(57) **ABSTRACT**

Short protection control circuits and related control methods are disclosed. A disclosed short protection control circuit is adapted for controlling a short protection mechanism providing short protection to several LED chains. The disclosed short protection control circuit has a detection circuit, a first logic circuit and a timer. Coupled to the LED chains, the detection circuit asserts an indication signal when one of the node voltages of the LED chains is lower than an under-current reference. When the indication signal is enabled, the first logic circuit starts blocking the short protection mechanism. The timer times to provide a result when the short protection mechanism is blocked. When the result indicates that the short protection mechanism has been blocked for at least a predetermined time period, the first logic circuit resumes the short protection mechanism.

SHORT PROTECTION CONTROL CIRCUITS AND RELATED CONTROL METHODS

BACKGROUND OF THE INVENTION

1. Field of the Invention

The present invention relates to control methods and circuits for LED chains, and more particularly to control methods for short protection in LED chains.

2. Description of the Prior Art

In an age concerned with energy conservation and carbon reduction, light-emitting diodes (LEDs) are already a widely adopted light source due to their superior lighting efficiency and miniature component size. For example, LEDs have already replaced cold-cathode fluorescent lamps (CCFLs) as a backlight in current liquid crystal display (LCD) panels.

FIG. 1 is a diagram illustrating an LED power supply **18** used in a backlight module of an LCD panel, which is primarily used to control lighting of LED chains L_1 - L_N . Each LED chain has a plurality of series-connected LEDs. Backlight controller **20** controls a power switch of booster **19** to cause an inductive element to draw energy from input node IN, and release energy into output node OUT, so as to establish an appropriate output voltage V_{OUT} on output node OUT to drive the LED chains. Backlight controller **20** detects output voltage V_{OUT} through over-voltage protection node OVP and voltage divider resistors RD_1 , RD_2 .

Driving nodes LED_1 - LED_4 of backlight controller **20** are connected to LED chains L_1 - L_4 , respectively, for draining driving current of LED chains L_1 - L_4 , and controlling current flowing through each LED chain to be approximately equal to achieve the goal of uniform brightness.

Backlight controller **20** may also determine whether any LED encounters a fault condition from driving nodes LED_1 - LED_4 , so as to trigger related protection. For example, if LED detection voltage V_{LED-1} on driving node LED_1 is continually 0V, LED chain L_1 may be an open-circuited LED chain, where at least one LED thereof is open-circuited, in which case backlight controller **20** turns off driving of LED chain L_1 . This type of protection is typically called open circuit protection. In another example, if LED detection voltage V_{LED-1} on driving node LED_1 is much greater than LED detection voltage V_{LED-2} on driving node LED_2 , it can roughly be ascertained that LED chain L_1 has a few LEDs that are short-circuited, and driving of LED chain L_1 can be turned off. This type of protection is typically called short circuit protection.

However, open circuit protection and short circuit protection may interfere with each other. Thus, an appropriate process is needed to activate or stop open and short circuit protections, so as to achieve the desired protection effect.

SUMMARY OF THE INVENTION

According to an embodiment, a control method is used in controlling a short protection mechanism providing short protection to a plurality of light-emitting diode (LED) chains. A plurality of driving currents flow through the LED chains. The control method comprises detecting whether at least one of the driving currents encounters an under-current event; blocking a short protection mechanism when the under-current event is encountered; and resuming the short protection mechanism after the short protection mechanism is blocked for at least a predetermined time period. The short protection mechanism provides short protection to the LED chains.

According to an embodiment, a short protection control circuit is for controlling a short protection mechanism. The

short protection mechanism provides short protection applied to a plurality of light-emitting diode (LED) chains. The short protection control circuit comprises a detection circuit coupled to the LED chains for generating an indication signal whenever any terminal voltage of the LED chains is lower than an under-current reference value; a first logic circuit for starting blocking of the short protection mechanism when the indication signal is enabled; and a timer for counting time when the short protection mechanism is blocked to generate a timing result. The first logic circuit resumes the short protection mechanism after the timing result indicates that the short protection mechanism has been blocked for at least a predetermined time period.

These and other objectives of the present invention will no doubt become obvious to those of ordinary skill in the art after reading the following detailed description of the preferred embodiment that is illustrated in the various figures and drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a diagram illustrating an LED power supply used in a backlight module of an LCD panel.

FIG. 2 is a diagram of backlight controller according to an embodiment.

FIG. 3 shows one type of protection circuit.

FIG. 4 shows some signal waveforms of FIG. 2 and FIG. 3 when an LED chain becomes open-circuited.

FIG. 5 shows another protection circuit.

FIG. 6 shows FIG. 2 and FIG. 5 some signal waveforms when an LED chain becomes open-circuited.

FIG. 7 shows another detection circuit.

FIG. 8 shows an analog timer.

DETAILED DESCRIPTION

FIG. 2 is a diagram of backlight controller **20** according to an embodiment, which can be used in LED power supply **18** of FIG. 1. In some embodiments, backlight controller **20** is a monolithic integrated circuit (IC). In the present disclosure, backlight controller **20** drives four LED chains L_1 - L_4 . In other embodiments, backlight controller **20** may drive different numbers of LED chains, and is not limited to four.

In backlight controller **20**, fixed current drivers **22**₁-**22**₄ are connected to driving nodes LED_1 - LED_4 , respectively, to cause driving currents I_{LED-1} - I_{LED-4} flowing through LED chains L_1 - L_4 to be roughly equal, so that LED chains L_1 - L_4 have uniform brightness. For example, fixed current driver **22**₁ has error amplifier **24**₁, NMOS transistor N_1 , and current sense resistor RS_1 . From the circuit diagram of fixed current driver **22**₁ it can be seen that, in normal operation, driving current I_{LED-1} is approximately equal to set voltage V_{C-SET} divided by R_{RS1} , where R_{RS1} is resistance value of current sense resistor RS_1 . Fixed current drivers **22**₂-**22**₄ may be known from the description of fixed current driver **22**₁.

In some embodiments, feedback selector **26** takes the smallest of LED detection voltages V_{LED-1} - V_{LED-4} to be minimum detection voltage $V_{LED-MIN}$ for transmission to inverting terminal of error amplifier **27**. Non-inverting terminal of error amplifier **27** receives preset target voltage V_{TAR} . Pulse width adjuster **30** generates driving signal V_{DRV} according to output of error amplifier **27** to control power switch of booster **19**. Under stable conditions, minimum detection voltage $V_{LED-MIN}$ is roughly equal to target voltage V_{TAR} , which roughly causes LED power supply **18** of FIG. 1 to operate in a relatively more efficient state.

Protection circuit **28** determines whether any of LED chains L_1 - L_4 encounters a fault condition according to detection voltage V_{OVP} on over-voltage protection node OVP and LED detection voltages V_{LED-1} - V_{LED-4} on driving nodes LED₁-LED₄ to generate selection signals S_{EN-1} - S_{EN-4} . For example, fault conditions comprise LED open circuit events (at least one LED chain has an open circuit), LED short circuit events (at least one LED chain has a short circuit), etc. In other embodiments, protection circuit may determine whether any of LED chains L_1 - L_4 encounters a fault condition further (or only) according to input or output of error amplifier **24**₁-**24**₄. For example, if LED chain L_1 is identified as encountering a fault condition, protection circuit **28** disables selection signal S_{EN-1} . Disabled selection signal S_{EN-1} causes fixed current driver **22**₁ to not drive LED chain L_1 , meaning driving current I_{LED-1} becomes 0 A. Disabled selection signal S_{EN-1} also causes minimum detection voltage $V_{LED-MIN}$ to be independent of LED detection voltage V_{LED-1} , causing feedback selector **26** to not select LED detection voltage V_{LED-1} as minimum detection voltage $V_{LED-MIN}$.

LED open circuit events may cause mistaken triggering of short circuit protection. For example, LED chain L_1 may become open-circuited for some reason at a point in time, while LED chains L_2 - L_4 are normal. LED detection voltage V_{LED-1} may roughly equal 0V, causing minimum detection voltage $V_{LED-MIN}$ to also be roughly 0V, which is lower than target voltage V_{TAR} . At this time, output voltage of error amplifier **27** is pulled up continuously, and pulse width adjuster **30** causes booster **19** to increase output energy, pulling up output voltage V_{OUT} and LED detection voltages V_{LED-2} - V_{LED-4} . If careful circuit design is not employed, at this time, LED chains L_2 - L_4 are likely to be mistakenly determined as encountering LED short circuit events, which will mistakenly trigger short circuit protection, because LED detection voltages V_{LED-2} - V_{LED-4} are much greater than LED detection voltage V_{LED-1} or target voltage V_{TAR} at this time.

FIG. **3** shows one type of protection circuit **28**_a, which when used in FIG. **2**, can prevent LED open circuit events from erroneously triggering short circuit protection. Protection circuit **28**_a has detection circuit **50**, timer **57**, protection determination circuit **64**, AND gate **54**, and SR flip-flop **62**.

In detection circuit **50**, comparators **60**₁-**60**₄ respectively couple to LED chains L_1 - L_4 . Outputs of comparators **60**₁-**60**₄ couple to pulse generators **70**₁-**70**₄ having rising and falling edge triggering. Outputs of pulse generators **70**₁-**70**₄ are all connected to OR gate **52**. For the most part, any time any one LED detection voltage V_{LED-n} (where n is an integer from 1-4) is lower than under-current reference value $V_{OVER-LOW}$, comparator **60** _{n} changes state to logic "1," thereby triggering pulse generator **70** _{n} to send out a pulse as an indicator signal. This pulse passes through OR gate **52** to appear in reset signal S_{RESET} . Taking LED chain L_1 as an example, when LED detection voltage V_{LED-1} is lower than under-current reference value $V_{OVER-LOW}$, this indicates that driving current I_{LED-1} is also too low, so that LED chain L_1 is determined to have encountered an under-current event. As long as any one LED chain encounters an under-current event, a pulse will appear on reset signal S_{RESET} outputted by detection circuit **50**.

Pulse on reset signal S_{RESET} may set SR flip-flop **62**, enabling SR flip-flop **62** outputted by short circuit blocking signal $S_{SP-BLOCK}$. Pulse on reset signal S_{RESET} also resets timer **57**, causing timer **57** to return to a starting point thereof, to prepare to start counting.

Protection determination circuit **64** has LED open circuit protection circuit **66** and LED short circuit protection circuit **68**, which respectively provide open circuit protection

mechanisms and short circuit protection mechanisms. In an embodiment, when one LED chain is determined to have encountered an under-current event, and detection voltage V_{OVP} exceeds over-voltage reference value $V_{OVP-REF}$, open circuit protection mechanism provided by LED open circuit protection circuit **66** will determine that the LED chain encountered an LED open circuit event, and disable a corresponding selection signal, which is one of selection signals S_{EN-1} - S_{EN-4} . In some embodiments, when LED detection voltage V_{LED-n} exceeds a short circuit reference value V_{SP-REF} , short circuit protection mechanism of LED short circuit protection circuit **68** will determine that LED chain L_n encountered an LED open circuit event, and disable selection signal S_{EN-n} . When short circuit protection blocking signal $S_{SP-BLOCK}$ is disabled, LED short circuit protection circuit **68** operates normally to provide short circuit protection mechanisms. When short circuit protection blocking signal $S_{SP-BLOCK}$ is enabled, short circuit protection mechanisms provided by LED short circuit protection circuit **68** are blocked, meaning selection signals S_{EN-1} - S_{EN-4} are not affected by detection result of LED short circuit protection circuit **68**, or LED short circuit protection circuit **68** completely ignores LED detection voltages V_{LED-1} - V_{LED-4} .

Timer **57** has counter **56** and digital comparator **58**. Counter **56** counts according to a signal inputted by a clock. When timer results D_1 - D_{10} of counter **56** reach a certain condition, e.g. timer results D_1 - D_{10} are the same as reference values D_{S-1} - D_{S-10} , digital comparator **58** generates a pulse, resetting SR flip-flop **62**, disabling short circuit blocking signal $S_{SP-BLOCK}$, and restoring short circuit protection mechanisms provided by LED short circuit protection circuit **68**.

AND gate **54** controls clock input to counter **56**. Only when dimming signal S_{DIM} and short circuit blocking signal $S_{SP-BLOCK}$ are both enabled is clock signal CLK able to be sent to clock input of counter **56** by AND gate **54**. Dimming signal S_{DIM} being enabled represents normal LED chains (LED chains that have not been discovered to have encountered fault conditions) need to be lit. Conversely, when dimming signal S_{DIM} is disabled, all LED chains are unlit.

Simply stated, if anyone LED chain encounters an under-current event, short circuit protection blocking signal $S_{SP-BLOCK}$ will be enabled, blocking short circuit protection mechanisms, and resetting counter **56**. Counter **56** counts a paused time that passes while normal LED chains are lit, and short circuit protection blocking signal $S_{SP-BLOCK}$ is enabled. After this paused time reaches a preset time corresponding to reference value D_{S-1} - D_{S-10} , short circuit protection blocking signal $S_{SP-BLOCK}$ is disabled, restoring short circuit protection mechanisms.

In the embodiment of FIG. **3**, when short circuit protection mechanisms are blocked, if another under-current event is encountered, counter **56** will be reset again, and prepare to count again. In some embodiments, when short circuit protection mechanisms are blocked, if another under-current event occurs, counter does not necessarily restart counting.

FIG. **4** shows some signal waveforms of FIG. **2** and FIG. **3** when LED chain L_1 becomes open-circuited. From top to bottom, signals represented include detection voltage V_{OVP} , driving signal V_{DRV} , LED detection voltage V_{LED-2} , LED detection voltage V_{LED-1} , selection signal S_{EN-1} , minimum detection voltage $V_{LED-MIN}$, reset signal S_{RESET} , dimming signal S_{DIM} , timer results D_1 - D_{10} , and short circuit protection blocking signal $S_{SP-BLOCK}$.

Please refer to FIG. **2**, FIG. **3**, and FIG. **4**. In FIG. **4**, prior to time t_{OP} , LED chains L_1 - L_4 are approximately the same, and are all normal, with LED detection voltages

V_{LED-1} , V_{LED-4} and minimum detection voltage $V_{LED-MIN}$ all roughly equal to target voltage V_{TAR} .

Assume LED chain L_1 suddenly becomes open-circuited at time t_{OP} , and LED chains L_2 - L_4 are normal. Thus, at time t_{OP} , LED detection voltage V_{LED-1} and minimum detection voltage $V_{LED-MIN}$ both suddenly change to 0V. Because LED detection voltage V_{LED-1} is lower than under-current reference value $V_{OVER-LOW}$, at time t_{OP} , a pulse appears in reset signal S_{RESET} , and short circuit protection blocking signal $S_{SP-BLOCK}$ is enabled. Starting from time t_{OP} , short circuit protection mechanisms provided by LED short circuit protection circuit **68** are blocked, and short circuit protection is no longer provided.

In order to cause minimum detection voltage $V_{LED-MIN}$ to approach target voltage V_{TAR} , error amplifier **27** and pulse width adjuster **30** cause output voltage V_{OUT} and detection voltage V_{OVP} to rise together. Voltage drop across a normal LED chain is roughly fixed, so LED detection voltage V_{LED-2} rises with rising output voltage V_{OUT} . However, because LED chain L_1 is open-circuited, LED detection voltage V_{LED-1} and minimum detection voltage $V_{LED-MIN}$ stay at 0V, and do not change with varying output voltage V_{OUT} .

At time t_{OVP} , detection voltage V_{OVP} exceeds over-voltage reference value $V_{OVP-REF}$, thus LED open circuit protection circuit **66** determines that LED chain L_1 corresponding to relatively low LED detection voltage V_{LED-1} (currently 0V) encounters an LED open circuit event, and disables selection signals S_{EN-1} . Disabled selection signal S_{EN-1} causes minimum detection voltage $V_{LED-MIN}$ to break away from control of LED detection voltage V_{LED-1} , so that minimum detection voltage $V_{LED-MIN}$ suddenly jumps up, and starts to follow the minimum of other normal LED detection voltages, as shown.

After time t_{OVP} , and in order to cause minimum detection voltage $V_{LED-MIN}$ to approach target voltage V_{TAR} , output voltage V_{OUT} and detection voltage V_{OVP} slowly drop with consumed energy.

Counter **56** is reset at time t_{OP} . Then, in a dimming ON period, i.e. when dimming signal S_{DIM} is enabled, counter **56** counts with clock signal CLK. In a dimming OFF period, i.e. when dimming signal S_{DIM} is disabled, counter **56** cannot receive clock signal CLK, and pauses counting. At time t_{RCV} , timer results D_1 - D_{10} of counter **56** equal reference values D_{S-1} - D_{S-10} , and short circuit protection blocking signal $S_{SP-BLOCK}$ is disabled, restoring short circuit protection mechanisms provided by LED short circuit protection circuit **68**.

It can be seen from FIG. **4** that between time t_{OP} and time t_{RCV} , short circuit protection blocking signal $S_{SP-BLOCK}$ is enabled, so that short circuit protection of all LED chains L_1 - L_N is blocked and has no effect. It can be understood from FIG. **4** that time t_{OP} and time t_{RCV} , i.e. paused time in which short circuit protection mechanisms are blocked, is approximately equal to the sum of preset time corresponding to reference value D_{S-1} - D_{S-10} and dimming OFF period. Thus, as long as preset time is designed to be sufficiently long, even though LED detection voltage V_{LED-2} may be relatively high due to open circuiting of LED chain L_1 , LED chain L_2 will not be erroneously determined to have encountered a short circuit event.

FIG. **5** shows another protection circuit **28_b**, which when used in FIG. **2**, may prevent LED open circuit events from erroneously triggering short circuit protection. Similar or the same features of protection circuit **28_b** of FIG. **5** and protection circuit **28_a** of FIG. **3** can be understood according to the above description of FIG. **3**, and are not repeated.

Different from protection circuit **28_a** of FIG. **3**, protection circuit **28_b** of FIG. **5** additionally includes SR flip-flop **82**, comparator **80**, and AND gate **54_a**. Stated simply, after detec-

tion voltage V_{OVP} exceeds over-voltage reference value $V_{OVP-REF}$, comparator **80** sets SR flip-flop **82**, so that clock signal CLK can reach clock input of counter **56**, and counter **56** can begin counting. While comparator **58** disables short circuit protection blocking signal $S_{SP-BLOCK}$, SR flip-flop **82** is also reset, and outputs logic "0."

FIG. **6** shows FIG. **2** and FIG. **5** some signal waveforms when LED chain L_1 becomes open-circuited. From top to bottom, signals represented include detection voltage V_{OVP} , driving signal V_{DRV} , LED detection voltage V_{LED-2} , LED detection voltage V_{LED-1} , selection signal S_{EN-1} , minimum detection voltage $V_{LED-MIN}$, reset signal S_{RESET} , dimming signal S_{DIM} , timer results D_1 - D_{10} , and short circuit protection blocking signal $S_{SP-BLOCK}$.

Please refer to FIG. **5** and FIG. **6**. Even though timer results D_1 - D_{10} become 0 when counter **56** is reset at time t_{OP} , output of SR flip-flop **82** becomes logic 0, and counter **56** does not receive clock signal CLK, so that counter **56** does not start counting. Clock signal CLK must wait until after detection voltage V_{OVP} exceeds over-voltage reference value $V_{OVP-REF}$ at time t_{OVP} before being able to reach clock input of counter **56**, so that counter **56** begins to count. Thus, it can be seen from FIG. **6** that time t_{OP} and time t_{RCV} , i.e. paused time during which short circuit protection mechanisms are blocked, is roughly equal to the sum of time from time t_{OP} to time t_{OVP} , preset time corresponding to reference value D_{S-1} - D_{S-10} , and dimming OFF period. If reference values D_{S-1} - D_{S-10} are all the same, compared to paused time in FIG. **4**, paused time in FIG. **6** is longer due to additional time from time t_{OP} to time t_{OVP} .

FIG. **7** shows another detection circuit **50_a**, which replaces detection circuit **50** of FIG. **3** and FIG. **5** in some embodiments. Minimum detection voltage $V_{LED-MIN}$ roughly corresponds to minimum LED detection voltage corresponding to normal LED chains. So, minimum detection voltage $V_{LED-MIN}$ dropping below under-current reference value $V_{OVER-LOW}$ represents one lit LED chain already encountered an under-current event, so that comparator **90** causes rising-edge-triggered pulse generator **92** to emit a pulse.

FIG. **8** shows an analog timer **57_a**, which replaces digital timer **57** of FIG. **3** and FIG. **5** in some embodiments. A pulse on clock input CLK-IN can cause stepwise increase of voltage drop across capacitor **96**. When voltage drop across capacitor **96** reaches time reference voltage $V_{TIME-REF}$, comparator **94** causes rising-edge-triggered pulse generator **98** to emit a pulse. Enable signal on reset node R may cause voltage drop across capacitor **96** to become 0V, causing timer **57_a** to count again with pulses on clock input CLK-IN.

In the above embodiments, protection circuit has the following features:

Short circuit protection mechanisms are blocked after under-current events occur.

Short circuit protection mechanisms are blocked for paused time at least as long as a preset time corresponding to reference values D_{S-1} - D_{S-10} .

After each under-current event occurs, counter starts counting again.

In dimming OFF period, counter pauses counting.

Those skilled in the art will readily observe that numerous modifications and alterations of the device and method may be made while retaining the teachings of the invention. Accordingly, the above disclosure should be construed as limited only by the metes and bounds of the appended claims.

What is claimed is:

1. A control method for use in controlling a short protection mechanism providing short protection to a plurality of light-

7

emitting diode (LED) chains, wherein a plurality of driving currents flow through the LED chains, the control method comprising:

- detecting whether at least one of the driving currents encounters an under-current event; 5
- blocking a short protection mechanism and resetting a timer when the under-current event is encountered, wherein the short protection mechanism provides short protection to the LED chains; and
- resuming the short protection mechanism after the short protection mechanism is blocked for at least a predetermined time period. 10
- 2. The control method of claim 1, further comprising: resetting the timer every time the under-current event is encountered. 15
- 3. The control method of claim 1, further comprising: pausing the timer when a dimming signal is disabled.
- 4. The control method of claim 1, wherein the timer is a counter, and the counter counts according to a clock signal when the short protection mechanism is blocked. 20
- 5. The control method of claim 1, further comprising: resetting a counter every time the under-current event is encountered; and resuming the short protection mechanism when a count result of the counter exceeds a predetermined result. 25
- 6. The control method of claim 1, further comprising: detecting a smallest voltage of driving nodes of the LED chains to regulate an output power, wherein the output power is used for driving the LED chains; detecting the output power; and 30
- starting the timer after the output power exceeds an over-voltage value.
- 7. The control method of claim 1, further comprising: detecting a smallest voltage of driving nodes of the LED chains to regulate an output power, wherein the output power is used for driving the LED chains; 35
- comparing the output power with an over-voltage value; and
- starting the timer after the output power exceeds the over-voltage value and the under-current event is encountered. 40
- 8. A short protection control circuit for controlling a short protection mechanism, wherein the short protection mechanism provides short protection applied to a plurality of light-emitting diode (LED) chains, the short protection control circuit comprising: 45
- a detection circuit coupled to the LED chains for generating an indication signal whenever any terminal voltage of the LED chains is lower than an under-current reference value; 50
- a first logic circuit for starting blocking of the short protection mechanism when the indication signal is enabled; and

8

a timer for counting time when the short protection mechanism is blocked to generate a timing result; wherein the first logic circuit resumes the short protection mechanism after the timing result indicates that the short protection mechanism has been blocked for at least a predetermined time period.

9. The short protection control circuit of claim 8, wherein the detection circuit comprises:

at least one pulse generator for emitting a pulse to start blocking the short protection mechanism whenever any one of the terminal voltages is lower than the under-current reference value.

10. The short protection control circuit of claim 9, wherein the pulse resets the timer.

11. The short protection control circuit of claim 8, wherein the timer has a clock input terminal, the short protection control circuit further comprising:

a second logic circuit for sending a clock signal to the clock input terminal when a dimming signal is enabled.

12. The short protection control circuit of claim 8, wherein the timer has a clock input terminal, the short protection control circuit further comprising:

a second logic circuit coupled to the clock input terminal and the first logic circuit for blocking the clock signal from reaching the clock input terminal when the short protection mechanism is resumed.

13. The short protection control circuit of claim 8, wherein the timer has a clock input terminal, the short protection control circuit further comprising:

an over-voltage detection circuit for detecting whether an output power exceeds an over-voltage value; and a second logic circuit coupled to the clock input terminal, the first logic circuit, and the over-voltage detection circuit for blocking the clock signal from reaching the clock input terminal after the short protection mechanism is blocked and when the output power does not exceed the over-voltage value.

14. A control method for use in controlling a short protection mechanism providing short protection to a plurality of light-emitting diode (LED) chains, wherein a plurality of driving currents flow through the LED chains, the control method comprising:

- detecting whether at least one of the driving currents encounters an under-current event;
- blocking a short protection mechanism when the under-current event is encountered, wherein the short protection mechanism provides short protection to the LED chains;
- resetting a counter every time the under-current event is encountered; and
- resuming the short protection mechanism when a count result of the counter exceeds a predetermined result.
