(57) **ABSTRACT**

A boom arm extending from a chassis of an agricultural sprayer includes a plurality of chords extending outward from the sprayer and a plurality of cross-sectional frame members connecting the chords to provide structural integrity. The cross-sectional frame members include brace-receiving portions having slots formed. The boom arm has a plurality of tee-shaped brace members, each having a top flange with a stem extending therefrom. The stem is received in a slot in the brace-receiving portion of adjacent cross-section frame members. Sides of the stem and the underside of the top flange are adhesively bonded to facing surfaces of the brace-receiving portions. Each cross-sectional frame member is configured to receive an extension member that extends between the cross-sectional member and a connector mounted on the first chord. The length of the extension member is determined by the position of the cross-sectional frame member on the tapered boom arm.

MODULAR AGRICULTURAL BOOM STRUCTURE

CROSS REFERENCE TO RELATED APPLICATIONS

This application claims priority to U.S. Provisional Application No. 61/479,945 filed Apr. 28, 2011, entitled "MODULAR AGRICULTURAL BOOM STRUCTURE".

BACKGROUND OF THE INVENTION

1. Field of Invention

This invention relates generally to a sprayer boom on a crop sprayer, and more particularly to modular structure for joining members of the sprayer boom.

2. Description of Related Art

The high crop yields of modern agribusiness require application of fertilizers, pesticides, and herbicides. Dispersing these chemicals onto high acreage fields requires specialized machines mounted on or towed by a vehicle. An example of such a machine is the self-propelled crop sprayer.

A common design for a self-propelled crop sprayer includes a dedicated chassis with a tank, boom arms, and nozzles connected to the boom arms. The tank contains fluid such as fertilizers, pesticides, and herbicides. Boom arms extend outward from the sides of the dedicated chassis. Boom plumbing contains supply lines and a plurality of nozzles spaced apart along the length of the boom arms at a standard spacing distance which corresponds to the spray pattern of the nozzles. In operation, as the crop sprayer crosses the field, fluid is pumped from the tank through the supply lines along the boom arms, and out through the nozzles. This allows the self-propelled sprayer to distribute the fluid along a relatively wide path. The length of conventional boom arms may vary from, for example, 6 meters (18 feet) up to 46 meters (150 feet), but smaller or longer booms are possible. The boom arms typically swing in for transport and out for operation.

Conventionally, the boom arm has many beams, chords and braces and other structural members welded or bolted together to form a lattice structure. If the components are to be welded, the wall thickness and the choice of materials for the components can be limited. Additionally, the time to assemble and the manufacturing costs can be high.

Based on the foregoing, it would be desirable to provide a modular boom structure that enhances functionality, durability, flexibility in material choice and simplifies assembly by use of adhesives.

OVERVIEW OF THE INVENTION

In one embodiment, the invention relates to a boom arm extending from a chassis of an agricultural sprayer. The boom arm includes a plurality of chords extending outward from the agricultural sprayer and a plurality of cross-sectional frame members connecting the plurality of chords at periodic intervals to provide structural integrity. The cross-sectional frame members include brace-receiving portions having slots formed therein and the boom arm has a plurality of tee-shaped brace members, each having a top flange and a stem extending from the top flange. The stem of the tee-shaped brace member is received in slots of the brace-receiving portions of adjacent cross-section frame members, wherein sides of the stem and underside of the top flange are adhesively bonded to facing surfaces of the brace-receiving portions. In one embodiment, the boom arm has three chords arranged in a triangular formation and has a tapered shape such that the distances

2

between a first chord and second and third chords decrease along the boom arm from its proximal end closest the chassis of the agricultural sprayer to its distal end. Each cross-sectional frame member is configured to receive an extension member that extends between the cross-sectional member and a connector mounted on the first chord, wherein the length of extension member is determined by the position of the cross-sectional frame member on the tapered boom arm.

In one embodiment, each cross-sectional frame member has three legs extending from an interior junction wherein a first leg extends toward a first chord, a second leg extends toward a second chord and a third leg extends toward a third chord such that the three legs of the cross-sectional frame member form a tee shape.

In one embodiment, the slot is formed with a v-shape, with the mouth of the slot being wider than the width of the distal end of the slot, to provide some flexibility in the angular positioning of the tee-shaped bracing member. The adhesively bonded joint further includes a locking collar around an end of the tee-shaped brace. Opposite sides of the locking collar engage notches on either side of the slot to lock the stem of the tee-shaped brace member in the slot.

These and other features and advantages of this invention are described in, or are apparent from, the following detailed description of various example embodiments of the systems and methods according to this invention.

BRIEF DESCRIPTION OF THE DRAWINGS

The above mentioned and other features of this invention will become more apparent and the invention itself will be better understood by reference to the following description of embodiments of the invention taken in conjunction with the accompanying drawings, wherein:

FIG. 1 is a perspective view of a crop sprayer;

FIG. 2 is a perspective view of a portion of a boom arm on the crop sprayer of FIG. 1 according to an embodiment of the invention;

FIG. 3 is an enlarged perspective view of a portion of the boom arm of FIG. 2;

FIG. 4 is an exploded view of an embodiment of a joint of the boom arm of FIG. 2;

FIG. 5 is an enlarged perspective view of a joint of the boom arm of FIG. 2;

FIG. 6 is a perspective view of a portion of a tee-shaped bracing member of the boom arm of FIG. 2;

FIG. 7 is a partially exploded perspective view of another embodiment of a joint of the boom arm of FIG. 2; and

FIG. 8 is a perspective view of the joint of FIG. 7.

Corresponding reference characters indicate corresponding parts throughout the views of the drawings.

DESCRIPTION OF EXAMPLE EMBODIMENTS

The invention will now be described in the following detailed description with reference to the drawings, wherein preferred embodiments are described in detail to enable practice of the invention. Although the invention is described with reference to these specific preferred embodiments, it will be understood that the invention is not limited to these preferred embodiments. But to the contrary, the invention includes numerous alternatives, modifications and equivalents as will become apparent from consideration of the following detailed description.

FIG. 1 shows a crop sprayer 10 used to deliver chemicals to agricultural crops in a field. Crop sprayer 10 includes a chassis 12 and a cab 14 mounted on the chassis 12. Cab 14 may

houses an operator and a number of controls for the crop sprayer 10. An engine 16 may be mounted on a forward portion of chassis 12 in front of cab 14 or may be mounted on a rearward portion of the chassis 12 behind the cab 14. The engine 16 may be commercially available from a variety of sources and may comprise, for example, a diesel engine or a gasoline powered internal combustion engine. The engine 16 provides energy to propel crop sprayer 10 and also may provide energy used to spray fluids from the crop sprayer 10.

The crop sprayer 10 further includes a storage tank 18 used to store a fluid to be sprayed on the field. The fluid may include chemicals, such as but not limited to, herbicides, pesticides, and/or fertilizers. Storage tank 18 may be mounted on chassis 12, either in front of or behind cab 14. Crop sprayer 10 may include more than one storage tank 18 to store different chemicals to be sprayed on the field. The stored chemicals may be dispersed by crop sprayer 10 one at a time or different chemicals may be mixed and dispersed together in a variety of mixtures.

Boom arms 20 extending from each side of the crop sprayer 10 are used to distribute the fluid from the tank 18 over a wide swath as the crop sprayer 10 is driven through the field. The fluid is conveyed by a fluid supply system and various spray nozzles (not shown) spaced along the boom arms 20. As is known in the art, a pump (not shown) pumps fluid from the tank 18 through the spray nozzles. An operator of the crop sprayer 10 may use controls (not shown) located in the cab 14 to control movement of the boom arm 20 and to turn on and to shut off the fluid flow to the plurality of spray nozzles. The boom arms 20 extending from either side of the crop sprayer 10 are desirably substantially identical but mirror images of each other, so only one boom arm 20 will be discussed herein.

Turning to FIG. 2, the boom arm 20 is a truss structure having three chords 30A, 30B and 30C arranged in a triangular formation extending outward from the crop sprayer 10. At periodic intervals, cross-sectional frame members 34 connect the three chords 30A, 30B, 30C to provide structural integrity. Looking at the embodiment of the boom arm 20 from the frame of reference shown in FIG. 2, each cross-sectional frame member 34 includes a generally horizontal component 36 and a generally vertical component 38 meeting at a cross-sectional junction 40. In one example embodiment, the boom arm 20 is mounted on the crop sprayer 10 such that the horizontal and vertical components 36, 38 of the cross-sectional frame members 34 are generally horizontal and vertical with respect to the surface of the ground when the crop sprayer 10 is in use. However, one skilled in the art will understand that the boom arm 20 may be mounted on the crop sprayer 10 in other orientations such that the horizontal and vertical components 36, 38 are not respectively parallel and perpendicular with the general surface of the ground.

In the illustrated embodiment, each cross-sectional frame member 34 has three legs 42A, 42B, 42C extending from the interior junction 40. First leg 42A of cross-sectional frame member 34 extends toward chord 30A, second leg 42B extends toward chord 30B and third leg 42C extends toward chord 30C such that the three legs 42A, 42B, 42C of the cross-sectional frame member form a tee shape. In the tee-shaped embodiment illustrated in FIG. 2, the frame member 34 desirably has one or more diagonals 41 connecting two of the legs, such as the end of leg 42A with the end of leg 42C as in the illustrated embodiment. In another embodiment of the cross-sectional frame member 34, the three legs 42A, 42B and 42C are arranged in a triangular formation with the three chords 30A, 30B and 30C connecting at or near the corners of the triangular formation. Cross-sectional frame members 34 may be formed from two or more castings or welded parts or

may be of one piece constructions. Differing requirements for size of boom arm 20 may be met by selecting the size and shape of cross-sectional frame members 34 using sound engineering judgment.

In the example embodiment illustrated in FIG. 2, the boom arm 20 has a tapered shape such that the distance between chord 30A and chords 30B and 30C decreases along the boom arm 20 from its proximal end 43 closest the chassis 12 of the crop sprayer 10 out toward its distal end 44. Each cross-sectional frame member 34 is configured to receive an extension member 46 that extends between a distal end 48 of leg 42A and a connector 50A mounted on chord 30A. As can be seen in FIG. 2, the length of extension member 46 depends on the location of the cross-sectional frame member 34 on the boom arm 20. Extension members 46 are longer on the inner portions of the boom arm 20 closest to the chassis 12 of the crop sprayer 10 and decrease in length out towards the distal end 44 of the boom arm 20 as the boom arm 20 tapers. Thus, cross-sectional frame member 34 at the distal end 44 of the boom arm 20 may have a short extension member 46 or may not have an extension member 46 at all. In the illustrated embodiment, each extension member 46 is a generally rectangular beam received in a pocket 52 at the distal end 48 of leg 42A. However, one skilled in the art will understand that extension member 46 may have any other shape that is suitable to provide the requisite strength, such as U-shaped, H-shaped or I-shaped, and may connect with the end of leg 42A by any means using sound engineering judgment. In this example embodiment, the tapered boom arm 20 is made with cross-sectional frame members 34 having a uniform design and the taper of the boom arm 20 is accounted for using extension members 46 extending from leg 42A having progressively shorter lengths. Of course, one skilled in the art will understand that boom arm 20 may be constructed without a tapered shape such that cross-sectional frame members 34 and extension members 46, if any, are identical throughout the boom arm 20.

Joints of the boom arm 20 have connectors 50A, 50B, 50C that connect the cross-sectional frame member 34 to chords 30A, 30B, 30C. In one embodiment as best seen in FIG. 3, connectors 50B and 50C are integral with the legs 42B, 42C respectively of the cross-sectional frame member 34 and desirably formed by casting. Alternately, connectors 50B and 50C may be fastened to the end of legs 42B and 42C, respectively, of the cross-sectional frame members 34 with any means using sound engineering judgment. In the illustrated embodiment, connector 50A is attached at the end of the extension member 46 on leg 42A of the cross-sectional frame member 34. In one embodiment, connectors 50A, 50B, 50C have an enclosed shape that fits around chords 30A, 30B, 30C and may be fastened to the chords by welding or with suitable fasteners. However, any means to attach connectors 50A, 50B, 50C to the chords 30A, 30B, 30C may be used without departing from the scope of the invention.

As best seen in FIGS. 3 and 4, the cross-sectional frame members 34 and the connectors 50A, 50B, 50C are cast or welded with brace-receiving portions 60 configured to receive tee-shaped brace members 70. The brace receiving portion 60 may be formed as a lobe, flange or other extension of the connectors 50A, 50B, 50C and cross-sectional frame member 34. In the illustrated embodiment, the cross-sectional frame members 34 have brace-receiving portions 60 extending from each side near the junction 40 of the three legs 42A, 42B, 42C and near the connectors 50A, 50B, 50C. The brace-receiving portions 60 may be formed by casting or by plate welding. Brace-receiving portions 60 have a slot 62

5

formed therein configured to receive tee-shaped brace members 70 as will be explained below.

Tee-shaped brace member 70 is desirably extruded with a top flange 72 with a stem 74 extending therefrom to form the tee-shape. FIGS. 4 and 5 best show that the stem 74 of the tee-shaped brace member 70 fits into the slot 62 of the slotted brace-receiving portions 60. In the illustrated embodiment, the tee-shaped brace member 70 has a tee-shape along its entire length. However, one skilled in the art will understand that the tee-shape brace member 70 can have a tee-shape at its ends that join with the slotted receiving member 60 and have any other suitable shape at other points along its length.

As best seen in FIG. 6, in one embodiment the underside of the top flange 72 and sides of the stem 74 desirably have offsets 76 that form channels 78 configured to receive an adhesive (not shown). Adhesive or bonding material such as epoxy resins, hot melt adhesives, or other customary permanent adhesives that will adhere or bond similar or non-similar materials together, may be applied in the channels 78. Desirably, the size of the offsets 76 depend on what type of adhesives are used. One skilled in the art will understand that these offsets 76 are optional to get as much strength out of a certain bonding area, but are not mandatory. With the offsets the strength of a joint is more predictable. Additionally, a spacing between tee-shaped brace member 70 and the slotted brace-receiving portion 60 could also be achieved by other means without departing from the scope of the invention such as with a plastic insert that keeps tee-shaped brace member 70 and the slotted brace-receiving portion 60 apart from each other. One suitable example adhesive is Scotch-Weld™ Epoxy Adhesive DP920 available from 3M™ of St. Paul, Minn. Alternatively, offsets 76 may be formed in the inner and outer surfaces of the slotted receiving portion 60 that are adjacent the installed tee-shaped brace member 70 without departing from the scope of the invention and the adhesive or bonding material may be applied to these channels. For this adhesive, it has been determined that a height of between about 0.3 and 0.5 mm for the offsets 76 provides suitable channels 78 for the adhesive. Other heights, such as between about 0.2 and 1.0 mm may also be suitable for other adhesives. Because the joint is bonded by adhesives, the material for the tee-shaped brace member 70 and the brace-receiving portion 60 may be made from different material. The tee-shaped brace member 70 and the brace-receiving portion 60 may be made from aluminum or any other suitable material used in lattice-type structures. One skilled in the art will understand that offsets 76 may be used with all receiving pockets and structural parts in the boom arm 20 to form adhesive holding pockets such that the entire structure may be adhesively bonded. Other ways to create a distance between the surfaces such as tight positioning control, plastic insert may be used without departing from the scope of the invention. Additionally, in some instances no offsets may be necessary.

Turning now to FIGS. 7 and 8, in one embodiment the slotted receiving member 60 has a slot 62 with a v-shape. As best seen in FIG. 7, the mouth 64 of the slot 62 has a larger width than the distal end 66 of the slot 62. In some situations, such as with some brace members 70 in a tapered boom arm 20, it is desirably to have some flexibility in the angle that the brace member 70 extends from the receiving member 60. However, the adhesion between the stem 74 of the tee-shaped brace member 70 and the slotted receiving portion 60 is not optimal as forces applied by moving and twisting of the boom arm 20 may cause peel forces on the top flange 72 of the tee-shaped brace member 70. A locking collar 80 is used to lock the tee-shaped brace member 70 in the slot 60 and keep the top flange 72 of the tee-shaped brace member 70 flat

6

against the slotted receiving portion 60. In the illustrated embodiment, the slotted receiving portion 60 has notches 82 on either side of the slot 62 and sides 84 of the collar 80 are received in the notches 82 to lock the tee-shaped member 70 in the slot 62. Top portion 85 of the locking collar 80 presses against the top flange 72 of the tee-shaped brace member to keep the stem 74 in the slot 62. Locking collar 80 may be adhesively bonded, and therefore may require offsets in the notches 82 of the slotted receiving portion 60 as well to hold the adhesive. Construction of the boom arm 20 is facilitated as the joints can be successively assembled. In a three dimensional lattice structure held together by adhesives, it can be difficult to mount everything because of inserts that require room to slide into another part. Furthermore, the cut length of a part often determines the distance between two joints. With the tee-shape brace member and slotted receiving portion, it is possible to connect two structural joints by adhesive bonding in a part as if welding the two components.

An advantage of the boom arm 20 design illustrated herein is it is possible to use different materials throughout the boom arm 20. Exotic or common materials can be used, depending on demand and requirements. The wall thickness of material can be varied depending on local stresses throughout the structure, depending on plumbing and durability requirements. Thin wall stock or custom material can be used where welding would be difficult or detrimental to the properties of the material. Where high strength materials become available and welding would be more difficult, lighter boom arms 20 may be constructing as shown herein. It is believed that durability of the boom arm is improved because of the reduced number of weld spots at joints.

While this invention has been described in conjunction with the specific embodiments described above, it is evident that many alternatives, combinations, modifications and variations are apparent to those skilled in the art. Accordingly, the preferred embodiments of this invention, as set forth above are intended to be illustrative only, and not in a limiting sense. Various changes can be made without departing from the spirit and scope of this invention.

What is claimed is:

1. A boom arm mounted to a chassis of an agricultural sprayer, the boom arm comprising:
 - three chords extending outward from the agricultural sprayer, the chords arranged in a triangular formation such that the boom arm has a tapered shape with the distances between a first chord and second and third chords decreasing along the boom arm from its proximal end closest the chassis of the agricultural sprayer to its distal end;
 - a plurality of cross-sectional frame members connecting the plurality of chords at periodic intervals to provide structural integrity, wherein the cross-sectional frame members comprise brace-receiving portions having slots formed therein, wherein each cross-sectional frame member has three legs extending from an interior junction wherein a first leg extends toward a first of said chords, a second leg extends toward a second of said chords and a third leg extends toward a third of said chords such that the three legs of the cross-sectional frame member form a tee shape;
 - a plurality of tee-shaped brace members each having a top flange and a stem extending from the top flange, wherein opposite ends of each tee-shaped brace member are received by brace-receiving portions of adjacent cross-sectional frame members such that the stem of each of said tee-shaped brace members is received in the slots of its brace-receiving portions and the sides of said stem

7

and underside of said top flange of each of said tee-shaped brace members are adhesively bonded to facing surfaces of its respective brace-receiving portions; and a plurality of extension members, each of said cross-sectional frame members being configured to receive one of said extension member, wherein each extension member extends between said cross-sectional member and a connector mounted on the first chord, wherein the length of extension member is determined by the position of the cross-sectional frame member on the tapered boom arm such that the extension members decrease in length towards the distal end of the boom arm, wherein each extension member is connected at the distal end of the first leg of its cross-sectional frame member.

2. The boom arm of claim 1 wherein each extension member is a rectangular beam received in a pocket at the distal end of the first leg of its cross-sectional frame member.

3. The boom arm of claim 1, wherein the slot is v-shaped, with the mouth of the slot being wider than the width of the distal end of the slot.

4. The boom arm of claim 1, further comprising a locking collar around an end of the tee-shaped brace, wherein opposite sides of the locking collar engage notches in the brace receiving portions on either side of the slot to lock the stem of the tee-shaped brace member in the slot.

5. The boom arm of claim 1, wherein the tee-shaped brace members and the cross-sectional frame members are made of dissimilar materials.

6. The boom arm of claim 1, wherein the underside of the top flange and the sides of the stem have offsets to form adhesive-holding channels.

7. A boom arm mounted to a chassis of an agricultural sprayer, the boom arm comprising:

a plurality of chords extending outward from the agricultural sprayer;

a plurality of cross-sectional frame members connecting the plurality of chords at periodic intervals to provide structural integrity, wherein the cross-sectional frame members comprise brace-receiving portions having slots formed therein, wherein each slot is v-shaped with the mouth of the slot being wider than the width of the distal end of the slot; and

a plurality of tee-shaped brace members each having a top flange and a stem extending from the top flange, wherein

8

opposite ends of each tee-shaped brace member are received by brace-receiving portions of adjacent cross-sectional frame members such that the stem of each of said tee-shaped brace members is received in the slots of its brace-receiving portions and the sides of said stem and underside of said top flange of each of said tee-shaped brace members are adhesively bonded to facing surfaces of its respective brace-receiving portions, each tee-shaped brace member further comprising a locking collar around an end of the tee-shaped brace member, wherein opposite sides of the locking collar engage notches in the brace receiving portion on either side of the slot to lock the stem of the tee-shaped brace member in the slot.

8. The boom arm of claim 7 wherein the boom arm has three chords arranged in a triangular formation.

9. The boom arm of claim 8 wherein the boom arm has a tapered shape such that the distances between a first chord and second and third chords decrease along the boom arm from its proximal end closest the chassis of the agricultural sprayer to its distal end, wherein each cross-sectional frame member is configured to receive an extension member that extends between said cross-sectional member and a connector mounted on the first chord, wherein the length of extension member is determined by the position of the cross-sectional frame member on the tapered boom arm.

10. The boom arm of claim 9 wherein extension members decrease in length towards the distal end of the boom arm.

11. The boom arm of claim 10 wherein each cross-sectional frame member has three legs extending from an interior junction wherein a first leg extends toward a first chord, a second leg extends toward a second chord and a third leg extends toward a third chord such that the three legs of the cross-sectional frame member form a tee shape.

12. The boom arm of claim 11 wherein each cross-sectional frame member has at least one diagonal connecting ends of two of the legs.

13. The boom arm of claim 10 wherein each cross-sectional frame member has three legs arranged in a triangular formation with the three chords connecting at the corners of the triangular formation.
