(57) **ABSTRACT**

Image pickup information output apparatus which outputs information about image pickup condition derived from combination of positions/states of condition decision members serving as optical members that affect fulfillment of the condition, comprising: setting unit for setting a condition setting value as the condition to be fulfilled; controller for driving one of the condition decision members to control its position/state based on the condition setting value, condition calculator for calculating information about the condition as calculated condition based on the combination of positions/states of the condition decision members; determination unit for determining whether or not the condition setting value changed; decision unit for determining the information about condition to be output, based on the calculated condition and the determination made by the determination unit as to whether or not the condition setting value changed; and output unit for outputting information about the condition to be output determined by the decision unit.

**IMAGE PICKUP INFORMATION OUTPUT
APPARATUS AND LENS APPARATUS
EQUIPPED WITH SAME**

BACKGROUND OF THE INVENTION

1. Field of the Invention

The present invention relates to an image pickup information output apparatus adapted to output image pickup information on an image pickup system which includes a lens apparatus and an image pickup apparatus, and more particularly, to an image pickup information output apparatus adapted to output image pickup information that the lens apparatus has, in the image pickup system which includes the lens apparatus and image pickup apparatus, as well as to the lens apparatus equipped with the image pickup information output apparatus.

2. Description of the Related Art

Conventionally, an image pickup information output apparatus adapted to calculate and display object distance information, focal length information, an f-number, depth of field and an angle of view which are image pickup conditions of a camera is disclosed in Japanese Utility Model Application Laid-Open No. H01-78464, where the image pickup conditions are calculated from focus lens position, zoom lens position and stop position. Also, a three-dimensional image pickup apparatus is known which varies an optical axis angle (referred to as a convergence angle) between left and right lenses during three-dimensional photography, and thereby adjusts a three-dimensional effect of three-dimensional video. In this case, a display control apparatus which calculates and records the convergence angle or a convergence distance based on shift lens position and zoom lens position is disclosed in Japanese Patent Application Laid-Open No. 2011-135604, where the convergence distance is a distance from an image pickup apparatus to a point of intersection between the optical axes of the left and right lenses and the shift lens is used for adjustment of the optical axes.

Japanese Patent Application Laid-Open No. S63-182620 discloses a technique for automatically correcting a deviation of a focusing position by driving a focus lens according to changes in focal length, the focus lens being a varifocal lens which varies focus lens position depending on zoom lens position even when an object distance, which is an image pickup condition, is constant.

Japanese Patent Application Laid-Open No. H07-306356 discloses a technique for displaying an object distance by calculating the object distance from zoom lens position and an operating range of a focus lens, where the focus lens is a varifocal lens which varies focus lens position depending on the zoom lens position even when the object distance, which is an image pickup condition, is constant.

It becomes sometimes necessary to output image pickup conditions of an image pickup lens, such as the object distance, f-number, focal length, depth of field, angle of view, convergence distance at a given time point to the outside such as to an image pickup operator. Since it is necessary to output information about an actual state in which image pickup is performed, when information about the image pickup conditions are acquired from a state of a lens apparatus itself, the image pickup conditions need to be computed and found from positions of plural optical members including the focus lens, zoom lens, stop, and shift lens. Furthermore, these optical members vary with plural image pickup conditions. This involves trouble because even if the image pickup conditions set by the operator is not changed, if a setting of another image pickup condition is changed, image pickup condition information

2

will change. To deal with this, a lens control apparatus is disclosed which makes automatic corrections such that even if an image pickup condition changes, other image pickup conditions will not be affected. However, there can arise a problem in that image pickup condition information will change due to calculation errors in image pickup condition information even if image pickup conditions are fixed during an automatic correction process if changes occur in position detection accuracy errors as a result of synchronization delays among plural optical members or changes in travel ranges of the optical members.

For example, the above problem will be described concretely by taking as an example the object distance of a varifocal lens. With a varifocal lens, position of the focus lens with respect to a predetermined object distance is a function of zoom lens position, and thus the object distance can be found from the focus lens position and zoom lens position. Therefore, in setting an object distance, a targeted focus lens position is determined from the set object distance and zoom lens position. Furthermore, since the zoom lens position changes during the setting of focal length, in order to keep the object distance constant, the focus lens position needs to be adjusted automatically according to the zoom lens position. Automatic object distance adjustment such as described above is disclosed in Japanese Patent Application Laid-Open No. S63-182620.

Furthermore, an object distance display apparatus for a varifocal lens is disclosed in Japanese Patent Application Laid-Open No. H07-306356, where the display apparatus calculates and displays an object distance based on zoom lens position and focus lens position.

Consequently, even if the focal length changes, the object distance can be displayed by maintaining a set object distance.

However, since the focus lens is driven and the object distance is calculated according to zoom lens position, if there is a delay in driving the focus lens with respect to variations in zoom lens position, the focus lens cannot be moved in an instant to the focus lens position corresponding to targeted object distance in response to a change in the focal length, and consequently, the object distance calculated from the zoom lens position and focus lens position deviates by the amount corresponding to the delay in following the change in the focal length. Furthermore, the travel range of the focus lens from infinity to the closest range varies between when the zoom lens position is on a wide-angle side and when the zoom lens position is on a telephoto side while position detection accuracy remains constant even when the focus lens moves, and consequently, the accuracy of object distance corresponding to the focus lens position varies with the focal length. Therefore, since the accuracy of object distance varies with the focal length even if the object distance is the same, the object distance changes even if the automatic object distance adjustment described above is carried out according to the focal length. The change in the object distance may cause the photographer to misunderstand that the lens is malfunctioning. The same is similarly true for the f-number, focal length, depth of field, angle of view, convergence distance in addition to the object distance.

The conventional techniques disclosed in the patent documents described above do not describe how to deal with changes in object distance caused by synchronization errors of the lens or lens position detection accuracy.

SUMMARY OF THE INVENTION

Thus, the present invention provides an image pickup information output apparatus for a camera, wherein when

3

image pickup condition settings are not changed, even if another image pickup condition setting is made, the image pickup information output apparatus does not change image pickup condition information as long as the change of another image pickup condition information is within an allowable range.

To achieve the above object, the present invention provides an image pickup information output apparatus which outputs information about an image pickup condition of a lens apparatus by driving a movable optical member so as to satisfy the image pickup condition, the image pickup information being derived from positions of a plurality of image pickup condition decision optical members which are optical members that affect satisfaction of the image pickup condition, the image pickup information output apparatus including: a setting unit adapted to set an image pickup condition setting value as a position of the movable optical member which satisfies the image pickup condition; a drive controller for driving a movable optical member which is one of the image pickup condition decision optical members to control a position or state of the movable optical member based on the image pickup condition setting value; an image pickup condition calculator adapted to calculate the information about the image pickup condition as a calculated image pickup condition based on the positions of the plurality of image pickup condition decision optical members; a determination unit adapted to determine whether or not there is any change in the image pickup condition setting value; a decision unit adapted to determine image pickup condition information to be output, based on the calculated image pickup condition and the determination made by the determination unit as to whether or not there is any change in the image pickup condition setting value; and an output unit adapted to output information about the image pickup condition.

The present invention can provide an image pickup information output apparatus for a camera, wherein when image pickup condition settings are not changed, even if another image pickup condition setting is made, the image pickup information output apparatus does not change image pickup condition information. This prevents the photographer from misunderstanding that the lens is malfunctioning.

Further features of the present invention will become apparent from the following description of exemplary embodiments with reference to the attached drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a configuration block diagram according to a first embodiment.

FIG. 2 is a diagram illustrating a relationship among object distance (in-focus object distance), focus lens position, and zoom lens position.

FIG. 3 is a diagram illustrating a relationship between sub-target object distance and object distance with the elapsed time.

FIG. 4 is a diagram illustrating a relationship between sub-target focal length and zoom lens target position.

FIG. 5 is a diagram illustrating a relationship between sub-target object distance and focal length with the elapsed time.

FIG. 6 is a flowchart diagram illustrating procedures for detecting any change in an object distance setting value (image pickup condition setting value).

FIG. 7 is a flowchart diagram illustrating procedures for determining output object distance information.

FIG. 8 is a configuration block diagram according to a second embodiment.

4

FIG. 9 is a diagram for illustrating convergence distance.

FIG. 10 is a diagram illustrating a relationship among convergence distance position, shift lens position, and zoom lens position.

FIG. 11 is a diagram illustrating a relationship between sub-target convergence distance and convergence distance with the elapsed time.

FIG. 12 is a flowchart diagram illustrating procedures for detecting any change in a convergence distance setting value (image pickup condition setting value).

FIG. 13 is a flowchart illustrating procedures for determining output convergence distance information.

DESCRIPTION OF THE EMBODIMENTS

Preferred embodiments of the present invention will now be described in detail in accordance with the accompanying drawings.

First Embodiment

A first embodiment of the present invention will be described below with reference to FIG. 1.

FIG. 1 is a configuration block diagram according to the first embodiment. A system illustrated by way of example in the first embodiment includes a lens apparatus 10 adapted to control a movable optical member related to picking up image, an object distance operating unit 11 which is a setting unit connected to the lens apparatus 10, a focal length operating unit 12, an image pickup apparatus 13, and an external display apparatus 14 connected to the image pickup apparatus 13.

The object distance operating unit 11 is used to operate an object distance (in-focus object distance) of the lens apparatus 10 and is made up, for example, of a demand (focus demand) and a camera. The focal length operating unit 12 is used to operate focal length of the lens apparatus 10 and is made up, for example, of a demand (zoom demand) and a camera. The image pickup apparatus 13, which is, for example, a camera, is adapted to capture an object image formed by the lens apparatus 10. The external display apparatus 14 is adapted to display image pickup condition information such as an object distance and is made up, for example, of a viewfinder.

The lens apparatus 10 includes a focus lens 105 used for focus adjustment and a zoom lens 115 used for zoom adjustment.

The focus lens 105 is driven under the control of a focus lens drive controller (drive controller) 104 made up of, for example, a control computation unit and a motor. Position of the focus lens 105 is detected by a focus lens position detector 106 made up of, for example, a Hall element. An object distance (image pickup condition) set command value from the object distance operating unit 11 is input to an object distance set command input unit 101. An object distance set command value (image pickup condition setting value) is input to a sub-target object distance calculator 102, which then calculates a sub-target object distance which provides a target position for the object distance in each control cycle. A method of calculating the sub-target object distance will be described later. Based on the sub-target object distance and current zoom lens position, a focus lens target position calculator 103, which is a sub-target value calculator, calculates a target position (movable optical member target position) of the focus lens per unit time. A method of calculating the movable optical member target position (the focus lens target position) will be described later. The focus lens drive control-

5

ler 104 performs drive control such that the focus lens position will match a focus lens target position value.

The zoom lens 115 is driven under the control of a zoom lens drive controller 114 made up of, for example, a control computation unit and a motor. A position of the zoom lens 115 is detected by a zoom lens position detector 116 made up of, for example, a Hall element. A focal length set command from the focal length operating unit 12 is input to a focal length setting command input unit 111. A focal length set command value is input to a sub-target focal length calculator 112, which then calculates a sub-target focal length which provides a target position for the focal length in each control cycle. A method of calculating the sub-target focal length will be described later. Based on the sub-target focal length, a zoom lens target position calculator 113 calculates a target position of the zoom lens per unit time. A method of calculating the zoom lens target position will be described later. The zoom lens drive controller 114 performs drive control such that the zoom lens position will match the zoom lens target position.

An object distance calculator 121 which is an image pickup condition calculator calculates object distance information (image pickup condition information) as a calculated image pickup condition based on the focus lens position from the focus lens position detector 106 and the zoom lens position from the zoom lens position detector 116. A method of calculating the object distance will be described later. A set-object-distance-change determination unit 122, which is a determination unit, determines whether or not set object distance changed. A method of determining whether or not set object distance changed will be described later. An object distance decision unit 123, which is a decision unit, determines output object distance information, which is object distance information to be output to the outside. A method of determining the output object distance information will be described later. An object distance output unit 124, which is an output unit, outputs the output object distance information, which is output image pickup condition information, to the outside. According to the present embodiment, the output object distance information is output from the object distance output unit 124 to the image pickup apparatus 13.

Next, a method of calculating the focus lens target position will be described.

The focus lens target position F_c can be calculated from sub-target object distance D_{tc} and zoom lens position Z_p . FIG. 2 illustrates a relationship among the object distance (in-focus object distance) D_p , focus lens target position F_c , and zoom lens position Z_p . The object distance D_p and sub-target object distance D_{tc} have the same units, and can be considered to be equivalent to each other. To calculate the focus lens target position F_c , it is common practice to convert characteristics as illustrated in FIG. 2 into tabular data in advance and derive the focus lens target position F_c using the object distance D_p and zoom lens position Z_p as parameters. For example, if the zoom lens position Z_p is Z_{p1} and the sub-target object distance D_{tc} is $D1$, the focus lens target position F_c is $F1$. Also, if the zoom lens position Z_p is Z_{p1} and the sub-target object distance D_{tc} is $D2$, the focus lens target position F_c is $F2$.

Note that the set command value of the object distance (in-focus object distance) described above may not necessarily be the object distance (in-focus object distance) itself but can be a normalized value of the object distance (in-focus object distance).

Next, a method of calculating the sub-target object distance will be described.

6

FIG. 3 illustrates a relationship between the sub-target object distance D_{tc} and object distance D_p with the elapsed time when the object distance setting value (image pickup condition setting value) D_c changes from D_{c1} to D_{c2} , where T_0 represents the time at which the object distance setting value D_c changes from D_{c1} to D_{c2} and a unit time ΔT corresponds to the duration of a control cycle. A maximum variation amount D_{tcMax} of the sub-target object distance corresponds to a maximum stroke of the object distance D_p can cover within the unit time ΔT . The maximum variation amount D_{tcMax} of the sub-target object distance can be calculated based on a maximum stroke F_{cMax} of the focus lens per unit time ΔT and tabular data which represents characteristics as illustrated in FIG. 2. For example, when the zoom lens position Z_p is Z_{p1} , if focus lens position F_p moves by the maximum stroke F_{cMax} from $F1$ to $F2$ within the unit time ΔT , travel distance of the focus lens position is $|F2-F1|$, and $|D2-D1|$ corresponding thereto is the maximum variation amount D_{tcMax} of the sub-target object distance. A value changed by the maximum variation amount D_{tcMax} of the sub-target object distance is calculated every unit time ΔT until the sub-target object distance D_{tc} reaches the object distance setting value D_{c2} . This control allows the actual zoom lens position to keep up with a value indicated every unit time, and consequently, stable control can be achieved without increases in the difference between the target position and the actual position.

Next, a method of calculating the zoom lens target position will be described.

Zoom lens target position Z_c can be calculated from sub-target focal length A_{tc} . FIG. 4 illustrates a relationship between the sub-target focal length A_{tc} and zoom lens target position Z_c . As illustrated in FIG. 4, the relationship between the focal length and zoom lens position is represented by a linear function. To calculate the zoom lens target position Z_c , it is common practice to actually measure the relationship between the focal length and zoom lens position as illustrated in FIG. 4, convert the measurements into tabular data in advance, and derive the zoom lens target position Z_c . For example, when the sub-target focal length A_{tc} is $A1$, the zoom lens target position Z_c is Z_{c2} .

Next, a method of calculating the sub-target focal length will be described.

FIG. 5 illustrates a relationship between the sub-target focal length A_{tc} and focal length A_p with the elapsed time when a focal length setting value A_c changes from A_{c1} to A_{c2} , where T_0 represents the time at which the focal length setting value A_c changes from A_{c1} to A_{c2} and a unit time ΔT corresponds to the duration of a control cycle. A maximum variation amount A_{tcMax} of the sub-target focal length corresponds to a maximum stroke of the focal length A_p within the unit time ΔT . The maximum variation amount A_{tcMax} of the sub-target focal length can be calculated based on a maximum stroke Z_{cMax} of the zoom lens per unit time ΔT and tabular data which represents characteristics as illustrated in FIG. 4. Since the sub-target focal length A_{tc} and zoom lens target position Z_c are proportional to each other as illustrated in FIG. 4, the zoom lens target position Z_c is represented by a relationship expressed in Eq. (1).

$$Z_c = (A_{tc} \times C11) + C12 \quad (1)$$

where $C11$ and $C12$ are predetermined constants determined from measured data.

The maximum stroke Z_{cMax} per unit time ΔT can be calculated from Eq. (2).

$$Z_{cMax} = (A_{tcMax} \times C1) + C2 \quad (2)$$

A value of the sub-target focal length changed by the maximum variation amount Δt_{cMax} is calculated every unit time ΔT until the sub-target focal length A_{tc} reaches the focal length setting value A_{c2} .

Next, a method of calculating the object distance (image pickup condition information) will be described.

The object distance D_p can be calculated from the focus lens position F_p and zoom lens position Z_p . That is, the object distance D_p (image pickup condition information) can be calculated by use of the focus lens position F_p and the zoom lens position Z_p as a combination of the plurality of image pickup condition decision optical members. To calculate the object distance D_p , it is common practice to convert characteristics as illustrated in FIG. 2 into tabular data in advance and derive the object distance D_p using the table. For example, when the zoom lens position Z_p is Z_{p1} and the focus lens position F_p is $F1$, the object distance D_p is $D1$. Also, when the zoom lens position Z_p is Z_{p1} and the focus lens position F_p is $F2$, the object distance D_p is $D2$.

As can be seen from FIG. 2, variation amounts of the focus lens position F_p relative to changes in the object distance are smaller when the zoom lens position Z_p is on the wide-angle side than when the zoom lens position Z_p is on the telephoto side. Position detection accuracy of the focus lens position F_p is equal over the entire operating range of the focus lens, and consequently, the position detection accuracy with respect to changes in the object distance D_p is lower when the zoom lens position Z_p is on the wide-angle side than when the zoom lens position Z_p is on the telephoto side. Consequently, even if the object distance setting value (image pickup condition setting value) is the same, the object distance D_p has larger position errors when the zoom lens position Z_p is on the wide-angle side than when the zoom lens position Z_p is on the telephoto side. Therefore, even if the set value of the object distance is not changed, the object distance D_p computed on the wide-angle side of the zoom lens position Z_p may have a different value. Thus, if the object distance D_p is displayed as it is, when zoom position is changed, even if the object distance setting value is not changed, the object distance D_p can change as well, causing the photographer to misunderstand that the lens is malfunctioning.

Next, a method of determining any change in the object distance setting value will be described.

FIG. 6 is a flowchart illustrating procedures for detecting any change in a setting of the object distance.

Processing is started in S101, and then the flow goes to S102.

In S102, a current sub-target object distance D_{tc2} is calculated, and then the flow goes to S103.

In S103, it is determined whether or not a difference between the sub-target object distance D_{tc1} stored in the previous time period and the current sub-target object distance D_{tc2} is equal to or greater than a predetermined threshold value greater than 0. If the difference is equal to or greater than the threshold value, the flow goes to S104. If the difference is smaller than the threshold value, the flow goes to S106.

In S104, the current sub-target object distance D_{tc2} is held for use in a next determination as a sub-target object distance D_{tc1} stored in the previous time period. Then, the flow goes to S105.

In S105, it is determined that the object distance setting value changed. Then, the flow goes to S107.

In S106, it is determined that the object distance setting value remains unchanged. Then, the flow goes to S107.

In S107, the processing is finished.

In this way, it is determined whether or not the object distance settings changed.

Although in the process of S103, the sub-target object distance D_{tc} is used as an instance to be determined whether or not the object distance setting value (hereinafter, also referred to as a set-condition-change determination value) changed, the object distance setting value D_c may be used as a set-condition-change determination value.

Furthermore, the focus lens target position F_c and zoom lens position Z_p may be used as set-condition-change determination values. In that case, when the focus lens target position F_c is changed with the zoom lens position Z_p remaining unchanged, it can be determined that the focus lens is driven by changes in the object distance setting value rather than by a focal length setting. Therefore, it may be determined that the object distance setting value changed when an amount of change in the focus lens target position F_c is equal to or greater than a predetermined threshold value and an amount of change in the zoom lens position Z_p is equal to or smaller than a predetermined threshold value.

Furthermore, the sub-target focal length A_{tc} , focal length setting value A_c , zoom lens target position Z_c , zoom lens position Z_p or focal length A_p may be used as a set-condition-change determination value.

In that case, when a focal length setting is being made, even if the object distance setting value D_c does not change, the object distance D_p will change. Therefore, if it is determined that a focal length setting is being made, processing similar to that used when there is no change in the object distance setting value is performed to prevent unnecessary fluctuations of the object distance information output from the object distance output unit 124 to equipment outside the lens apparatus 10.

Furthermore, although in the present embodiment, the zoom lens is not moved according to the object distance setting value D_c , if the zoom lens is to be moved according to the object distance setting value D_c , changes in the object distance setting value may be determined based on a relationship between the focus lens target position F_c and zoom lens target position Z_c . In that case, when an amount of change in the object distance target position derived from the focus lens target position F_c and zoom lens target position Z_c as well as the characteristics in FIG. 2 is within a predetermined threshold value, it may be determined that the object distance setting value remains unchanged.

Next, a method of determining the output object distance information will be described. FIG. 7 is a flowchart illustrating procedures for determining output object distance information D_{po} .

Processing is started in S201, and then the flow goes to S202.

In S202, the current object distance is calculated as the latest object distance D_{p2} , and then the flow goes to S203.

In S203, it is determined whether or not the object distance setting value changed. If it is determined that it changed, the flow goes to S206. If it is determined that there is no change, the flow goes to S204.

In S204, by establishing the time point at which determination as to whether or not the object distance setting value switched from "changed" to "remains unchanged" in the previous process as the start time of a no-change period, it is determined whether or not an elapsed time from the start time of the no-change period is equal to or longer than a fixed time period T_{lim1} (a first time period which is a predetermined time period longer than 0). A state in which the elapsed time is shorter than the first time period is defined to be an update state and a state in which the elapsed time is equal to or longer

than the first time period is defined to be a preservation state. By taking control delays between the sub-target object distance D_{tc} and object distance D_p into consideration, the fixed time period T_{lim1} is set to the unit time ΔT .

If it is determined in S204 that the fixed time period T_{lim1} has elapsed, the flow goes to S205. If it is determined that the fixed time period T_{lim1} has not elapsed, the flow goes to S206.

In S205, if the difference between the output object distance information D_{po} and the latest object distance D_{p2} is equal to or greater than a predetermined threshold value ΔD_{lim} (equal to or greater than a first threshold value) greater than 0, the flow goes to S206. If the difference between the output object distance information D_{po} and the latest object distance D_{p2} is smaller than the predetermined threshold value ΔD_{lim} (smaller than the first threshold value), the flow goes to S208. The threshold value ΔD_{lim} is set to a value larger than an amount of change in the object distance D_p brought about when the focal length is changed from a wide-angle end to a telephoto end, by measuring the amount of change in advance.

In S206, the latest object distance D_{p2} is held as a previous object distance D_{p1} , and then the flow goes to S207. In S207, the latest object distance D_{p2} (first image pickup condition information) is determined to be output object distance information D_{po} (output image pickup condition information), and then the flow goes to S209. In S208, the previous object distance D_{p1} (second image pickup condition information) is determined to be output object distance information D_{po} , and then the flow goes to S209. In S209, the processing is finished.

In the process of S208, instead of the previous object distance D_{p1} , the sub-target object distance D_{tc} may be determined as output object distance information. Also, a driving period calculated from the difference between the object distance setting value D_c and object distance D_p may be set as the fixed time period T_{lim1} . Furthermore, instead of the previous object distance D_{p1} , the object distance setting value D_c may be determined as the output object distance information D_{po} .

Next, processes of the first embodiment will be described.

The object distance setting value D_c output from the object distance operating unit 11 is received by the object distance set command input unit 101 and output to the sub-target object distance calculator 102. The sub-target object distance calculator 102 calculates the sub-target object distance D_{tc} from the object distance setting value D_c and outputs the sub-target object distance D_{tc} to the focus lens target position calculator 103. The focus lens target position calculator 103 calculates the focus lens target position F_c from the sub-target object distance D_{tc} and zoom lens position Z_p and outputs the focus lens target position F_c to the focus lens drive controller 104. Based on the focus lens target position F_c , the focus lens drive controller 104 drives the focus lens 105 by performing control such that the focus lens position F_p will match the focus lens target position F_c . The focus lens position detector 106 detects the focus lens position F_p and outputs the focus lens position F_p to the object distance calculator 121.

The focal length setting value A_c output from the focal length operating unit 12 is received by the focal length setting command input unit 111 and output to the sub-target focal length calculator 112. The sub-target focal length calculator 112 calculates the sub-target focal length A_{tc} from the focal length setting value A_c and outputs the sub-target focal length A_{tc} to the zoom lens target position calculator 113. The zoom lens target position calculator 113 calculates the zoom lens target position Z_c from the sub-target focal length A_{tc} and outputs the zoom lens drive target position Z_c to the zoom

lens drive controller 114. Based on the zoom lens target position Z_c , the zoom lens drive controller 114 drives the zoom lens 115 by performing control such that the zoom lens position Z_p will match the zoom lens target position Z_c . The zoom lens position detector 116 detects the zoom lens position Z_p and outputs the zoom lens position Z_p to the object distance calculator 121.

The object distance calculator 121 calculates the object distance (in-focus object distance)

D_p from the focus lens position F_p and zoom lens position Z_p and outputs the object distance D_p to the object distance decision unit 123. The set-object-distance-change determination unit determines, based on the sub-target object distance D_{tc} , whether or not the object distance setting value changed and outputs a result of the determination to the object distance decision unit 123. Based on the object distance D_p as well as on the determination result as to whether or not the object distance setting value changed, the object distance decision unit 123 determines output object distance information (information on image pickup conditions to be output) and outputs the output object distance to the object distance output unit 124. The object distance output unit 124 outputs the output object distance information to the image pickup apparatus 13. The image pickup apparatus 13 outputs the output object distance information to the external display apparatus 14.

This enables implementing an image pickup information output apparatus which can avoid a situation in which regardless of the object distance setting value being not changed, the object distance information (in-focus object distance information) to be output is changed due to changes in the focus lens position and zoom lens position or changes in focus lens position detection accuracy.

Although in the first embodiment described above, the object distance setting value from the object distance operating unit is a position command which specifies a target position, similar effects can be obtained even when a velocity command is used. This can be implemented by a method in which the object distance set command input unit 101 calculates the object distance setting value D_c from reference position and a velocity command value. For example, when the velocity command value starts to be received, using the object distance D_p as a reference position, the object distance setting value D_c can be calculated by adding an amount of position change corresponding to the velocity command value to the reference position at each lapse of a unit time.

Also, although in the example described in the first embodiment, the display apparatus is installed outside the lens apparatus 10, the output object distance information may be displayed by installing the display apparatus in the lens apparatus 10.

Furthermore, in the example described above, the image pickup condition is the object distance (in-focus object distance), the movable optical member is the focus lens, and the image pickup condition decision optical members are the focus lens and zoom lens, but similar effects can be obtained when the image pickup condition to be output is depth of field and the movable optical member is a stop and the optical members (image pickup condition decision optical members) which affect the determination (the fulfillment) of the image pickup condition are the focus lens, zoom lens and stop. Note that in such case, the focus lens position, the zoom lens position and the state of stop (f-number) are used to derive the image pickup condition information (depth of field). That is, the focus lens position, the zoom lens position and the state of stop (f-number) are used as the combination of the image pickup condition decision optical members.

A method of calculating the depth of field Df will be described below.

The depth of field Df can be calculated from a rear depth of field Dpb and front depth of field Dpf using Eq. (3), where the rear depth of field Dpb is that part of the depth of field which is located behind the object distance Dp (on the infinity side) while the front depth of field is that part of the depth of field which is located in front of the object distance Dp (on the closest side), the depth of field being a range in which the object in focus appears sharp.

$$Df = Dpb + Dpf \quad (3)$$

Furthermore, the rear depth of field Dpb and front depth of field Dpf can be calculated from the object distance Dp, the focal length Ap, a permissible circle of confusion σ , and an f-number Fno, using equations (4) and (5), respectively.

$$Dpf = (\sigma \times Fno \times Dp^2) / (Ap^2 + (\sigma \times Fno \times Dp)) \quad (4)$$

$$Dpb = (\sigma \times Fno \times Dp^2) / (Ap^2 - (\sigma \times Fno \times Dp)) \quad (5)$$

Thus, the depth of field Df can be calculated using equations (3), (4) and (5).

If the depth of field Df is calculated by the above method and the object distance is replaced with the depth of field, an image pickup information output apparatus can be implemented in which the depth of field is neither changed by changes in the focus lens position and zoom lens position unless the depth of field is changed intentionally nor the depth of field is affected by changes in focus lens position detection accuracy.

Second Embodiment

Next, a second embodiment of the present invention will be described with reference to FIG. 8.

FIG. 8 is a configuration block diagram according to the present embodiment, wherein the same components as those in FIG. 1 are denoted by the same reference numerals as the corresponding components in FIG. 1.

In the second embodiment, a method of displaying a convergence distance in a three-dimensional image pickup apparatus will be described.

A lens apparatus 20 and lens apparatus 21 are adapted to control movable optical members for the left eye and right eye, respectively, during photography. The lens apparatus 21 is identical in configuration to the lens apparatus 20. A convergence distance operating unit 22 serving as a setting unit is used to operate the convergence distance between the lens apparatus 20 and lens apparatus 21 and connected to the lens apparatus 20 and lens apparatus 21. The convergence distance operating unit 22 is made up of, for example, a demand and camera. The focal length operating unit 23 is used to operate the focal length of the lens apparatus 20 and lens apparatus 21 and connected to the lens apparatus 20 and lens apparatus 21. The focal length operating unit 23 is made up of, for example, a demand and camera.

The lens apparatus 20 according to the present embodiment includes a shift lens 205 and a shift lens position detector 206, where the shift lens 205 moves in a direction having components perpendicular to optical axes of the respective lens apparatus to move an object image formed on an imaging surface, and thereby producing an effect equivalent to moving optical axis directions of the lens apparatus while the shift lens position detector 206 is made up of, for example, a Hall element.

Besides, the lens apparatus 20 according to the present embodiment includes a convergence distance setting com-

mand input unit 201, a sub-target convergence distance calculator 202, a shift lens target position calculator 203, a shift lens drive controller 204, a convergence distance calculator 221 serving as an image pickup condition calculator, a set-convergence-distance-change determination unit 222, a convergence-distance decision unit 223 and a convergence distance output unit 224.

The convergence distance setting command input unit 201 receives a convergence distance setting value (image pickup condition setting value) from outside and the sub-target convergence distance calculator 202 calculates a sub-target convergence distance which provides a target position for the convergence distance in each control cycle based on convergence distance setting value received by the convergence distance setting command input unit 201. A method of calculating the sub-target convergence distance will be described later. Based on the sub-target convergence distance and current zoom lens position, the shift lens target position calculator 203, which is a sub-target value calculator, calculates a target position of the shift lens per unit time. A method of calculating the shift lens target position will be described later. The shift lens drive controller 204, which is made up of, for example, a control computation unit and a motor, performs drive control such that the shift lens position will match the shift lens target position.

The convergence distance calculator 221 calculates the convergence distance based on the shift lens position and zoom lens position. A method of calculating the convergence distance will be described later. The set-convergence-distance-change determination unit 222 serving as a determination unit determines whether or not the convergence distance setting value changed. A method of determining whether or not the convergence distance setting value changed will be described later. The convergence distance decision unit 223 serving as a decision unit determines convergence distance information to be output to the outside. A method of determining output convergence distance information will be described later. The convergence distance output unit 224 serving as an output unit outputs the convergence distance information, which is output image pickup condition information, to the outside.

Next, convergence distance will be described.

FIG. 9 is a diagram illustrating a relationship among a field lens L, a field lens R, the convergence distance Cp, base length a, an optical axis VL, an optical axis VR, a convergence point p and a convergence angle θ . The optical axis VL is the optical axis of the lens apparatus 20 while the optical axis VR is the optical axis of the lens apparatus 21. The base length a is an interval between the optical axes in the image pickup apparatus, and specifically, is a distance between a center of the field lens L and a center of the field lens R. The convergence point p is a point at which the optical axes VL and VR intersect each other. The convergence angle θ is an angle formed by the optical axes VL and VR intersecting each other at the convergence point p. The convergence distance Cp is the distance from a line joining the field lens L and field lens R of the left and right image pickup apparatuses to the convergence point p.

As illustrated in FIG. 9, the lens apparatus 20 and lens apparatus 21 perform control to drive the shift lenses 205 in opposite directions such that the optical axes VL and VR will move in the opposite directions and intersect each other at the convergence point p.

A relationship among the convergence distance Cp, base length a and convergence angle θ is given by Eq. (6).

$$Cp = (a/2) / \tan(\theta/2) \quad (6)$$

If video shot with the convergence distance C_p is projected onto a screen, a viewer can view three-dimensional video by visually perceiving the video from the lens apparatus **20** with the left eye and the video from the lens apparatus **21** with the right eye. In this case, if the convergence distance C_p which is the distance to the convergence point given as a point of intersection between the optical axes VL and VR is shorter than the distance from the viewer to the screen, the viewer feels as if the object were located in front of the screen and if the convergence distance C_p is longer than the distance from the viewer to the screen, the viewer feels as if the object were located behind the screen.

Next, a method of calculating the shift lens target position will be described.

The shift lens target position S_c can be calculated from the sub-target convergence distance C_{tc} and zoom lens position Z_p . FIG. **10** illustrates a relationship among the convergence distance position C_p , shift lens target position S_c , and zoom lens position Z_p . The convergence distance position C_p and sub-target convergence distance C_{tc} have the same units, and can be considered to be equivalent to each other. To calculate the shift lens target position S_c , it is common practice to convert characteristics as illustrated in FIG. **10** into tabular data in advance and derive the shift lens target position S_c . For example, if the zoom lens position Z_p has a value of Z_{p1} and the sub-target convergence distance C_{tc} has a value of $C1$, the shift lens target position S_c has a value of $S1$. Also, if the zoom lens position Z_p has a value of Z_{p1} and the sub-target convergence distance C_{tc} has a value of $C2$, the shift lens target position S_c has a value of $S2$.

With reference to a position at which the optical axis VL and optical axis VR are parallel to each other, the lens apparatus **21** is controlled so as to move the optical axis VL by the same amount at the same angle as the optical axis VR in a direction opposite to the optical axis VR of the lens apparatus **20**.

As can be seen from FIG. **10**, amounts of change in the shift lens position S_p relative to changes in the convergence distance are smaller when the zoom lens position Z_p is on the wide-angle side than when the zoom lens position Z_p is on the telephoto side. Position detection accuracy of the shift lens position S_p is equal over the entire operating range of the shift lens, and consequently, the position detection accuracy with respect to changes in the convergence distance C_p is lower when the zoom lens position Z_p is on the wide-angle side than when the zoom lens position Z_p is on the telephoto side. Consequently, even if the convergence distance setting value is the same, the convergence distance C_p has larger amounts of position error when the zoom lens position Z_p is on the wide-angle side than when the zoom lens position Z_p is on the telephoto side. Therefore, the convergence distance C_p computed on the wide-angle side of the zoom lens position Z_p may have a different value. Thus, displaying the convergence distance C_p with no change may cause the photographer to misunderstand that the lens is malfunctioning because changing zoom position causes the convergence distance C_p changed regardless of the convergence distance setting value being not changed.

Next, a method of calculating the sub-target convergence distance will be described.

FIG. **11** illustrates a relationship between the sub-target convergence distance C_{tc} and convergence distance C_p with the elapsed time when a convergence distance setting value (image pickup condition setting value) C_c changes from C_{c1} to C_{c2} , where T_0 represents the time at which the convergence distance setting value C_c changes from C_{c1} to C_{c2} and a unit time ΔT corresponds to the duration of a control cycle.

A maximum variation amount C_{tcMax} of the sub-target convergence distance corresponds to a maximum stroke of the convergence distance C_p within the unit time ΔT . The maximum variation amount C_{tcMax} of the sub-target convergence distance can be calculated based on a maximum stroke S_{cMax} of the shift lens per unit time ΔT and tabular data which represents characteristics as illustrated in FIG. **10**. For example, when the zoom lens position Z_p is Z_{p1} and the shift lens position S_p is $S1$, if the maximum stroke S_{cMax} is $|S2-S1|$, then the maximum variation amount C_{tcMax} of the sub-target convergence distance is $|C2-C1|$. A value changed by the maximum variation amount C_{tcMax} of the sub-target convergence distance is calculated every unit time ΔT until the sub-target convergence distance C_{tc} reaches the convergence distance setting value C_{c2} .

Next, a method of detecting changes in the convergence distance setting value will be described.

FIG. **12** is a flowchart illustrating procedures for detecting any change in the convergence distance setting value.

Processing is started in **S301**, and then the flow goes to **S302**.

In **S302**, current sub-target convergence distance C_{tc2} is calculated, and then the flow goes to **S303**.

In **S303**, it is determined whether or not a difference between the sub-target convergence distance C_{tc1} stored in the previous time period and the current sub-target convergence distance C_{tc2} is equal to or greater than a predetermined threshold value greater than 0. If the difference is equal to or greater than the threshold value, the flow goes to **S304**. If the difference is smaller than the threshold value, the flow goes to **S306**.

In **S304**, the current sub-target convergence distance C_{tc2} is held for use in a next determination as a sub-target convergence distance C_{tc1} stored in the previous time period. Then, the flow goes to **S305**.

In **S305**, it is determined that the convergence distance setting value changed. Then, the flow goes to **S307**.

In **S306**, it is determined that the convergence distance setting value remains unchanged. Then, the flow goes to **S307**.

In **S307**, the processing is finished.

In this way, any change in the convergence distance setting value is detected.

Although in the process of **S302**, the sub-target convergence distance C_{tc} is used as an instance to be determined whether or not the convergence distance setting value changed, the convergence distance setting value C_c may be used as an instance to be checked for the change.

Furthermore, the shift lens target position S_c and zoom lens position Z_p may be used as the instances to be checked for the change. In that case, when the shift lens target position S_c is changed with the zoom lens position Z_p remaining unchanged, it can be determined that the shift lens is driven by changes in the convergence distance setting value rather than by a focal length setting. Therefore, it may be determined that there is a change in the convergence distance setting value when an amount of change in the shift lens target position S_c is equal to or greater than a predetermined threshold value (equal to or greater than a second threshold value) greater than 0 and an amount of change in the zoom lens position Z_p is equal to or smaller than a predetermined threshold value (equal to or smaller than a third threshold value) greater than 0.

Furthermore, the sub-target focal length A_{tc} , focal length setting value A_c , zoom lens target position Z_c , zoom lens position Z_p or focal length A_p may be used as the instance to be checked for the change.

In that case, when a focal length setting is being made, even if the convergence distance setting value C_c does not change, the convergence distance C_p will change. Therefore, if it is determined that a focal length setting is being made, processing similar to that used when the convergence distance setting value remains unchanged is performed to prevent unnecessary fluctuations of the convergence distance C_p , which is the convergence distance information output from the convergence distance output unit **224** to equipment outside the lens apparatus **20**.

Furthermore, although in the present embodiment, the zoom lens position is not moved according to the convergence distance setting value C_c , if the zoom lens position is to be moved according to the convergence distance setting value C_c , changes in the convergence distance setting value may be determined based on a relationship between the shift lens target position S_c and zoom lens target position Z_c . In that case, when an amount of change in the convergence distance target position derived from the shift lens target position S_c and zoom lens target position Z_c as well as the characteristics in FIG. 2 is within a predetermined threshold value greater than 0, it may be determined that there is no change in the convergence distance setting value.

Next, a method of determining the output convergence distance information will be described.

FIG. 13 is a flowchart illustrating procedures for determining output convergence distance information C_{po} .

Processing is started in **S401**, and then the flow goes to **S402**.

In **S402**, current convergence distance is calculated as the latest convergence distance C_{p2} , and then the flow goes to **S403**.

In **S403**, it is determined whether or not the convergence distance setting value changed. If it is determined that the convergence distance setting value changed, the flow goes to **S406**. If it is determined that the convergence distance setting value remains unchanged, the flow goes to **S404**.

In **S404**, by establishing the time point at which determination as to whether or not the convergence distance setting value changed switched from “changed” to “remains unchanged” in the previous process as the start time of a no-change period, it is determined whether or not an elapsed time from the start time of the no-change period is equal to or longer than a fixed time period T_{lim2} .

By taking control delays between the sub-target convergence distance C_{tc} and convergence distance C_p into consideration, the fixed time period T_{lim2} is set to the unit time ΔT .

If it is determined in **S404** that the fixed time period T_{lim2} has elapsed, the flow goes to **S405**. If it is determined that the fixed time period T_{lim2} has not elapsed, the flow goes to **S406**.

In **S405**, if the difference between the output convergence distance information C_{po} and the latest convergence distance C_{p2} is equal to or greater than a predetermined threshold value ΔC_{lim} (equal to or greater than a first threshold value) greater than 0, the flow goes to **S406**. If the difference between the output convergence distance information C_{po} and the latest convergence distance C_{p2} is smaller than the predetermined threshold value ΔC_{lim} (smaller than the first threshold value), the flow goes to **S408**. The threshold value ΔC_{lim} is set to a value larger than an amount of change in the convergence distance C_p brought about when the focal length is changed from the wide-angle end to the telephoto end, by measuring the amount of change in advance.

In **S406**, the latest convergence distance C_{p2} is held as a previous convergence distance C_{p1} , and then the flow goes to **S407**. In **S407**, the latest convergence distance C_{p2} (first

image pickup condition information) is determined to be output convergence distance information C_{po} (output image pickup condition information), and then the flow goes to **S409**. In **S408**, the previous convergence distance C_{p1} (second image pickup condition information) is determined to be output convergence distance information C_{po} , and then the flow goes to **S409**. In **S409**, the processing is finished.

In the process of **S408**, instead of the previous convergence distance C_{p1} , convergence distance target position C_{pc} may be determined as output convergence distance information. Also, a driving period calculated from the difference between the convergence distance setting value C_c and convergence distance C_p may be set as the fixed time period T_{lim2} . Furthermore, instead of the previous convergence distance C_{p1} , the convergence distance setting value C_c may be determined as the output convergence distance information C_{po} .

Next, processes of the second embodiment will be described.

The convergence distance setting value C_c output from the convergence distance operating unit **22** is received by the convergence distance setting command input unit **201** and output to the sub-target convergence distance calculator **202**. The sub-target convergence distance calculator **202** calculates the sub-target convergence distance C_{tc} from the convergence distance setting value C_c and outputs the sub-target convergence distance C_{tc} to the shift lens target position calculator **203**. The shift lens target position calculator **203** calculates the shift lens target position S_c from the sub-target convergence distance C_{tc} and zoom lens position Z_p and outputs the shift lens target position S_c to the shift lens drive controller **204**. Based on the shift lens target position S_c , the shift lens drive controller **204** controls to drive the shift lens **205** so that the shift lens position S_p matches the shift lens target position S_c . The shift lens position detector **206** detects the shift lens position S_p and outputs the shift lens position S_p to the convergence distance calculator **221**.

The focal length setting value A_c output from the focal length operating unit **23** is received by the focal length setting command input unit **111** and output to the sub-target focal length calculator **112**. The sub-target focal length calculator **112** calculates the sub-target focal length A_{tc} from the focal length setting value A_c and outputs the sub-target focal length A_{tc} to the zoom lens target position calculator **113**. The zoom lens target position calculator **113** calculates the zoom lens target position Z_c from the sub-target focal length A_{tc} and outputs the zoom lens target position Z_c to the zoom lens drive controller **114**. Based on the zoom lens target position Z_c , the zoom lens drive controller **114** controls to drive the zoom lens **115** so that the zoom lens position Z_p match the zoom lens target position Z_c . The zoom lens position detector **116** detects the zoom lens position Z_p and outputs the zoom lens position Z_p to the convergence distance calculator **221**.

The convergence distance calculator **221** calculates the convergence distance C_p based on the shift lens position S_p and zoom lens position Z_p and outputs the convergence distance C_p to the convergence distance decision unit **223**. That is, the convergence distance C_p (image pickup condition information) can be calculated by use of the shift lens position S_p and the zoom lens position Z_p as a combination of the plurality of image pickup condition decision optical members. The set-convergence-distance-change determination unit determines, based on the sub-target convergence distance C_{tc} , whether or not the convergence distance setting value changed and outputs a result of the determination to the convergence distance decision unit **223**. Based on the convergence distance C_p as well as on the determination result as to whether or not convergence distance setting value changed,

17

the convergence distance decision unit 223 determines output convergence distance information and outputs the output convergence distance information to the convergence distance output unit 224. The convergence distance output unit 224 outputs the output convergence distance information to the image pickup apparatus 13. The image pickup apparatus 13 outputs the output convergence distance information to the external display apparatus 14.

This enables implementing an image pickup information output apparatus which can avoid a situation in which the convergence distance information to be output is changed due to changes in the shift lens position and zoom lens position or changes in shift lens position detection accuracy regardless of the convergence distance setting value remaining unchanged.

Although in the present embodiment, a shift lens for optical axis adjustment is used to control the convergence distance, a variable apex angle prism may be used instead of the shift lens. Alternatively, similar effects can be obtained if the angle formed by the optical axes of the two lens apparatuses is directly controlled by mechanically panning each of the two lens apparatuses.

In the configurations illustrated by way of example in the above embodiments, operating units such as the object distance operating unit 11, focal length operating units 12 and 23, and convergence distance operating unit 22 are provided on cameras and demands, the external display apparatus 14 is connected to the image pickup apparatus 13, and the other components are included in the lens apparatuses 10 and 20. However, the present invention is not limited to this. Except optical components such as the lenses and stop as well as drive controllers and position detectors therefor, the components included in the lens apparatus 10 or 20 illustrated in FIG. 1 or 8 may be provided on apparatuses except the lens apparatus, for example, in a console device, camera, or independent control apparatus. Conversely, although operating units such as the object distance operating unit 11, focal length operating units 12 and 23, and convergence distance operating unit 22 as well as the external display apparatus have been described as being installed outside the lens apparatus, this is not restrictive, and effects of the present invention can be achieved similarly even if these components are installed in the lens apparatus. Although the convergence distance is exemplified as the image pickup condition in the second embodiment described above, the convergence angle can be used as the image pickup condition to obtain the advantageous effect of the present invention.

While the present invention has been described with reference to exemplary embodiments, it is to be understood that the invention is not limited to the disclosed exemplary embodiments and that various modifications and changes can be made within the scope of the invention. The scope of the following claims is to be accorded the broadest interpretation so as to encompass all such modifications and equivalent structures and functions.

This application claims the benefit of Japanese Patent Application No. 2011-219535, filed Oct. 3, 2011, which is hereby incorporated by reference herein in its entirety.

What is claimed is:

1. An image pickup information output apparatus which outputs information about an image pickup condition derived from a combination of positions or states of a plurality of image pickup condition decision optical members serving as optical members that affect fulfillment of the image pickup condition, comprising:

a setting unit configured to set an image pickup condition setting value as the image pickup condition to be fulfilled;

18

a drive controller configured to drive a movable optical member which is one of the image pickup condition decision optical members to control a position or state of the movable optical member based on the image pickup condition setting value;

an image pickup condition deriving unit configured to derive an information about the image pickup condition as a derived image pickup condition based on the combination of positions or states of the plurality of image pickup condition decision optical members;

a determination unit configured to determine whether or not the image pickup condition setting value changed;

a decision unit configured to determine the information about image pickup condition to be output, based on the information about the derived image pickup condition and the determination made by the determination unit as to whether or not the image pickup condition setting value changed; and

an output unit configured to output information about the image pickup condition to be output determined by the decision unit,

wherein the decision unit determines a first image pickup condition as the information about image pickup condition to be output when the determination unit determines the image pickup condition setting value being changed, and determines a second image pickup condition, which is different from the first image pickup condition, as the information about image pickup condition to be output when the determination unit does not determine the image pickup condition setting value being changed.

2. An image pickup information output apparatus which outputs information about an image pickup condition derived from a combination of positions or states of a plurality of image pickup condition decision optical members serving as optical members that affect fulfillment of the image pickup condition, comprising:

a setting unit configured to set an image pickup condition setting value as the image pickup condition to be fulfilled;

a drive controller configured to drive a movable optical member which is one of the image pickup condition decision optical members to control a position or state of the movable optical member based on the image pickup condition setting value;

an image pickup condition deriving unit configured to derive an information about the image pickup condition as a derived image pickup condition based on the combination of positions or states of the plurality of image pickup condition decision optical members;

a determination unit configured to determine whether or not the image pickup condition setting value changed;

a decision unit configured to determine the information about image pickup condition to be output, based on the information about the derived image pickup condition and the determination made by the determination unit as to whether or not the image pickup condition setting value changed; and

an output unit configured to output information about the image pickup condition to be output determined by the decision unit,

wherein:

the determination unit determines whether or not the image pickup condition setting value changed based on a set-condition-change determination value representing a change in the image pickup condition setting value;

the decision unit determines a state from a time when the determination unit determines that the image pickup

19

condition setting value changed until a first time period elapses as an update state and determines a state other than the update state as a preservation state; and the decision unit sets a first image pickup condition information as the image pickup condition information to be output in the update state while sets a second image pickup condition information as the image pickup condition information to be output in the preservation state.

3. An image pickup information output apparatus which outputs information about an image pickup condition derived from a combination of positions or states of a plurality of image pickup condition decision optical members serving as optical members that affect fulfillment of the image pickup condition, comprising:

a setting unit configured to set an image pickup condition setting value as the image pickup condition to be fulfilled;

a drive controller configured to drive a movable optical member which is one of the image pickup condition decision optical members to control a position or state of the movable optical member based on the image pickup condition setting value;

an image pickup condition deriving unit configured to derive an information about the image pickup condition as a derived image pickup condition based on the combination of positions or states of the plurality of image pickup condition decision optical members;

a determination unit configured to determine whether or not the image pickup condition setting value changed;

a decision unit configured to determine the information about image pickup condition to be output, based on the information about the derived image pickup condition and the determination made by the determination unit as to whether or not the image pickup condition setting value changed; and

an output unit configured to output information about the image pickup condition to be output determined by the decision unit,

wherein:

the determination unit determines whether or not the image pickup condition setting value changed based on a set-condition-change determination value representing a change in the image pickup condition setting value;

the decision unit determines a state from a time when the determination unit determines that the image pickup condition setting value changed until a first time period elapses to be an update state and determines a state other than the update state to be a preservation state; and

the decision unit sets a first image pickup condition information as the image pickup condition information to be output in the update state, while in the preservation state, the decision unit sets the first image pickup condition information as the image pickup condition information to be output when a difference between the first image pickup condition information and a second image pickup condition information is equal to or greater than a first threshold value and sets the second image pickup condition information as the image pickup condition information to be output when the difference is smaller than the first threshold value.

4. The image pickup information output apparatus according to claim 3, wherein the first threshold value is greater than an amount of change of the first image pickup condition information when the image pickup condition setting value is not changed.

20

5. The image pickup information output apparatus according to claim 2, wherein:

the set-condition-change determination value comprises the image pickup condition setting value; and

the determination unit determines that the image pickup condition setting value changed in a case where an amount of change in the set-condition-change determination value is equal to or greater than a predetermined threshold value.

6. The image pickup information output apparatus according to claim 2, wherein:

the set-condition-change determination value comprises a set value of another image pickup condition which affects operation of the movable optical member; and

the determination unit determines that the image pickup condition setting value remains unchanged in a case where an amount of change in the set-condition-change determination value is equal to or greater than a predetermined threshold value.

7. The image pickup information output apparatus according to claim 2, wherein:

the set-condition-change determination value comprises a position of an image pickup condition decision optical member other than the movable optical member; and

the determination unit determines that the image pickup condition setting value remains unchanged in a case where an amount of change in the set-condition-change determination value is equal to or greater than a predetermined threshold value.

8. The image pickup information output apparatus according to claim 2, further comprising a unit configured to derive a movable optical member target position from the image pickup condition setting value, the movable optical member target position being a drive target position of the movable optical member,

wherein the set-condition-change determination value comprises the drive target position and a position of an image pickup condition decision optical member other than the movable optical member; and

the determination unit determines that the image pickup condition setting value changed in a case where an amount of change in the movable optical member target position is equal to or greater than a second threshold value and an amount of change in the set-condition-change determination value is equal to or smaller than a third threshold value.

9. The image pickup information output apparatus according to claim 2, further comprising a unit configured to derive movable optical member target positions based on the image pickup condition setting value, the movable optical member target positions being respective target positions of two or more movable optical members,

wherein the set-condition-change determination value comprises drive target positions of the respective image pickup condition decision optical members; and

the determination unit determines whether or not the image pickup condition setting value changed based on a relationship among the drive target positions of the respective image pickup condition decision optical members.

10. The image pickup information output apparatus according to claim 2, further comprising:

a sub-target value deriving unit configured to derive a sub-target value based on the image pickup condition setting value and on the image pickup condition information derived by the image pickup condition deriving unit, the sub-target value serving as a target for the image pickup condition within a unit time; and

21

a unit configured to control driving of the movable optical member according to the sub-target value, wherein the set-condition-change determination value comprises the sub-target value.

11. The image pickup information output apparatus according to claim 2, wherein:

the first image pickup condition information is the latest image pickup condition information derived by the image pickup condition deriving unit; and

the second image pickup condition information is image pickup condition information derived by the image pickup condition deriving unit immediately before a change from the update state to the preservation state.

12. The image pickup information output apparatus according to claim 2, wherein:

the first image pickup condition information is the latest image pickup condition information derived by the image pickup condition deriving unit; and

the second image pickup condition information is the image pickup condition setting value.

13. The image pickup information output apparatus according to claim 10, wherein:

the first image pickup condition information is the latest image pickup condition information derived by the image pickup condition deriving unit; and

the second image pickup condition information is the sub-target value.

14. The image pickup information output apparatus according to claim 1, wherein:

the image pickup condition is an object distance;

the movable optical member is a focus lens; and

the plurality of image pickup condition decision optical members comprises the focus lens and a zoom lens.

15. An image pickup information output apparatus which outputs information about an image pickup condition derived from a combination of positions or states of a plurality of image pickup condition decision optical members serving as optical members that affect fulfillment of the image pickup condition, comprising:

a setting unit configured to set an image pickup condition setting value as the image pickup condition to be fulfilled;

a drive controller configured to drive a movable optical member which is one of the image pickup condition decision optical members to control a position or state of the movable optical member based on the image pickup condition setting value;

an image pickup condition deriving unit configured to derive an information about the image pickup condition as a derived image pickup condition based on the combination of positions or states of the plurality of image pickup condition decision optical members;

a determination unit configured to determine whether or not the image pickup condition setting value changed;

a decision unit configured to determine the information about image pickup condition to be output, based on the information about the derived image pickup condition and the determination made by the determination unit as to whether or not the image pickup condition setting value changed; and

an output unit configured to output information about the image pickup condition to be output determined by the decision unit,

wherein:

the image pickup condition is a convergence distance or a convergence angle;

22

the movable optical member is a shift lens for optical axis adjustment or a variable apex angle prism; and the plurality of image pickup condition decision optical members comprises a shift lens or a variable apex angle prism, and a zoom lens.

16. The image pickup information output apparatus according to claim 1, wherein:

the image pickup condition is a depth of field;

the movable optical member is a stop; and

the plurality of image pickup condition decision optical members comprises the stop, a focus lens and a zoom lens.

17. A lens apparatus comprising:

an image pickup information output apparatus which outputs information about an image pickup condition derived from a combination of positions or states of a plurality of image pickup condition decision optical members serving as optical members that affect fulfillment of the image pickup condition, the image pickup information output apparatus comprising:

a setting unit configured to set an image pickup condition setting value as the image pickup condition to be fulfilled;

a drive controller configured to drive a movable optical member which is one of the image pickup condition decision optical members to control a position or state of the movable optical member based on the image pickup condition setting value;

an image pickup condition deriving unit configured to derive an information about the image pickup condition as a derived image pickup condition based on the combination of positions or states of the plurality of image pickup condition decision optical members;

a determination unit configured to determine whether or not the image pickup condition setting value changed;

a decision unit configured to determine the information about image pickup condition to be output, based on the information about the derived image pickup condition and the determination made by the determination unit as to whether or not the image pickup condition setting value changed; and

an output unit configured to output information about the image pickup condition determined by the decision unit, wherein the decision unit determines a first image pickup condition as the information about image pickup condition to be output when the determination unit determines the image pickup condition setting value being changed, and determines a second image pickup condition, which is different from the first image pickup condition, as the information about image pickup condition to be output when the determination unit does not determine the image pickup condition setting value being changed.

18. An information output apparatus, comprising:

a setting unit configured to set an object distance setting value;

a drive controller configured to control a drive of a focus lens so as to suppress a change of an object distance information which is based on a change of a position of a zoom lens;

a deriving unit configured to derive the object distance information based on a position of the focus lens and a position of the zoom lens;

a determination unit configured to determine whether or not the object distance setting value changed; and

an output unit configured to output a first object distance information derived by the deriving unit or a second object distance information derived prior to the first

23

object distance information by the deriving unit based on the determination made by the determination unit, wherein the output unit outputs the first object distance information when the determination unit determines the object distance setting value being changed, and continues to output the second object distance information when the determination unit does not determine the object distance setting value being changed.

19. The information output apparatus according to claim 18, configured such that:

the determination unit determines whether or not the object distance setting value changed based on a set-condition-change determination value representing a change in the object distance setting value; the output unit determines a state from a time when the determination unit determines that the object distance setting value changed until a first time period elapses as an update state and determines a state other than the update state as a preservation state; and

the output unit sets the first object distance information as the object distance information to be output in the update state while sets the second object distance information as the object distance information to be output in the preservation state.

20. The information output apparatus according to claim 18, configured such that:

the determination unit determines whether or not the object distance setting value changed based on a set-condition-change determination value representing a change in the object distance setting value;

the output unit determines a state from a time when the determination unit determines that the object distance setting value changed until a first time period elapses to be an update state and determines a state other than the update state to be a preservation state; and

the output unit sets the first object distance information as the object distance information to be output in the update state, while in the preservation state, the output unit sets the first object distance information as the object distance information to be output when a difference between the first object distance information and the second object distance information is equal to or greater than a first threshold value and sets the second object distance information as the object distance information to be output when the difference is smaller than the first threshold value.

21. The information output apparatus according to claim 20, wherein the first threshold value is greater than an amount of change of the first object distance information when the object distance setting value is not changed.

22. The information output apparatus according to claim 19, wherein:

the set-condition-change determination value comprises the object distance setting value; and

the determination unit is configured to determine that the object distance setting value changed in a case where an amount of change in the set-condition-change determination value is equal to or greater than a predetermined threshold value.

23. The information output apparatus according to claim 19, wherein:

the set-condition-change determination value comprises a set value which affects operation of the focus lens; and the determination unit is configured to determine that the object distance setting value remains unchanged in a case where an amount of change in the set-condition-

24

change determination value is equal to or greater than a predetermined threshold value.

24. The information output apparatus according to claim 19, wherein:

the set-condition-change determination value comprises a position of the zoom lens; and

the determination unit is configured to determine that the object distance setting value remains unchanged in a case where an amount of change in the set-condition-change determination value is equal to or greater than a predetermined threshold value.

25. The information output apparatus according to claim 19, further comprising a unit configured to calculate a focus lens target position from the object distance setting value, the focus lens target position being a drive target position of the focus lens,

wherein the set-condition-change determination value comprises the drive target position and a position of the zoom lens; and

the determination unit is configured to determine that the object distance setting value changed in a case where an amount of change in the focus lens target position is equal to or greater than a second threshold value and an amount of change in the set-condition-change determination value is equal to or smaller than a third threshold value.

26. The information output apparatus according to claim 19, further comprising a unit configured to calculate focus lens target positions based on the object distance setting value, the focus lens target positions being respective target positions of two or more focus lenses,

wherein the set-condition-change determination value comprises drive target positions of the focus lens and the zoom lens; and

the determination unit is configured to determine whether or not the object distance setting value changed based on a relationship among the drive target positions of the focus lens and the zoom lens.

27. The information output apparatus according to claim 19, further comprising:

a sub-target value calculator configured to calculate a sub-target value based on the object distance setting value and on the object distance information derived by the deriving unit, the sub-target value serving as a target for the object distance information within a unit time; and a unit configured to control driving of the focus lens according to the sub-target value,

wherein the set-condition-change determination value comprises the sub-target value.

28. The information output apparatus according to claim 19, wherein:

the first object distance information is the latest object distance information derived by the deriving unit; and the second object distance information is object distance information derived by the deriving unit immediately before a change from the update state to the preservation state.

29. The information output apparatus according to claim 19, wherein:

the first object distance information is the latest object distance information derived by the deriving unit; and the second object distance information is the object distance setting value.

30. The information output apparatus according to claim 27, wherein:

the first object distance information is the latest object distance information derived by the deriving unit; and

25

the second object distance information is the sub-target value.

31. A lens apparatus comprising:

a focus lens;

a zoom lens;

an information output apparatus, comprising:

a setting unit configured to set an object distance setting value;

a drive controller configured to control a drive of the focus lens so as to suppress a change of an object distance information which is based on a change of a position of the zoom lens;

a deriving unit configured to derive the object distance information based on a position of the focus lens and a position of the zoom lens;

a determination unit configured to determine whether or not the object distance setting value changed; and

an output unit configured to output a first object distance information derived by the deriving unit or a second object distance information derived prior to the first object distance information by the deriving unit based on the determination made by the determination unit,

wherein the output unit outputs the first object distance information when the determination unit determines the object distance setting value being changed, and continues to output the second object distance information when the determination unit does not determine the object distance setting value being changed.

32. An information output apparatus, comprising:

a setting unit configured to set a depth of field setting value;

a drive controller configured to control a drive of a stop so as to suppress a change of a depth of field information which is based on a change of at least one of a position of a focus lens and a position of a zoom lens;

a deriving unit configured to derive the depth of field information based on a state of the stop, a position of the focus lens and a position of the zoom lens;

a determination unit configured to determine whether or not the depth of field setting value changed; and

an output unit configured to output a first depth of field information derived by the deriving unit or a second depth of field information derived prior to the first depth of field information by the deriving unit based on the determination made by the determination unit,

wherein the output unit outputs the first depth of field information when the determination unit determines the depth of field setting value being changed, and outputs the second depth of field information when the determination unit does not determine the depth of field setting value being changed.

33. A lens apparatus comprising:

a stop;

a focus lens;

a zoom lens;

an information output apparatus, comprising:

a setting unit configured to set a depth of field setting value;

a drive controller configured to control a drive of the stop so as to suppress a change of a depth of field information which is based on a change of at least one of a position of the focus lens and a position of the zoom lens;

a deriving unit configured to derive the depth of field information based on a state of the stop, a position of the focus lens and a position of the zoom lens;

a determination unit configured to determine whether or not the depth of field setting value changed; and

an output unit configured to output a first depth of field information derived by the deriving unit or a second

26

depth of field information derived prior to the first depth of field information by the deriving unit based on the determination made by the determination unit, wherein the output unit outputs the first depth of field information when the determination unit determines the depth of field setting value being changed, and outputs the second depth of field information when the determination unit does not determine the depth of field setting value being changed.

34. An information output apparatus, comprising:

a setting unit configured to set a convergence distance setting value;

a drive controller configured to control a drive of a shift lens or a variable apex angle prism so as to suppress a change of a convergence distance information which is based on a change of a position of a zoom lens;

a deriving unit configured to derive the convergence distance information based on a position of the shift lens or a state of the variable apex angle prism, and a position of the zoom lens;

a determination unit configured to determine whether or not the convergence distance setting value changed; and

an output unit configured to output a first convergence distance information derived by the deriving unit or a second convergence distance information derived prior to the first convergence distance information by the deriving unit based on the determination made by the determination unit, wherein the output unit outputs the first convergence distance information when the determination unit determines the convergence distance setting value being changed, and outputs the second convergence distance information when the determination unit does not determine the convergence distance setting value being changed.

35. A lens apparatus comprising:

a shift lens or a variable apex angle prism;

a zoom lens;

an information output apparatus, comprising:

a setting unit configured to set a convergence distance setting value;

a drive controller configured to control a drive of the shift lens or the variable apex angle prism so as to suppress a change of a convergence distance information which is based on a change of a position of the zoom lens;

a deriving unit configured to derive the convergence distance information based on a position of the shift lens or a state of the variable apex angle prism, and a position of the zoom lens;

a determination unit configured to determine whether or not the convergence distance setting value changed; and

an output unit configured to output a first convergence distance information derived by the deriving unit or a second convergence distance information derived prior to the first convergence distance information by the deriving unit based on the determination made by the determination unit, wherein the output unit outputs the first convergence distance information when the determination unit determines the convergence distance setting value being changed, and outputs the second convergence distance information when the determination unit does not determine the convergence distance setting value being changed.

36. An information output apparatus, comprising:

a setting unit configured to set a convergence angle setting value;

27

a drive controller configured to control a drive of a shift lens or a variable apex angle prism so as to suppress a change of a convergence angle information which is based on a change of a position of a zoom lens;

a deriving unit configured to derive the convergence angle information based on a position of the shift lens or a state of the variable apex angle prism, and a position of the zoom lens;

a determination unit configured to determine whether or not the convergence angle setting value changed; and

an output unit configured to output a first convergence angle information derived by the deriving unit or a second convergence angle information derived prior to the first convergence angle information by the deriving unit based on the determination made by the determination unit,

wherein the output unit outputs the first convergence angle information when the determination unit determines the convergence angle setting value being changed, and outputs the second convergence angle information when the determination unit does not determine the convergence angle setting value being changed.

37. A lens apparatus comprising:

a shift lens or a variable apex angle prism;

a zoom lens;

an information output apparatus, comprising:

28

a setting unit configured to set a convergence angle setting value;

a drive controller configured to control a drive of the shift lens or the variable apex angle prism so as to suppress a change of a convergence angle information which is based on a change of a position of the zoom lens;

a deriving unit configured to derive the convergence angle information based on a position of the shift lens or a state of the variable apex angle prism, and a position of the zoom lens;

a determination unit configured to determine whether or not the convergence angle setting value changed; and

an output unit configured to output a first convergence angle information derived by the deriving unit or a second convergence angle information derived prior to the first convergence angle information by the deriving unit based on the determination made by the determination unit,

wherein the output unit outputs the first convergence angle information when the determination unit determines the convergence angle setting value being changed, and outputs the second convergence angle information when the determination unit does not determine the convergence angle setting value being changed.
