff state **304**, the access terminal can send a handoff request signal (e.g., REQ, . . .) with non-zero buffer size even if a buffer associated with the access terminal is empty when REQ based handoff is utilized. By way of further example, normal operation can be employed by the access terminal (e.g., for sending the handoff request signal, . . .) while in Try to Handoff state **304** when CQI based handoff or access based handoff is used. Thus, with CQI based handoff or access based handoff, a handoff request signal can be sent by the

access terminal to the target base station while in Try to Handoff state **304**, and the access terminal can monitor for a handoff completion signal from the base station.

According to an example where REQ based handoff is employed, a request channel can be used by the access terminal to request reverse link OFDMA resources; when OFDMA resources are assigned, the access terminal can send a reverse link data packet. During handoff while in Try to Handoff state **304**, the access terminal sends the handoff request signal to the target base station. Based on the request, the target base station can realize that the access terminal desires handoff to happen, and thus, the target base station can transfer an RLAB to the access terminal indicating that the target base station has recognized the request of the access terminal and has granted the handoff. Under conventional scenarios, the handoff request signal sent to the target base station can be a request to handoff that lacks a request for resources (e.g., since the access terminal can be handing off because of channel conditions when it lacks data to be transmitted, zero request signal, . . .). In contrast, even when the access terminal lacks data to be sent, the handoff request signal can request a certain amount of resources on the reverse link which can be utilized for Confirm Handoff state **306**.

When a handoff completion signal (e.g. RLAB, FLAB, AccessGrant, . . .) is detected, the access terminal can switch to Confirm Handoff state **306** from Try to Handoff state **304**. According to an illustration, if an RLAB is received by the access terminal, then the access terminal can transmit a NULL packet instead of erasure sequences in response; however, the claimed subject matter is not so limited. Further, on entering Confirm Handoff state **306**, a timer with a threshold duration can start. For instance, the duration can be preset, dynamically determined, or the like. Pursuant to an example, the duration can be 50 ms; however, it is contemplated that any duration can be employed. Moreover, if the timer expires prior to receiving a forward link confirmation signal, then the access terminal transitions to Try to Handoff state **304** from Confirm Handoff state **306**. Similarly, if a decision to handoff to a base station other than the target base station is effectuated while the access terminal is in Confirm Handoff state **306**, then the access terminal can switch back to Try to Handoff state **304**.

According to another example, if the access terminal remains in Confirm Handoff state **306** without receiving the forward link confirmation signal or returns to Try to Handoff state **304** upon expiration of the timer prior to receiving the forward link confirmation signal, then the access terminal can try to perform reconfirmation. Following this example, if handoff was initiated by sending access probes, then the access terminal can send access probes again. Further, if handoff was initiated by sending either a CQI signal or a REQ signal, then the access terminal can continue to send the CQI signal or the REQ signal until confirmation is attained. The foregoing allows the base station to detect a second handoff request signal (e.g., in case of the base station missing the first handoff request signal, . . .) and send a second completion signal.

While in Confirm Handoff state **306**, when a forward link confirmation signal is obtained by the access terminal, the access terminal transitions to Handoff Complete state **302**. The forward link confirmation signal can be an ACK to an RL packet, an FL packet, and so forth. Further, the forward link confirmation signal can have a low probability of false detection. The forward link confirmation signal is used by the access terminal to confirm handoff to the target base station. Moreover, when in Confirm Handoff state **306**, the access

terminal can transmit a reverse link confirmation signal that can be employed by the target base station to verify handoff completion.

With reference to FIG. 4, illustrated is a system **400** that supports handing off while mitigating error related to false detection of handoff completion signals in a wireless communication environment. System **400** includes a base station **402** that can transmit and/or receive information, signals, data, instructions, commands, bits, symbols, and the like to and/or from one or more access terminals (not shown) (e.g., access terminal **202** of FIG. 2, . . .). Further, base station **402** can transfer and/or obtain information, signals, data, instructions, commands, bits, symbols, and the like to and/or from disparate base station(s), network node(s), and the like.

Base station **402** can include a request evaluator **404**, a resource assigner **406**, and a handoff confirmer **408**. For instance, base station **402** can receive a handoff request signal from an access terminal (not shown) being served by a disparate base station (not shown); thus, base station **402** is in a Non-Serving state with regards to the access terminal that sent the handoff request signal. Request evaluator **404** analyzes the obtained handoff request signal. By way of illustration, request evaluator **404** can determine an identity of the access terminal that sent the handoff request signal based upon such analysis of the handoff request signal. According to a further example, request evaluator **404** can determine resources requested as part of the handoff request signal.

Resource assigner **406** can allocate resources to the access terminal as a function of the handoff request signal. For instance, resource assigner **406** can determine whether to serve the access terminal. Moreover, resource assigner **406** can select resources to allot to the access terminal. By way of illustration, resource assigner **406** assigns non-zero tiles in RLAB, FLAB, etc. Further, resource assigner **406** generates and/or sends a handoff completion signal to the access terminal. The handoff completion signal includes information pertaining to resource allotment yielded by resource assigner **406**. Further, base station **402** (e.g., request evaluator **404**, resource assigner **406**, handoff confirmer **408**, . . .) can send a backhaul message to disparate base station(s) (e.g., source base station, previous serving base station for the access terminal, . . .) that provides notification related to the access terminal handing off to base station **402**. For instance, this backhaul message can be transmitted upon receiving the handoff request signal, determining to serve the access terminal from which the handoff request signal was received, transmitting the handoff completion signal, and/or the like. According to another example, a backhaul message that provides notification related to completion of the handoff can be sent to the disparate base station(s); however, the claimed subject matter is not so limited.

Moreover, handoff confirmer **408** can enable the access terminal to complete handoff such that the access terminal is served by base station **402** and/or determine whether handoff is successfully completed for the access terminal. For instance, upon sending the handoff completion signal, base station **402** can transition to a Confirm Handoff state. While in Confirm Handoff state, handoff confirmer **408** can send a forward link confirmation signal to the access terminal (e.g., transmit a FL packet, ACK to a RL packet, . . .). According to an example, handoff confirmer **408** can monitor the reverse link for a reverse link confirmation signal sent by the access terminal (e.g., a RL packet, an ACK to a FL packet, . . .). Following this example, when handoff confirmer **408** detects the reverse link confirmation signal, base station **402** can be transitioned to a Serving state. Pursuant to another example, handoff confirmer **408** can transition base station **402** to the

Serving state prior to receiving the reverse link confirmation signal from the access terminal (e.g., transition to Serving state upon transmitting the forward link confirmation signal, . . .) since backhaul based procedures can account for error resulting from false detection of handoff at base station **402**. Thus, in accordance with this example, the reverse link confirmation signal may, but need not, be sent by the access terminal (e.g., confirmation at base station **402** can be optional, . . .). Alternatively, base station **402** can obtain a backhaul message while in Confirm Handoff state, and based upon such message, base station **402** can return to Non-Serving state. Moreover, when in Serving state, base station **402** can receive a backhaul message that initiates a transition of base station **402** to Non-Serving state: from Serving state.

According to the depicted example, handoff confirmer **408** can lack a timer. Thus, base station **402** can remain in Confirm Handoff state indefinitely if there is no data activity. However, it is also contemplated that handoff confirmer **408** can include a timer similar to timer **208** utilized in access terminal **202** of FIG. **2**. Hence, pursuant to this example, the timer can begin tracking an amount of elapsed time upon base station **402** transitioning to Confirm Handoff state, and if the amount of elapsed time exceeds a threshold before receiving a reverse link confirmation signal, then base station **402** can be returned to Non-Serving state.

Turning to FIG. **5**, illustrated is an example base station state diagram **500**. For example, state diagram **500** can represent states and transitions between states associated with base station **402** of FIG. **4**. State diagram **500** includes three states: namely, Non-Serving state **502**, Confirm Handoff state **504**, and Serving state **506**. State diagram **500** includes Confirm Handoff state **504** (e.g. a typical Serving state can be split into Confirm Handoff state **504** and Serving state **506**, . . .), which is commonly lacking for conventional techniques.

In Non-Serving state **502**, a base station can receive a handoff request signal from an access terminal desiring to handoff to that particular base station. Further, the base station can allocate resources to the requesting access terminal and/or transmit a handoff completion signal indicating such resource allocation to the requesting access terminal. For instance, the base station can assign non-zero tiles (e.g., non-zero number of resources, . . .) in the handoff completion signal (e.g., RLAB, FLAB, . . .) sent to requesting access terminal. Assignment of a non-zero number of resources to the access terminal enables the terminal to send a full data packet (e.g., reverse link confirmation signal, . . .), which is protected by a full CRC (e.g., 24 bits of CRC, . . .); the full data packet can be used to confirm handoff.

Upon sending the handoff completion signal, the base station can switch from Non-Serving state **502** to Confirm Handoff state **504**. In Confirm Handoff state **504**, the base station can send RLAB/FLAB based on REQ reception or FL data buffer. Further, for Access based handoff, FLAB or RLAB can be sent with non-zero tiles (e.g. non-zero number of resources, . . .) upon entering Confirm Handoff state **504**. Moreover, Confirm Handoff state **504** need not be associated with a timer; thus, the base station can remain in Confirm Handoff state **504** indefinitely if there is no data activity. Further, the base station can receive a backhaul message that causes the base station to transition back to Non-Serving state **502** from Confirm Handoff state **504**. It is to be appreciated, however, that a timer can be utilized to track an amount of time that has passed since the base station entered Confirm Handoff state **504**, and if the amount of time exceeds a threshold prior to transitioning to Serving state **506**, then the base station returns to Non-Serving state **502**.

Moreover, while in Confirm Handoff state **504**, the base station can transmit a forward link confirmation signal that can be used by the requesting access terminal to confirm the handoff. The forward link confirmation signal can be a FL packet, an ACK to a RL packet, and so forth. Further, the base station can monitor the reverse link for a reverse link confirmation signal sent by the requesting access terminal. The reverse link confirmation signal can be a RL packet, an ACK to a FL packet, and the like. If the reverse link confirmation signal is received, then the base station can transition from Confirm Handoff state **504** to Serving state **506**; however, confirmation at the base station can be optional since backhaul based procedures can account for false detection of handoff at the base station.

While in Serving state **506**, the base station can provide connectivity to the access terminal, control power of the access terminal, and the like. Moreover, a backhaul message can be obtained while in Serving state **506**, where the backhaul message causes the base station to switch to Non-Serving state **502** (e.g., the backhaul message can indicate that the access terminal has handed off to a differing base station, . . .). Further, when in Non-Serving state **502**, the base station does not provide connectivity, power control, and so forth for the access terminal.

With reference to FIG. **6**, illustrated is a system **600** that enables compensating for handoff completion signal detection error in a wireless communication environment. System **600** includes access terminal **202**, a source base station **602** and a target base station **604**. Source base station **602** and target base station **604** can each be substantially similar to base station **402** of FIG. **4**. Further, although not shown, it is to be appreciated that system **600** can include substantially any number of access terminals in addition to access terminal **202** and/or substantially any number of base stations in addition to source base station **602** and target base station **604**.

Access terminal **202** can include handoff requester **204** and handoff confirmer **206**, which further comprises timer **208**. Moreover, source base station **602** can include a request evaluator **606**, a resource assigner **608**, and a handoff confirmer **610** and target base station **604** can include a request evaluator **612**, a resource assigner **614** and a handoff confirmer **616**. Request evaluators **606** and **612** can each be substantially similar to request evaluator **404** of FIG. **4**, resource assigners **608** and **614** can each be substantially similar to resource assigner **406** of FIG. **4**, and handoff confirmers **610** and **616** can each be substantially similar to handoff confirmer **408** of FIG. **4**. Although the following describes handoff from source base station **602** to target base station **604**, it is to be appreciated that access terminal **202** can handoff to source base station **602** (e.g., source base station **602** can be a target, . . .) and/or access terminal **202** can handoff from target base station **604** (e.g., target base station **602** can be a source, . . .).

According to an illustration, source base station **602** can serve access terminal **202** during a given time period. For instance, source base station **602** can provide connectivity for access terminal **202**, control power of access terminal **202**, and the like. Thereafter, access terminal **202** can yield a decision to handoff to target base station **604**. Upon generating such handoff decision, handoff requester **204** can generate and send a handoff request signal to target base station **604**, where the handoff request signal can be specific to access terminal **202** (e.g. the handoff request signal can be a function of a unique identifier corresponding to access terminal **202**, the handoff request signal can include information that can be

employed by target base station **604** to distinguish access terminal **202** from disparate access terminal(s) (not shown), . . .). Request evaluator **612** of target base station **604** can review the handoff request signal and determine whether to grant the handoff request. If target base station **604** decides to grant the handoff request, resource assigner **614** can allocate resources to access terminal **202**. Further, resource assigner **614** can yield and/or transmit a handoff completion signal to access terminal **202**. For instance, the handoff completion signal can include a 16 bit CRC; however, the claimed subject matter is not so limited. Upon sending the handoff completion signal, handoff confirmer **616** of target base station **604** can monitor for a reverse link confirmation signal from access terminal **202** and/or transmit a forward link confirmation signal to access terminal **202**. Further, when access terminal **202** obtains the handoff completion signal, handoff confirmer **206** of access terminal **202** can monitor for a forward link confirmation signal from target base station **604** and/or transmit a reverse link confirmation signal to target base station **604**. Moreover, timer **208** can initiate tracking an amount of elapsed time upon receiving the handoff completion signal; thus, if the forward link confirmation signal fails to be received prior to expiration of a threshold amount of time as determined by timer **208**, then handoff confirmer **206** can recognize that handoff to target base station **604** failed. Alternatively, if the forward link confirmation signal is received prior to expiration of the threshold amount of time, then handoff confirmer **206** can determine that the handoff to target base station **604** was successfully completed.

By way of further illustration, source base station **602** and target base station **604** can communicate backhaul messages therebetween (e.g., directly, indirectly through one or more network nodes, . . .). For instance, when handoff confirmer **616** recognizes a successful handoff to target base station **604** (e.g., upon receiving the reverse link confirmation signal, . . .), target base station **604** can transfer a backhaul message to source base station **602** which indicates that access terminal **202** is being served by target base station **604**; thus, source base station **602** can enter Non-Serving state. According to another example, when access terminal **202** fails to obtain a forward link confirmation signal prior to expiration of the threshold amount of time as recognized by timer **208**, access terminal **202** can retry to handoff to target base station **604**, initiate handoff to a disparate base station (not shown), continue to be served by source base station **602**, and so forth. If access terminal **202** continues to be served by source base station **602** (or hands off to a disparate base station), then source base station **602** (or the disparate base station) can send a backhaul message to target base station **604**; this backhaul message can indicate that access terminal **202** is being served by source base station **602** (or the disparate base station). In response to receipt of this backhaul message, target base station **604** can transition from Confirm Handoff state to Non-Serving state.

Aspects of the claimed subject matter enable mitigating the error case where access terminal **202** proceeds as if handoff is complete, while target base station **604** proceeds as if it is non-serving. Accordingly, system **600** utilizes a two-step technique before access terminal **202** can conclude that the handoff is complete. For instance, a probability of false handoff completion signal detection associated with the first step can be of the order 10^{-4} . Further, a probability of false ACK to RL packet detection or false FL packet detection can be of the order 10^{-3} . Thus, the combined probability can be 10^{-7} , which can be an improved rate to enter the error scenario as compared to common techniques.

In contrast, conventional recovery from the false handoff completion signal detection error scenario can be as follows. At the access terminal, the access terminal has RL data, it can send an REQ and get no response, which can result in a data layer failure (e.g., RL supervision failure, . . .). Further, if the access terminal does not have RL data, it can stay in limbo until expiration of a keep alive timer (e.g., the keep alive timer can be 10 seconds, . . .), when the access terminal can generate a RL signaling KeepAlive message (e.g., every 10 seconds, . . .). At the base station, the base station which thinks it is serving can declare supervision failure due to FL/RL packet errors or low Reverse Pilot Channel (R-PICH). Moreover, the other base stations are informed of the supervision failure through backhaul messaging.

Now turning to FIG. 7, illustrated is a system **700** that enables confirming an access grant utilized for transitioning from a semi-connected state in a wireless communication environment. System **700** can employ a similar two-step confirmation technique as described above in conjunction with handing off between base stations. System **700** includes a base station **702** and an access terminal **704**; however, it is to be appreciated that system **700** can include substantially any number of base stations similar to base station **702** and/or substantially any number of access terminals similar to access terminal **704**. Further, system **700** can be a Long Term Evolution (LTE) based system; however, the claimed subject matter is not so limited.

Base station **702** can include a request evaluator **706**, an access grantor **708**, and a state transition confirmer **710**, and access terminal **704** can include a semi-connected exit requester **712** and a state transition confirmer **714**, which can further comprise a timer **716**. Access terminal **704** can employ a semi-connected state in order to save battery life. While in semi-connected state, access terminal **704** can stop being directly power controlled, access terminal **704** can inhibit time tracking and/or time aligning with a network, and access terminal **704** can shut down an associated receiver and transmitter. Further, access terminal **704** can re-enter connected state from semi-connected state without needing to reestablish a context and/or identity of access terminal **704**. For instance, when access terminal **704** transitions to semi-connected state from connected state, base station **702** can maintain a Media Access Control identifier (MAC ID) associated with access terminal **704**. Thus, the MAC ID need not be reassigned upon re-entering connected state from semi-connected state.

In order to quickly transition to connected state from semi-connected state, semi-connected exit requester **712** of access terminal **704** can initiate an exit sequence. For example, semi-connected exit requester **712** can send a signal reserved for access terminal **704** that notifies base station **702** that access terminal **704** desires to reconnect. Each access terminal can be allocated a respective reserved signal to be utilized for re-entry, thus mitigating contention for resources as well as allowing for recovery of access terminal specific context stored by base station **702**.

Semi-connected exit requester **712** transfers the reserved signal pertaining to access terminal **704** to base station **702** for transitioning to connected state from semi-connected state. Request evaluator **706** reviews the reserved signal and determines an identity and/or context associated with access terminal **704** based upon such review. Thereafter, access grantor **708** can reply to the reserved signal by transmitting an access grant, which indicates that base station **702** has recognized, permitted, etc. the request of access terminal **704**. Access terminal **704** can monitor the forward link for the access grant; however, the access grant can be susceptible to false

detection by access terminal **704** (e.g., in a similar manner as compared to false detection of a handoff completion signal as described herein, . . .).

Upon detecting the access grant at access terminal **704**, timer **716** can track an amount of elapsed time and compare this amount of time to a threshold. Further, state transition confirmer **714** of access terminal **704** can monitor the forward link for a forward link confirmation signal sent by state transition confirmer **710** of base station **702** (e.g., access terminal **704** can be in a confirmation state during this time period, . . .). If state transition confirmer **714** detects the forward link confirmation signal prior to expiration of timer **716**, then access terminal **704** can complete the transition to connected state. Alternatively, if state transition confirmer **714** fails to detect the forward link confirmation signal before expiration of timer **716**, then access terminal **704** can return to semi-connected state (e.g., re-entry to connected state can fail under such a scenario, . . .).

Moreover, state transition confirmer **714** of access terminal **704** can transmit a reverse link confirmation signal to base station **702**. After sending the access grant, state transition confirmer **710** of base station **702** can monitor for the reverse link confirmation signal transferred from access terminal **704**. If the reverse link confirmation signal is detected by state transition confirmer **710**, then base station **702** can recognize that access terminal **704** has successfully re-entered connected state. Alternatively, if the reverse link confirmation signal fails to be detected by state transition confirmer **710**, then base station **702** can continue to deal with access terminal **704** as though it is in semi-connected state. Further, although not shown, it is contemplated that state transition confirmer **710** can include a timer similar to timer **716** of access terminal; however, the claimed subject matter is not so limited.

Referring to FIGS. **8-9**, methodologies relating to mitigating error due to false completion signal detection in a wireless communication environment are illustrated. While, for purposes of simplicity of explanation, the methodologies are shown and described as a series of acts, it is to be understood and appreciated that the methodologies are not limited by the order of acts, as some acts can, in accordance with one or more embodiments, occur in different orders and/or concurrently with other acts from that shown and described herein. For example, those skilled in the art will understand and appreciate that a methodology could alternatively be represented as a series of interrelated states or events, such as in a state diagram. Moreover, not all illustrated acts can be required to implement a methodology in accordance with one or more embodiments.

With reference to FIG. **8**, illustrated is a methodology **800** that facilitates mitigating error associated with false detection of completion signals in a wireless communication environment. At **802**, an access terminal specific request signal can be transmitted to a target base station. For example, the request signal can be a handoff request signal. Following this example, a decision can be made to handoff from a source base station to the target base station and the access terminal can switch to a Try to Handoff state; the handoff request signal can be sent to the target base station while in Try to Handoff state. According to another illustration, the request signal can be a reserved signal utilized by the access terminal to re-enter a connected state from a semi-connected state. Further, the request signal can include information pertaining to an identity of the access terminal, which can enable the target base station to discern the identity of the access terminal based upon an analysis of the request signal. By way of further illustration, the access terminal specific request signal

can be transmitted with non-zero buffer size even if a buffer associated with an access terminal is empty when request (REQ) based handoff is utilized. At **804**, a completion signal in response to the request signal can be detected. The completion signal, for instance, can be a handoff completion signal. Examples of handoff completion signals include a reverse link assignment block (RLAB), a forward link assignment block (FLAB), an AccessGrant, or the like. Moreover, in the context of semi-connected exit, the completion signal can be an AccessGrant.

At **806**, a timer can be started upon detecting the completion signal. Further, the access terminal can transition to a confirmation state (e.g., Confirm Handoff state, Confirm Reentry state, . . .) when the completion signal is detected. At **808**, transmission of the completion signal from the target base station can be confirmed by determining whether a forward link confirmation signal is received from the target base station prior to expiration of the timer. The timer can expire at a threshold time duration (e.g., 50 ms, . . .), where the threshold time duration can be preset, dynamically allocated, and so forth. The forward link confirmation signal can indicate that handoff to the target base station has been successful or re-entry to connected state from semi-connected state has been successful. Moreover, a reverse link confirmation signal can be transmitted to the target base station to enable the target base station to recognize that handoff has successfully been completed or the access terminal has successfully re-entered connected state from semi-connected state. The forward link confirmation signal can be a forward link packet or an acknowledgement to a reverse link packet, while the reverse link confirmation signal can be a reverse link packet or an acknowledgement to a forward link packet; as such, the forward link confirmation signal and the reverse link confirmation signal can include more cyclic redundancy check (CRC) bits (e.g., 24 bits of CRC for the confirmation signals, . . .) as compared to the completion signal (e.g., 16 bits of CRC for the completion signal, . . .).

Pursuant to another example, the access terminal can return to a Try to Handoff state upon determining that the timer expired prior to receipt of the forward link confirmation signal. Further, when the forward link confirmation signal is not received, reconfirmation can be performed. For instance, if handoff was initiated by transmitting access probes, then access probes can be transmitted again when effectuating reconfirmation. Moreover, if handoff was initiated by transmitting either a channel quality indicator (CQI) signal or a request (REQ) signal, then a CQI signal or a REQ signal can continue to be transmitted when performing reconfirmation.

Now turning to FIG. **9**, illustrated is a methodology **900** that facilitates recovering from false completion signal detection in a wireless communication environment. At **902**, an access terminal specific request signal can be received from an access terminal. The request signal can be handoff request signal or a reserved signal used by the access terminal for exiting semi-connected state. Further, the request signal can be analyzed to determine an identity of the access terminal, a context associated with the access terminal, or the like. By way of illustration, the request signal can be obtained while a base station is in Non-Serving state; however, the claimed subject matter is not so limited. At **904**, a completion signal can be transmitted to the access terminal in response to the request signal. The completion signal, for instance, can indicate resources assigned to the access terminal. For example, non-zero amounts of resources (e.g., non-zero tiles, . . .) can be allocated in the completion signal. Further, upon sending the completion signal, the base station can transition to a confirmation state (e.g., Confirm Handoff state, Confirm Re-

entry state, . . .). The completion signal, for instance, can be a handoff completion signal. Examples of handoff completion signals include a reverse link assignment block (RLAB), a forward link assignment block (FLAB), an AccessGrant, and so forth. Moreover, in the context of semi-connected exit, the completion signal can be an AccessGrant. According to another illustration, the completion signal can be transmitted to the access terminal irrespective of buffer data included in the request signal.

At **906**, a forward link confirmation signal can be transmitted to the access terminal. The forward link confirmation signal can enable the access terminal to confirm receipt of the completion signal. Based upon this confirmation, the access terminal can transition to Handoff Complete state or connected state. For example, the forward link confirmation signal can be a forward link assignment block (FLAB), an acknowledgement (ACK) to a reverse link packet, and so forth. Moreover, a reverse link confirmation signal can be received from the access terminal; upon obtaining the reverse link confirmation signal, the base station can recognize that the access terminal is being served by the base station (under the handoff scenario) (e.g., the base station can transition to Serving state, . . .) or the access terminal has returned to connected state (under the semi-connected exit scenario).

Further, backhaul messages can be received that can be utilized to vary base station state. For instance, when in Serving state, a backhaul message can be obtained that notifies the base station that a disparate base station is serving the access terminal; thus, the base station can switch to Non-Serving state. By way of further illustration, when in Confirm Handoff state a backhaul message can be received that indicates to the base station that a disparate base station is serving the access terminal, and hence, the base station can transition to Non-Serving state.

It will be appreciated that, in accordance with one or more aspects described herein, inferences can be made regarding recovering from false detection of completion signals. As used herein, the term to “infer” or “inference” refers generally to the process of reasoning about or inferring states of the system, environment, and/or user from a set of observations as captured via events and/or data. Inference can be employed to identify a specific context or action, or can generate a probability distribution over states, for example. The inference can be probabilistic that is, the computation of a probability distribution over states of interest based on a consideration of data and events. Inference can also refer to techniques employed for composing higher-level events from a set of events and/or data. Such inference results in the construction of new events or actions from a set of observed events and/or stored event data, whether or not the events are correlated in close temporal proximity, and whether the events and data come from one or several event and data sources.

According to an example, one or methods presented above can include making inferences pertaining to determining an identity of an access terminal based upon information included in an access terminal specific request signal. By way of further illustration, an inference can be made related to determining an amount of resources to allocate to an access terminal that can be indicated as part of a completion signal sent to the access terminal. It will be appreciated that the foregoing examples are illustrative in nature and are not intended to limit the number of inferences that can be made or the manner in which such inferences are made in conjunction with the various embodiments and/or methods described herein.

FIG. **10** is an illustration of an access terminal **1000** that recovers from erroneous completion signal detection in a wireless communication system. Access terminal **1000** comprises a receiver **1002** that receives a signal from, for instance, a receive antenna (not shown), and performs typical actions thereon (e.g., filters, amplifies, downconverts, etc.) the received signal and digitizes the conditioned signal to obtain samples. Receiver **1002** can be, for example, an MMSE receiver, and can comprise a demodulator **1004** that can demodulate received symbols and provide them to a processor **1006** for channel estimation. Processor **1006** can be a processor dedicated to analyzing information received by receiver **1002** and/or generating information for transmission by a transmitter **1016**, a processor that controls one or more components of access terminal **1000**, and/or a processor that both analyzes information received by receiver **1002**, generates information for transmission by transmitter **1016**, and controls one or more components of access terminal **1000**.

Access terminal **1000** can additionally comprise memory **1008** that is operatively coupled to processor **1006** and that can store data to be transmitted, received data, and any other suitable information related to performing the various actions and functions set forth herein. Memory **1008**, for instance, can store protocols and/or algorithms associated with confirming handoff or semi-connected exit completion.

It will be appreciated that the data store (e.g., memory **1008**) described herein can be either volatile memory or nonvolatile memory, or can include both volatile and nonvolatile memory. By way of illustration, and not limitation, nonvolatile memory can include read only memory (ROM), programmable ROM (PROM), electrically programmable ROM (EPROM), electrically erasable PROM (EEPROM), or flash memory. Volatile memory can include random access memory (RAM), which acts as external cache memory. By way of illustration and not limitation, RAM is available in many forms such as synchronous RAM (SRAM), dynamic RAM (DRAM), synchronous DRAM (SDRAM), double data rate SDRAM (DDR SDRAM), enhanced SDRAM (ESDRAM), Synchlink DRAM (SLDRAM), and direct Rambus RAM (DRRAM). The memory **1008** of the subject systems and methods is intended to comprise, without being limited to, these and any other suitable types of memory.

Receiver **1002** is further operatively coupled to a requester **1010** and/or a completion confirmer **1012**. Requester **1010** can be substantially similar to handoff requester **204** of FIG. **2** and/or semi-connected exit requester **712** of FIG. **7**. Moreover, completion confirmer **1012** can be substantially similar to handoff confirmer **206** of FIG. **2** and/or state transition confirmer **714** of FIG. **7**. Requester **1010** can generate and/or transmit a request signal (e.g., handoff request signal, reserved signal, . . .) uniquely associated with access terminal **1000**. For example, the request signal can include information pertaining to an identifier of access terminal **1000**. Requester **1010** can send the request signal to effectuate handoff to a target base station and/or re-entry to connected state from semi-connected state. In response to the transmitted request signal, access terminal **1000** can detect (e.g., falsely, appropriately, . . .) a completion signal (e.g., handoff completion signal, . . .). To account for false detection of the completion signal, completion confirmer **1012** can monitor for a forward link confirmation signal from the target base station. Moreover, completion confirmer **1012** can transmit a reverse link confirmation signal to the target base station, which can be used by the target base station to verify success of the handoff or re-entry to connected state. Access terminal **1000** still further comprises a modulator **1014** and a transmitter **1016** that transmits the signal to, for instance, a base station,

another access terminal, etc. Although depicted as being separate from the processor **1006**, it is to be appreciated that requester **1010**, completion confirmer **1012** and/or modulator **1014** can be part of processor **1006** or a number of processors (not shown).

FIG. **11** is an illustration of a system **1100** that facilitates mitigating false detection of completion signals in a wireless communication environment. System **1100** comprises a base station **1102** (e.g., access point, . . .) with a receiver **1110** that receives signal(s) from one or more access terminals **1104** through a plurality of receive antennas **1106**, and a transmitter **1124** that transmits to the one or more access terminals **1104** through a transmit antenna **1108**. Receiver **1110** can receive information from receive antennas **1106** and is operatively associated with a demodulator **1112** that demodulates received information. Demodulated symbols are analyzed by a processor **1114** that can be similar to the processor described above with regard to FIG. **10**, and which is coupled to a memory **1116** that stores data to be transmitted to or received from access terminal(s) **1104** (or a disparate base station (not shown)) and/or any other suitable information related to performing the various actions and functions set forth herein. Processor **1114** is further coupled to a resource assigner **1118** that allocates resources to access terminal(s) **1104** in response to respective, received request signal(s). Resource assigner **1118** can be operatively coupled to a completion confirmer **1120** that monitors for reverse link confirmation signals and/or generates forward link confirmation signals as described herein. It is contemplated that resource assigner **1118** can be substantially similar to resource assigner **406** of FIG. **4** and/or access grantor **708** of FIG. **7** and/or completion confirmer **1120** can be substantially similar to handoff confirmer **408** of FIG. **4** and/or state transition confirmer **710** of FIG. **7**. Further, resource assigner **1118** and/or completion confirmer **1120** can provide information to be transmitted to a modulator **1122**. Modulator **1122** can multiplex a frame for transmission by a transmitter **1124** through antennas **1108** to access terminal(s) **1104**. Although depicted as being separate from the processor **1114**, it is to be appreciated that resource assigner **1118**, completion confirmer **1120** and/or modulator **1122** can be part of processor **1114** or a number of processors (not shown).

FIG. **12** shows an example wireless communication system **1200**. The wireless communication system **1200** depicts one base station **1210** and one access terminal **1250** for sake of brevity. However, it is to be appreciated that system **1200** can include more than one base station and/or more than one access terminal, wherein additional base stations and/or access terminals can be substantially similar or different from example base station **1210** and access terminal **1250** described below. In addition, it is to be appreciated that base station **1210** and/or access terminal **1250** can employ the systems (FIGS. **1-2**, **4**, **6-7**, **10-11**, and **13-14**) and/or methods (FIGS. **8-9**) described herein to facilitate wireless communication there between.

At base station **1210**, traffic data for a number of data streams is provided from a data source **1212** to a transmit (TX) data processor **1214**. According to an example, each data stream can be transmitted over a respective antenna. TX data processor **1214** formats, codes, and interleaves the traffic data stream based on a particular coding scheme selected for that data stream to provide coded data.

The coded data for each data stream can be multiplexed with pilot data using orthogonal frequency division multiplexing (OFDM) techniques. Additionally or alternatively, the pilot symbols can be frequency division multiplexed (FDM), time division multiplexed (TDM), or code division

multiplexed (CDM). The pilot data is typically a known data pattern that is processed in a known manner and can be used at access terminal **1250** to estimate channel response. The multiplexed pilot and coded data for each data stream can be modulated (e.g., symbol mapped) based on a particular modulation scheme (e.g., binary phase-shift keying (BPSK), quadrature phase-shift keying (QPSK), M-phase-shift keying (M-PSK), M-quadrature amplitude modulation (M-QAM), etc.) selected for that data stream to provide modulation symbols. The data rate, coding, and modulation for each data stream can be determined by instructions performed or provided by processor **1230**.

The modulation symbols for the data streams can be provided to a TX MIMO processor **1220**, which can further process the modulation symbols (e.g. for OFDM). TX MIMO processor **1220** then provides N_T modulation symbol streams to N_T transmitters (TMTR) **1222a** through **1222t**. In various embodiments, TX MIMO processor **1220** applies beamforming weights to the symbols of the data streams and to the antenna from which the symbol is being transmitted.

Each transmitter **1222** receives and processes a respective symbol stream to provide one or more analog signals, and further conditions (e.g., amplifies, filters, and upconverts) the analog signals to provide a modulated signal suitable for transmission over the MIMO channel. Further, N_T modulated signals from transmitters **1222a** through **1222t** are transmitted from N_T antennas **1224a** through **1224t**, respectively.

At access terminal **1250**, the transmitted modulated signals are received by N_R antennas **1252a** through **1252r** and the received signal from each antenna **1252** is provided to a respective receiver (RCVR) **1254a** through **1254r**. Each receiver **1254** conditions (e.g., filters, amplifies, and downconverts) a respective signal, digitizes the conditioned signal to provide samples, and further processes the samples to provide a corresponding “received” symbol stream.

An RX data processor **1260** can receive and process the N_R received symbol streams from N_R receivers **1254** based on a particular receiver processing technique to provide N_T “detected” symbol streams. RX data processor **1260** can demodulate, deinterleave, and decode each detected symbol stream to recover the traffic data for the data stream. The processing by RX data processor **1260** is complementary to that performed by TX MIMO processor **1220** and TX data processor **1214** at base station **1210**.

A processor **1270** can periodically determine which available technology to utilize as discussed above. Further, processor **1270** can formulate a reverse link message comprising a matrix index portion and a rank value portion.

The reverse link message can comprise various types of information regarding the communication link and/or the received data stream. The reverse link message can be processed by a TX data processor **1238**, which also receives traffic data for a number of data streams from a data source **1236**, modulated by a modulator **1280**, conditioned by transmitters **1254a** through **1254r**, and transmitted back to base station **1210**.

At base station **1210**, the modulated signals from access terminal **1250** are received by antennas **1224**, conditioned by receivers **1222**, demodulated by a demodulator **1240**, and processed by a RX data processor **1242** to extract the reverse link message transmitted by access terminal **1250**. Further, processor **1230** can process the extracted message to determine which precoding matrix to use for determining the beamforming weights.

Processors **1230** and **1270** can direct (e.g., control, coordinate, manage, etc.) operation at base station **1210** and access terminal **1250**, respectively. Respective processors **1230** and

1270 can be associated with memory 1232 and 1272 that store program codes and data. Processors 1230 and 1270 can also perform computations to derive frequency and impulse response estimates for the uplink and downlink, respectively.

In an aspect, logical channels are classified into Control Channels and Traffic Channels. Logical Control Channels can include a Broadcast Control Channel (BCCH), which is a DL channel for broadcasting system control information. Further, Logical Control Channels can include a Paging Control Channel (PCCH), which is a DL channel that transfers paging information. Moreover, the Logical Control Channels can comprise a Multicast Control Channel (MCCH), which is a Point-to-multipoint DL channel used for transmitting Multimedia Broadcast and Multicast Service (MBMS) scheduling and control information for one or several MTCHs. Generally, after establishing a Radio Resource Control (RRC) connection, this channel is only used by UEs that receive MBMS (e.g., old MCCH+MSCH). Additionally, the Logical Control Channels can include a Dedicated Control Channel (DCCH), which is a Point-to-point bi-directional channel that transmits dedicated control information and can be used by UEs having a RRC connection. In an aspect, the Logical Traffic Channels can comprise a Dedicated Traffic Channel (DTCH), which is a Point-to-point bi-directional channel dedicated to one UE for the transfer of user information. Also, the Logical Traffic Channels can include a Multicast Traffic Channel (MTCH) for Point-to-multipoint DL channel for transmitting traffic data.

In an aspect, Transport Channels are classified into DL and UL. DL Transport Channels comprise a Broadcast Channel (BCH), a Downlink Shared Data Channel (DL-SDCH) and a Paging Channel (PCH). The PCH can support UE power saving (e.g., Discontinuous Reception (DRX) cycle can be indicated by the network to the UE, . . .) by being broadcasted over an entire cell and being mapped to Physical layer (PHY) resources that can be used for other control/traffic channels. The UL Transport Channels can comprise a Random Access Channel (RACH), a Request Channel (REQCH), a Uplink Shared Data Channel (UL-SDCH) and a plurality of PHY channels.

The PHY channels can include a set of DL channels and UL channels. For example, the DL PHY channels can include: Common Pilot Channel (CPICH); Synchronization Channel (SCH); Common Control Channel (CCCH); Shared DL Control Channel (SDCCH); Multicast Control Channel (MCCH); Shared UL Assignment Channel (SUACH); Acknowledgement Channel (ACKCH); DL Physical Shared Data Channel (DL-PSDCH); UL Power Control Channel (UPCCH); Paging Indicator Channel (PICH); and/or Load Indicator Channel (LICH). By way of further illustration, the UL PHY Channels can include: Physical Random Access Channel (PRACH); Channel Quality Indicator Channel (CQICH); Acknowledgement Channel (ACKCH); Antenna Subset Indicator Channel (ASICH); Shared Request Channel (SREQCH); UL Physical Shared Data Channel (UL-PSDCH); and/or Broadband Pilot Channel (BPICH).

It is to be understood that the embodiments described herein can be implemented in hardware, software, firmware, middleware, microcode, or any combination thereof. For a hardware implementation, the processing units can be implemented within one or more application specific integrated circuits (ASICs), digital signal processors (DSPs), digital signal processing devices (DSPDs), programmable logic devices (PLDs), field programmable gate arrays (FPGAs), processors, controllers, micro-controllers, microprocessors, other electronic units designed to perform the functions described herein, or a combination thereof.

When the embodiments are implemented in software, firmware, middleware or microcode, program code or code segments, they can be stored in a machine-readable medium, such as a storage component. A code segment can represent a procedure, a function, a subprogram, a program, a routine, a subroutine, a module, a software package, a class, or any combination of instructions, data structures, or program statements. A code segment can be coupled to another code segment or a hardware circuit by passing and/or receiving information, data, arguments, parameters, or memory contents. Information, arguments, parameters, data, etc. can be passed, forwarded, or transmitted using any suitable means including memory sharing, message passing, token passing, network transmission, etc.

For a software implementation, the techniques described herein can be implemented with modules (e.g., procedures, functions, and so on) that perform the functions described herein. The software codes can be stored in memory units and executed by processors. The memory unit can be implemented within the processor or external to the processor, in which case it can be communicatively coupled to the processor via various means as is known in the art.

With reference to FIG. 13, illustrated is a system 1300 that enables utilizing an error recovery scheme in a wireless communication environment. For example, system 1300 can reside within an access terminal. It is to be appreciated that system 1300 is represented as including functional blocks, which can be functional blocks that represent functions implemented by a processor, software, or combination thereof (e.g., firmware). System 1300 includes a logical grouping 1302 of electrical components that can act in conjunction. For instance, logical grouping 1302 can include an electrical component for transferring an access terminal specific request signal to a target base station 1304. The request signal, for example, can be utilized for handing off, transitioning from semi-connected state, and so forth. Further, logical grouping 1302 can include an electrical component for initiating a timer when a completion signal is detected 1306. Moreover, logical grouping 1302 can comprise an electrical component for confirming transmission of the completion signal from the target base station by determining whether a forward link confirmation signal is obtained before expiration of the timer 1308. Additionally, system 1300 can include a memory 1310 that retains instructions for executing functions associated with electrical components 1304, 1306, and 1308. While shown as being external to memory 1310, it is to be understood that one or more of electrical components 1304, 1306, and 1308 can exist within memory 1310.

Turning to FIG. 14, illustrated is a system 1400 that enables mitigating error associated with false completion signal detection in a wireless communication environment. System 1400 can reside at least partially within a base station, for instance. As depicted, system 1400 includes functional blocks that can represent functions implemented by a processor, software, or combination thereof (e.g., firmware). System 1400 includes a logical grouping 1402 of electrical components that can act in conjunction. Logical grouping 1402 can include an electrical component for analyzing an obtained request signal specific to an access terminal 1404. Further, logical grouping 1402 can include an electrical component for sending a completion signal to the access terminal based upon the request signal 1406. The completion signal, for instance, can indicate a resource allotment for the access terminal. Moreover, logical grouping 1402 can include an electrical component for transmitting a forward link confirmation signal to the access terminal that allows the access terminal to confirm receipt of the completion signal 1408.

25

Additionally, system **1400** can include a memory **1410** that retains instructions for executing functions associated with electrical components **1404**, **1406**, and **1408**. While shown as being external to memory **1410**, it is to be understood that electrical components **1404**, **1406**, and **1408** can exist within memory **1410**.

What has been described above includes examples of one or more embodiments. It is, of course, not possible to describe every conceivable combination of components or methodologies for purposes of describing the aforementioned embodiments, but one of ordinary skill in the art may recognize that many further combinations and permutations of various embodiments are possible. Accordingly, the described embodiments are intended to embrace all such alterations, modifications and variations that fall within the spirit and scope of the appended claims. Furthermore, to the extent that the term “includes” is used in either the detailed description or the claims, such term is intended to be inclusive in a manner similar to the term “comprising” as “comprising” is interpreted when employed as a transitional word in a claim.

What is claimed is:

1. A method at an access terminal that facilitates mitigating error associated with false detection of completion signals in a wireless communication environment, comprising:

transmitting an access terminal specific request signal to a target base station;

detecting a completion signal in response to the access terminal specific request signal, wherein the completion signal is one of a reverse link assignment block, a forward link assignment block, or an access grant;

starting a timer upon detecting the completion signal; and confirming transmission of the completion signal from the target base station by determining whether a forward link confirmation signal is received from the target base station prior to an expiration of the timer.

2. The method of claim **1**, wherein the access terminal specific request signal is a handoff request signal.

3. The method of claim **2**, further comprising: deciding to handoff from a source base station to the target base station; and

transmitting the handoff request signal while in a Try to Handoff state.

4. The method of claim **1**, wherein the access terminal specific request signal is a reserved signal utilized to re-enter a connected state from a semi-connected state.

5. The method of claim **4**, wherein the completion signal is the access grant.

6. The method of claim **1**, wherein the access terminal specific request signal includes information pertaining to an identity of the access terminal.

7. The method of claim **1**, further comprising transmitting the access terminal specific request signal with a non-zero buffer size even if a buffer associated with the access terminal is empty when request (REQ) based handoff is utilized.

8. The method of claim **1**, further comprising transitioning to a confirmation state when the completion signal is detected.

9. The method of claim **1**, further comprising returning to a Try to Handoff state upon determining that the timer expired prior to receipt of the forward link confirmation signal.

10. The method of claim **9**, further comprising performing reconfirmation when the forward link confirmation signal is not received by transmitting access probes again if handoff was initiated by transmitting access probes or, if handoff was initiated by transmitting either a channel quality indicator

26

(CQI) signal or a request (REQ) signal, continuing to transmit the CQI signal or the REQ signal until confirmation is attained.

11. The method of claim **1**, wherein the timer expires at a threshold time duration.

12. The method of claim **1**, wherein the forward link confirmation signal is one of a forward link packet or an acknowledgement to a reverse link packet.

13. The method of claim **1**, further comprising transmitting a reverse link confirmation signal to the target base station to enable the target base station to recognize at least one of handoff to the target base station has been successful or reentry to connected state from a semi-connected state has been successful.

14. The method of claim **13**, wherein the reverse link confirmation signal is one of a reverse link packet or an acknowledgement to a forward link packet.

15. The method of claim **13**, wherein the forward link confirmation signal and the reverse link confirmation signal each include more cyclic redundancy check (CRC) bits than the completion signal.

16. An access terminal, comprising:

a memory that retains instructions related to sending an access terminal specific request signal to a target base station, receiving a completion signal in response to the access terminal specific request signal, wherein the completion signal is one of a reverse link assignment block, a forward link assignment block, or an access grant, initiating a timer upon receiving the completion signal, and confirming transmission of the completion signal from the target base station by identifying whether a forward link confirmation signal is obtained from the target base station prior to an expiration of the timer; and

a processor, coupled to the memory, configured to execute the instructions retained in the memory.

17. The access terminal of claim **16**, wherein the access terminal specific request signal is a handoff request signal.

18. The access terminal of claim **16**, wherein the access terminal specific request signal is a reserved signal utilized to re-enter a connected state from a semi-connected state.

19. The access terminal of claim **18**, wherein the completion signal is the access grant.

20. The access terminal of claim **16**, wherein the access terminal specific request signal includes information pertaining to an identity of the access terminal.

21. The access terminal of claim **16**, wherein the memory further retains instructions related to sending the access terminal specific request signal with a non-zero buffer size even if a buffer associated with the access terminal is empty when a request (REQ) based handoff is employed.

22. The access terminal of claim **16**, wherein the memory further retains instructions related to switching to a confirmation state when the completion signal is received.

23. The access terminal of claim **16**, wherein the memory further retains instructions related to switching to a Try to Handoff state upon determining that the timer expired before obtaining the forward link confirmation signal.

24. The access terminal of claim **23**, wherein the memory further retains instructions related to effectuating reconfirmation when the forward link confirmation signal is not received by sending access probes again if handoff was initiated by sending access probes or, if handoff was initiated by sending either a channel quality indicator (CQI) signal or a request (REQ) signal, continuing to send the CQI signal to the REQ signal until confirmation is attained.

27

25. The access terminal of claim 16, wherein the timer expires at a threshold time duration.

26. The access terminal of claim 16, wherein the forward link confirmation signal is one of a forward link packet or an acknowledgement to a reverse link packet.

27. The access terminal of claim 16, wherein the memory further retains instructions related to sending a reverse link confirmation signal to the target base station to enable the target base station to recognize at least one of handoff to the target base station has been successful or re-entry to connected state from semi-connected state has been successful.

28. The access terminal of claim 27, wherein the reverse link confirmation signal is one of a reverse link packet or an acknowledgement to a forward link packet.

29. The access terminal of claim 27, wherein the forward link confirmation signal and the reverse link confirmation signal each include more cyclic redundancy check (CRC) bits than the completion signal.

30. An access terminal that enables utilizing an error recovery scheme in a wireless communication environment, comprising:

means for transferring an access terminal specific request signal to a target base station;

means for initiating a timer when a completion signal is detected, wherein the completion signal is one of a reverse link assignment block, a forward link assignment block, or an access grant; and

means for confirming transmission of the completion signal from the target base station by determining whether a forward link confirmation signal is obtained before an expiration of the timer.

31. The access terminal of claim 30, further comprising means for transferring the access terminal specific request signal to the target base station to effectuate a handoff from a source base station to the target base station.

32. The access terminal of claim 31, wherein the access terminal specific request signal is a handoff request signal.

33. The access terminal of claim 32, wherein the handoff request signal has a non-zero buffer even if a buffer associated with the access terminal is empty when a request (REQ) based handoff is effectuated.

34. The access terminal of claim 30, further comprising means for transferring the access terminal specific request signal to the target base station to effectuate transitioning from a semi-connected state to a connected state.

35. The access terminal of claim 34, wherein the access terminal specific request signal is a reserved signal and the completion signal is the access grant.

36. The access terminal of claim 30, wherein the timer expires at a threshold time duration that is one of preset or dynamically determined.

37. The access terminal of claim 36, further comprising means for switching to a Try to Handoff state if the forward link confirmation signal is not obtained within the threshold time duration.

38. The access terminal of claim 30, further comprising means for performing reconfirmation when the forward link confirmation signal is not obtained.

39. The access terminal of claim 30, further comprising means for transferring a reverse link confirmation signal to the target base station to enable the target base station to recognize at least one of handoff to the target base station has been successful or re-entry to connected state from semi-connected state has been successful.

28

40. The access terminal of claim 39, wherein the forward link confirmation signal and the reverse link confirmation signal each include more cyclic redundancy check (CRC) bits than the completion signal.

41. A computer program product, comprising:

a non-transitory computer-readable medium comprising:
code for transferring an access terminal specific request signal by an access terminal to a target base station;
code for initiating a timer at the access terminal when a completion signal is detected, wherein the completion signal is one of a reverse link assignment block, a forward link assignment block, or an access grant; and
code for confirming transmission of the completion signal from the target base station at the access terminal by determining whether a forward link confirmation signal is obtained by the access terminal before an expiration of the timer.

42. The computer program product of claim 41, wherein the computer-readable medium further comprises code for transferring the access terminal specific request signal to the target base station to effectuate a handoff from a source base station to the target base station.

43. The computer program product of claim 41, wherein the computer-readable medium further comprises code for transferring the access terminal specific request signal to the target base station to effectuate transitioning from a semi-connected state to a connected state.

44. The computer program product of claim 41, wherein the computer-readable medium further comprises code for returning to a Try to Handoff state upon determining that the timer expired before obtaining the forward link confirmation signal.

45. The computer program product of claim 41, wherein the timer expires at a threshold time duration that is one of preset or dynamically determined.

46. The computer program product of claim 41, wherein the computer-readable medium further comprises code for transferring a reverse link confirmation signal to the target base station to enable the target base station to recognize at least one of handoff to the target base station has been successful or re-entry to a connected state from a semi-connected state has been successful.

47. The computer program product of claim 46, wherein the forward link confirmation signal and the reverse link confirmation signal each include more cyclic redundancy check (CRC) bits than the completion signal.

48. In a wireless communications system, an access terminal comprising: a processor configured to:

transmit an access terminal specific request signal to a target base station;

detect a completion signal in response to the access terminal specific request signal, wherein the completion signal is one of a reverse link assignment block, a forward link assignment block, or an access grant;

start a timer upon detecting the completion signal; and
confirm transmission of the completion signal from the target base station by determining whether a forward link confirmation signal is received from the target base station prior to an expiration of the timer.

49. A method at a base station that facilitates recovering from false completion signal detection in a wireless communication environment, comprising:

receiving an access terminal specific request signal from an access terminal;

transmitting a completion signal to the access terminal in response to the access terminal specific request signal, the completion signal indicates resources assigned to the

access terminal, wherein the completion signal is one of a reverse link assignment block, a forward link assignment block, or an access grant; and

transmitting a forward link confirmation signal to the access terminal, wherein the forward link confirmation signal enables the access terminal to confirm receipt of the completion signal prior to expiration of a timer of the access terminal.

50. The method of claim **49**, wherein the access terminal specific request signal is one of a handoff request signal or a reserved signal utilized by the access terminal to exit semi-connected state.

51. The method of claim **49**, further comprising analyzing the access terminal specific request signal to determine at least one of an identity of the access terminal or a context associated with the access terminal.

52. The method of claim **49**, further comprising allocating non-zero amounts of resources to the access terminal.

53. The method of claim **49**, further comprising transitioning to a confirmation state upon transmitting the completion signal to the access terminal.

54. The method of claim **49**, wherein the forward link confirmation signal is one of a forward link assignment block or an acknowledgement (ACK) to a reverse link packet.

55. The method of claim **49**, further comprising transmitting the completion signal to the access terminal irrespective of buffer data being included in the access terminal specific request signal.

56. The method of claim **49**, further comprising:
receiving a reverse link confirmation signal from the access terminal; and
recognizing at least one of handoff for the access terminal has completed or the access terminal has returned to connected state from semi-connected state upon receiving the reverse link confirmation signal.

57. The method of claim **49**, further comprising:
receiving a backhaul message that indicates a disparate base station serves the access terminal; and
transitioning to a Non-Serving state from at least one of a Serving state or a Confirm Handoff state upon receiving the backhaul message.

58. A wireless communications base station, comprising:
a memory that retains instructions related to obtaining an access terminal specific request signal from an access terminal, sending a completion signal to the access terminal in response to the access terminal specific request signal, the completion signal is one of a reverse link assignment block, a forward link assignment block, or an access grant, and sending a forward link confirmation signal to the access terminal, wherein the forward link confirmation signal enables the access terminal to confirm receipt of the completion signal prior to expiration of a timer of the access terminal; and
a processor, coupled to the memory, configured to execute the instructions retained in the memory.

59. The wireless communications base station of claim **58**, wherein the access terminal specific request signal is one of a handoff request signal or a reserved signal utilized by the access terminal to exit semi-connected state.

60. The wireless communications base station of claim **58**, wherein the memory further retains instructions related to analyzing the access terminal specific request signal to determine at least one of an identity of the access terminal or a context associated with the access terminal.

61. The wireless communications base station of claim **58**, wherein the memory further retains instruction related to

transitioning to a confirmation state upon transmitting the completion signal to the access terminal.

62. The wireless communications base station of claim **58**, wherein the forward link confirmation signal is one of a forward link assignment block or an acknowledgement (ACK) to a reverse link packet.

63. The wireless communications base station of claim **58**, wherein the memory further retains instructions related to sending the completion signal to the access terminal irrespective of buffer data being included in the access terminal specific request signal.

64. The wireless communications base station of claim **58**, wherein the memory further retains instruction related to recognizing at least one of handoff for the access terminal has completed or the access terminal has returned to a connected state from a semi-connected state upon detecting a reverse link confirmation signal.

65. The wireless communications base station of claim **58**, wherein the memory further retains instruction related to transitioning to a Non-Serving state from at least one of a Serving state or a Confirm Handoff state upon receiving a backhaul message that indicates a disparate base station serves the access terminal.

66. A wireless communications base station that enables mitigating error associated with false completion signal detection in a wireless communication environment, comprising:

means for analyzing an obtained request signal specific to an access terminal;

means for sending a completion signal to the access terminal based upon the request signal specific to the access terminal, wherein the completion signal is one of a reverse link assignment block, a forward link assignment block, or an access grant; and

means for transmitting a forward link confirmation signal to the access terminal that allows the access terminal to confirm receipt of the completion signal prior to expiration of a timer of the access terminal.

67. The wireless communications base station of claim **66**, wherein the request signal to the access terminal is one of a handoff request signal or a reserved signal utilized by the access terminal to exit semi-connected state.

68. The wireless communications base station of claim **66**, further comprising means for determining at least one of an identity of the access terminal or a context corresponding to the access terminal based upon analyzing the request signal specific to the access terminal.

69. The wireless communications base station of claim **66**, further comprising means for transitioning to a confirmation state upon sending the completion signal to the access terminal.

70. The wireless communications base station of claim **66**, wherein the forward link confirmation signal is one of a forward link assignment block or an acknowledgement (ACK) to a reverse link packet.

71. The wireless communications base station of claim **66**, further comprising means for sending the completion signal to the access terminal irrespective of buffer data being included in the request signal specific to the access terminal.

72. The wireless communications base station of claim **66**, further comprising means for recognizing at least one of handoff for the access terminal has completed or the access terminal has returned to connected state from semi-connected state upon detecting a reverse link confirmation signal from the access terminal.

73. The wireless communications base station of claim **66**, further comprising means for switching to a Non-Serving

state from at least one of a Serving state or a Confirm Handoff state upon receiving a backhaul message that indicates a disparate base station serves the access terminal.

74. A computer program product, comprising: a non-transitory computer-readable medium comprising:

code for evaluating an obtained request signal specific to an access terminal by a target base station;

code for transferring a completion signal to the access terminal by the target base station based upon the request signal specific to the access terminal, the completion signal is one of a reverse link assignment block, a forward link assignment block, or an access grant; and

code for transferring a forward link confirmation signal by the target base station to the access terminal that allows the access terminal to confirm receipt of the completion signal prior to expiration of a timer of the access terminal.

75. The computer program product of claim **74**, wherein the request signal specific to the access terminal is one of a handoff request signal employed by the access terminal to handoff from a source base station or a reserved signal utilized by the access terminal to exit a semi-connected state.

76. The computer program product of claim **74**, wherein the computer-readable medium further comprises code for determining at least one of an identity of the access terminal or a context corresponding to the access terminal based upon analyzing the request signal specific to the access terminal.

77. The computer program product of claim **74**, wherein the computer-readable medium further comprises code for transitioning to a confirmation state upon transferring the completion signal to the access terminal.

78. The computer program product of claim **74**, wherein the forward link confirmation signal is one of a forward link assignment block or an acknowledgement (ACK) to a reverse link packet.

79. The computer program product of claim **74**, wherein the computer-readable medium further comprises code for transferring the completion signal to the access terminal irrespective of buffer data being included in the request signal.

80. The computer program product of claim **74**, wherein the computer-readable medium further comprises code for recognizing at least one of handoff for the access terminal has completed or the access terminal has returned to a connected state from a semi-connected state upon detecting a reverse link confirmation signal from the access terminal.

81. The computer program product of claim **74**, wherein the computer-readable medium further comprises code for transitioning to a Non-Serving state from at least one of a Serving state or a Confirm Handoff state upon receiving a backhaul message that indicates a disparate base station serves the access terminal.

82. In a wireless communications system, a base station comprising:

a processor configured to:

receive an access terminal specific request signal from an access terminal;

transmit a completion signal to the access terminal in response to the access terminal specific request signal, the completion signal is one of a reverse link assignment block, a forward link assignment block, or an access grant; and

transmit a forward link confirmation signal to the access terminal, wherein the forward link confirmation signal enables the access terminal to confirm receipt of the completion signal prior to expiration of a timer of the access terminal.
