This invention was made with government support under Grant Number CCF-0926148 awarded by the National Science Foundation. The government has certain rights in the invention.

BACKGROUND OF THE INVENTION

1. Field of the Invention

The present invention relates to capacitive actuators and more specifically to systems and methods for driving capacitive actuators.

2. Brief Description of the Related Art

Many actuation technologies, including piezoelectric actuators, electrostatic actuators, and dielectric elastomer actuators, have a capacitive nature. From an electrical perspective, these technologies present two important challenges. Firstly, since capacitive actuators rely on high electric fields or high electro-static pressure to operate, they generally require high drive voltages (tens to thousands of volts). Secondly, the capacitive structure of the actuators can store a large amount of electrical energy that is not converted into mechanical output; to increase system efficiency, it is highly desirable to recover this energy.

These challenges complicate power electronics design in actuation systems, particularly in mobile applications with power or weight constraints. Mobile devices are typically powered by a battery with limited capacity, which requires high efficiency to extend battery life. At the same time, the output voltage of the battery is typically much lower than the required drive voltage of capacitive actuators.

Switching-mode drive circuits are highly efficient electronic circuits which can be used, in appropriate configurations, to supply power to capacitive actuators, amplify the battery voltage to the level required by the actuators, and recover unused energy from the actuators. Such circuits typically consist of semiconductor switches, capacitors, and magnetic components (inductors and transformers). Due to the compact nature of semiconductor devices and surface-mount capacitors, inductors and transformers are frequently the heaviest and most expensive components of the drive circuits. To this end, it is desirable to minimize the number of magnetic components in a drive circuit, particularly in mobile applications. This is problematic in a system with several capacitive actuators. Typically, at least one magnetic component is required to step up the power supply (i.e. battery) voltage to a level required to drive the actuators, and one additional magnetic component per actuator is necessary to enable energy recovery.

An example of a prior art system is shown in U.S. Pat. No. 6,549,432 entitled "Single-Winding, Multiple Output, Bi-Directional Flyback Converter," which discloses a multiple-output bidirectional flyback converter. Such a converter would allow energy delivery from a low-voltage supply to several high-voltage loads, and from the loads back to the supply. The disclosed circuit, however, does not provide for transfer of energy directly from one load to another. To achieve such a transfer in that disclosed system, one would have to first transfer energy from a load to the supply, then from the supply to a different load. Two energy transfers instead of one results in additional losses and ties up the magnetic element for a longer time, which reduces the bandwidth of the drive circuit.

Another example of a prior art circuit system is shown in U.S. Pat. No. 7,199,503, entitled "Energy Saving Driving Circuit for Piezoelectric Motor," which discloses a circuit that can be used to drive two piezoelectric actuators at a voltage higher than the supply voltage, and also to transfer energy from one actuator to the other. However, this circuit uses multiple magnetic elements. Moreover, these elements are inductors, which can limit circuit efficiency in applications where a high voltage step-up ratio is required.

SUMMARY OF THE INVENTION

A circuit is presented that can be used to drive a number of capacitive actuators (or other types of capacitive loads) using only a single magnetic component, while simultaneously generating a drive voltage substantially greater than the power supply voltage. The circuit is especially well suited to systems where two or more actuators are driven in a cyclical manner. The drive circuit is capable of transferring energy from the power supply to any of the actuators, and also of recovering unused energy from certain actuators and transferring it to other actuators, or storing it for use in subsequent actuation cycles. Because the circuit can be applied to a number of capacitive actuators as well as other loads, such as energy storage capacitors, the general term "capacitive load" will be used from now on.

The drive circuit is relevant to any application which involves cyclical energy transfer between two or more capacitive loads. Examples include:

- Piezoelectric positioning systems;
- Piezoelectrically driven optics;
- Piezoelectric fuel injection systems;
- Antagonistic actuators in robotics; and
- Artificial muscle.

A number of switching drive circuits applicable to capacitive loads, and particularly piezoelectric actuators, exist in prior art. To our knowledge, the present drive circuit is the only one capable of recovering energy from multiple capacitive loads using a single magnetic component, while also using the same magnetic component to generate drive voltages that are substantially greater than the power supply voltage. The use of a single magnetic component has the potential to reduce system cost, weight, and dimensions, while maximizing system efficiency by recovering unused energy from the capacitive loads. These qualities make the drive circuit especially attractive for mobile and embedded systems, as well as any weight and power-critical designs.

In a preferred embodiment, the present invention is a circuit for driving a plurality of capacitive actuators. The circuit comprises a low-voltage side, a high voltage side and a flyback transformer between the two. The low-voltage side comprises first and second pairs of low-side switches, with the first pair comprising switches Q_1 and Q_3 connected in series

across the input voltage and the second pair comprising switches Q_2 and Q_4 connected in series across the input voltage, as well as low-side control logic connected to the low-side switches Q_1 , Q_2 , Q_3 and Q_4 for controlling the low-side switches Q_1 , Q_2 , Q_3 and Q_4 . The flyback transformer has a primary winding connected on a first end between the switches Q_1 and Q_3 and connected on a second end between the switches Q_2 and Q_4 . The high-voltage side comprises a switch Q_5 connected between a first end of a secondary winding of the flyback transformer and a ground, a capacitive load C_{A0} , a bidirectional switch Q_{A0} connected in series with the capacitive load C_{A0} . When the bidirectional switch Q_{A0} is closed, the capacitive load C_{A0} is connected between the first end of the secondary winding of the flyback transformer and a ground. The high-voltage side further comprises a switch Q_6 connected between a second end of a secondary winding of the flyback transformer and a ground, a capacitive load C_{B0} and a bidirectional switch Q_{B0} connected in series with the capacitive load C_{B0} . When the bidirectional switch Q_{B0} is closed, the capacitive load C_{B0} is connected between the second end of the secondary winding of the flyback transformer and a ground. The high-voltage side further comprises control logic connected to the switches Q_5 , Q_6 , Q_{A0} and Q_{B0} for controlling the switches Q_5 , Q_6 , Q_{A0} and Q_{B0} . The high-voltage side may further comprise a resistive divider associated with each capacitive load to permit the high side control logic to monitor voltages across the capacitive loads.

The high-voltage side may further comprise an arbitrary number of capacitive loads C_{A1} through C_{AN} and associated switches Q_{A1} through Q_{AN} , connected in the same manner as C_{A0} and Q_{A0} . The high-voltage side may further comprise an arbitrary number of capacitive loads C_{B1} through C_{BN} and associated switches Q_{B1} through Q_{BN} , connected in the same manner as C_{B0} and Q_{B0} . The switches Q_{A1} through Q_{AN} and Q_{B1} through Q_{BN} may be controlled by the high-side control logic.

In another embodiment, the high-voltage side may further comprise a bidirectional switch $Q_{A0'}$ connected in series with the capacitive load C_{A0} and a bidirectional switch $Q_{B0'}$ connected in series with the capacitive load C_{B0} . When the bidirectional switch $Q_{A0'}$ is closed the capacitive load C_{A0} is connected between the second end of the secondary winding of the flyback transformer and a ground. When the bidirectional switch $Q_{B0'}$ is closed the capacitive load C_{B0} is connected between the first end of the secondary winding of the flyback transformer and a ground. The high-voltage side may further comprise an arbitrary number of bidirectional switches $Q_{A1'}$ through $Q_{AN'}$ and $Q_{B1'}$ through $Q_{BN'}$, connected in a similar convention as $Q_{A0'}$ and $Q_{B0'}$, respectively.

In yet another embodiment, the present invention comprises a method for controlling the switches of the circuit to transfer energy from the power supply to any one of a plurality of capacitive loads that may be connected to the circuit and from any one such load to any other such load.

In another preferred embodiment, the present invention is a method for driving multiple capacitive actuators. The method comprises the steps of applying a first voltage V_{ss} across a primary winding of a flyback transformer to store a quantity of energy in a magnetic field of said flyback transformer, disconnecting said first voltage V_{ss} from said primary winding of said flyback transformer, providing a current path from ground to a first capacitive load through the secondary winding of said flyback transformer, delivering energy from said secondary winding of said flyback transformer to said first capacitive load, transferring energy from said first capacitive load to said flyback transformer via the secondary winding of said flyback transformer, providing a current path from

ground to a second capacitive load through said secondary winding of said flyback transformer, delivering energy from said secondary winding of said flyback transformer to said second capacitive load, and repeating the above steps in an appropriate sequence to generate arbitrary voltages that can be substantially higher than said first voltage V_{ss} across said first capacitive load, said second capacitive load, and multiple other capacitive loads as required by the application.

The method may be performed using a circuit having low-side control logic and high-side control logic that generate drive voltages having different phases and waveforms across multiple capacitive loads. The method may further comprise the steps of monitoring the voltages across said capacitive loads, using a first first-in-first-out (FIFO) memory element to record capacitive loads where the voltage must be reduced (i.e. capacitive loads with excess energy), using a second FIFO memory element to record capacitive loads where the voltage must be increased (i.e. capacitive loads requiring energy), initiating an energy transfer from the capacitive load recorded on the output of said first FIFO memory element to the capacitive load recorded on the output of said second FIFO memory element, and subsequently removing the records of said capacitive loads from said FIFO memory elements, initiating an energy transfer from the capacitive load recorded on the output of said first FIFO memory element to an energy storage capacitor when said second FIFO memory element does not contain any entries, and subsequently removing the record of said capacitive load from said first FIFO memory element, initiating an energy transfer from said energy storage capacitor to the capacitive load recorded on the output of said second FIFO memory element when said first FIFO memory element does not contain any entries, and subsequently removing the record of said capacitive load from said second FIFO memory element, and initiating an energy transfer from said input voltage V_{ss} to the capacitive load recorded on the output of said second FIFO memory element when said first FIFO memory element does not contain any entries and when said energy storage capacitor does not contain any energy, and subsequently removing the record of said capacitive load from said second FIFO memory element.

Still other aspects, features, and advantages of the present invention are readily apparent from the following detailed description, simply by illustrating preferable embodiments and implementations. The present invention is also capable of other and different embodiments and its several details can be modified in various obvious respects, all without departing from the spirit and scope of the present invention. Accordingly, the drawings and descriptions are to be regarded as illustrative in nature, and not as restrictive. Additional objects and advantages of the invention will be set forth in part in the description which follows and in part will be obvious from the description, or may be learned by practice of the invention.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

A preferred embodiment of a switching circuit **100** for cyclically driven capacitive loads is shown in FIG. 1. The circuit **100** has a low-voltage side **200** and a high-voltage side **300**. The low-voltage side **200** comprises power supply V_{ss} , switches Q_1 through Q_4 and associated control logic **210**. The high-voltage side **300** comprises switches Q_5 and Q_6 , bidirectional switches Q_{A0} through Q_{AN} and Q_{B0} through Q_{BN} , high-voltage capacitive loads C_{A0} through C_{AN} and C_{B0} through C_{BN} , associated control logic **310**, and a set of resistive dividers **320** to allow control logic **310** to monitor the voltages across the capacitive loads C_{A0} through C_{AN} and C_{B0} through C_{BN} . The low-voltage side **200** and high-voltage side **300** are linked with a flyback transformer **400**, represented by coupled inductances L_P and L_S .

The capacitive loads C_{A0} through C_{AN} and C_{B0} through C_{BN} can represent capacitive actuators (such as piezoelectric, electrostatic, or dielectric elastomer actuators), or energy storage capacitors. These capacitive loads are driven with voltages that can be substantially greater than the voltage provided by power supply V_{ss} . By appropriately modulating the low-side and high-side switches Q , it is possible to use the flyback transformer **400** to transfer energy from the power supply V_{ss} to any of the high-voltage capacitive loads C_A or C_B . The use of a flyback transformer, as opposed to an inductor, can result in increased efficiency in applications where a high voltage step-up ratio is necessary. In a similar manner, it is also possible to transfer energy from any of the loads C_A to any of the loads C_B and vice-versa. If some of the capacitive loads are capacitors used for temporary energy storage, it becomes possible to transfer energy between any two loads C by using the capacitors as an intermediate storage point. In this way, unused electrical energy in the capacitive loads can be recovered and transferred to a different capacitive load, thereby reducing the power consumption of the entire system.

Three examples of energy transfer using the circuit shown in FIG. 1 are shown in FIGS. 2-4. In the cases of energy

6

transfer from the power supply V_{ss} , either switches Q_1 and Q_4 (see FIG. 2A) or switches Q_2 and Q_3 (see FIG. 3A) are closed simultaneously, thereby applying a positive voltage V_{ss} or a negative voltage $-V_{ss}$ across the flyback transformer **400** primary winding L_P . This has the effect of storing a quantity of energy in the magnetic field of the flyback transformer; the quantity depends on the length of time that the switches are closed. Immediately after the low-side switches are opened again, appropriate high-side switches (e.g., Q_{A0} and Q_6 in FIG. 2B and Q_5 and Q_{B0} in FIG. 3B) are closed to provide a current path from ground to the appropriate capacitive load (e.g., load C_{A0} in FIG. 2B and load C_{B0} in FIG. 3B). The collapsing magnetic field in the flyback transformer then induces a current in its secondary winding L_S , which delivers the energy stored in the transformer to the appropriate capacitive load.

In the cases of energy transfer between loads C_A and C_B , the secondary winding L_S of the flyback transformer acts as an inductor. FIGS. 4A and 4B show an exemplary transfer of energy from C_{A0} to C_{B1} . When transferring energy from loads C_{A0} to C_{B1} , the switch Q_6 as well as the appropriate switch Q_A are closed as shown in FIG. 4A, storing energy in the inductor. After some time, switch Q_6 is opened, and immediately thereafter the appropriate switch Q_B is closed as shown in FIG. 4B, delivering the energy to the intended load Q_B . The delivery of energy ends when the appropriate switch Q_B is opened again. The transfer of energy from loads C_B to loads C_A works in a similar fashion, but the roles of switches Q_A and Q_B are reversed, and switch Q_5 is substituted for switch Q_6 .

By transferring known quantities of energy to and from the capacitive loads C , the drive circuit can precisely control the voltage V across each load. During normal circuit operation, the switching cycles similar to the ones shown in FIGS. 2-4 are repeated many times in order to produce the desired voltage waveforms across the loads C . For example, in order to generate a single period of a sinusoidal drive signal across load C_{A0} , the drive circuit may undergo tens to tens of thousands of switching cycles, which may involve energy transfers from power supply as in FIGS. 2A and 2B, as well as energy transfers to and from loads C_{B0} through C_{BN} , such as the one shown in FIGS. 4A and 4B.

In order to generate appropriate timing signals to modulate the switches on both the low-voltage and high-voltage sides, an analog-to-digital converter (ADC) can be used to sample the voltages across the capacitive loads C through resistive dividers, as in FIGS. 1-6. Because the electrical parameters of the capacitive loads and all the circuit components are known, it is possible to use standard circuit theory to compute in advance the lengths of time for which certain switches must be closed to transfer the desired quantity of energy to or from a specific load, for any combination of load voltage sampled by the ADC and the desired (future) value of this voltage. These pre-computed values can be stored in an electronic lookup table and retrieved using the ADC result and a digital value corresponding to the desired load voltage. This method is described in more detail in H. Janocha and C. Stiebel, "New approach to a switching amplifier for piezoelectric actuators," in *Actuator 98*, 1998, pp. 189-192 and M. Karpelson, G.-Y. Wei, and R. J. Wood, "Milligram-scale high-voltage power electronics for piezoelectric microrobots," in *IEEE Int'l Conf. on Robotics and Automation*, 2009, pp. 883-890, and does not constitute a part of the present invention.

The drive circuit is particularly advantageous in cases where capacitive loads are driven 180 degrees out of phase, such as in the case of piezoelectric bimorph actuators and many antagonistic actuator configurations. For each pair of out-of-phase loads, the first is connected to one of the

switches Q_A and the second to one of the switches Q_B . In cases where the loads have different phase offsets or must be driven with different voltage waveforms, energy storage capacitors may be used as one of the loads C_A or C_B to hold the energy recovered from a particular capacitive load if there is no other load ready to accept this energy; the stored energy can then be transferred to another load when it is needed.

In systems with large numbers of capacitive loads operating at different phases and drive voltage waveforms, it can be difficult to determine the optimal way to connect the loads in such a way as to minimize unnecessary energy transfer and reduce the reliance on energy storage capacitors. By introducing additional components to the circuit of FIG. 1, this problem can be greatly simplified.

In the circuit of FIG. 1, each load C can be connected to only one side of the flyback transformer secondary winding L_S , by closing associated switch Q . Introducing additional switches, wherein each load C can be connected, by means of two independent switches (Q and Q'), to either side of the winding L_S , as in FIG. 5, makes it possible to transfer energy from any load C to any other load directly; as a result, it is no longer necessary to decide in advance whether a load should be part of the set C_A or the set C_B .

As described in the previous section, the control logic samples the voltages across the loads using an ADC and resistive dividers. In another preferred embodiment, the control logic can be enhanced as follows: after sampling the voltages across the loads and prior to initiating an energy transfer, the control logic identifies the loads that require energy (termed consumers) and the loads that are available for energy recovery (termed producers). The consumers and producers enter separate first-in-first-out (FIFO) queues. In subsequent switching cycles, energy is transferred from producer to consumer, one at a time, until one of the queues is empty. At that point, if there are entries remaining in the producer queue, the energy is channeled to a storage capacitor. If there are entries remaining in the consumer queue, energy is transferred from the power supply V_{ss} until there are no pending consumers. ADC samples can continue to be read during these switching cycles from loads not immediately involved in energy transfer, so that the control logic remains aware of the state of the system and can refill the producer and consumer queues as necessary. FIG. 6 shows a simplified block diagram and operating algorithms of the associated control architecture. An ADC 610 samples the capacitive load voltages V_L and the samples are stored in memory 620. Command inputs, which instruct a particular capacitive load to be driven to the command voltage V_C , are stored in the command queue 630. To generate a particular voltage waveform across a particular capacitive load, a series of command inputs are issued at discrete time intervals to provide a piecewise approximation of the particular waveform. Retrieval logic 640 iterates through entries in the command queue and determines whether the capacitive load specified in each command input is a producer or a consumer based on the current voltage across the capacitive load. The retrieval logic 640 then enters the capacitive load in the appropriate FIFO queue 650, 660. When both FIFO queues 650, 660 have entries, the switching logic 670 transfers energy from the producer at the output of the producer queue 650 to the consumer at the output of the consumer queue 660. When a producing or consuming capacitive load has reached the voltage specified by its associated command input, it is removed from the FIFO queue 650, 660 where it resides, and the next load in the queue takes its place. When only producers are available, energy is trans-

ferred to a storage capacitor. When only consumers are available, energy is transferred from the supply V_{ss} to the consumers.

This variation on the invention inherently makes the drive circuit more flexible, minimizes unnecessary transfer of energy, and consequently minimizes reliance on energy storage capacitors.

The foregoing description of the preferred embodiment of the invention has been presented for purposes of illustration and description. It is not intended to be exhaustive or to limit the invention to the precise form disclosed, and modifications and variations are possible in light of the above teachings or may be acquired from practice of the invention. The embodiment was chosen and described in order to explain the principles of the invention and its practical application to enable one skilled in the art to utilize the invention in various embodiments as are suited to the particular use contemplated. It is intended that the scope of the invention be defined by the claims appended hereto, and their equivalents. The entirety of each of the aforementioned documents is incorporated by reference herein.

What is claimed is:

1. A circuit for driving a plurality of capacitive actuators, comprising:

a low-voltage side comprising:

first and second pairs of low-side switches, said first pair of comprising switches Q_1 and Q_3 connected in series across said input voltage and said second pair comprising switches Q_2 and Q_4 connected in series across said input voltage;

low-side control logic connected to said low-side switches Q_1 , Q_2 , Q_3 and Q_4 for controlling said low-side switches Q_1 , Q_2 , Q_3 and Q_4 ; and

a flyback transformer having a primary winding connected on a first end between said switches Q_1 and Q_3 and connected on a second end between said switches Q_2 and Q_4 ;

a high-voltage side comprising:

a switch Q_5 connected between a first end of a secondary winding of said flyback transformer and a ground;

a capacitive load C_{A0} ;

a bidirectional switch Q_{A0} connected in series with said capacitive load C_{A0} , wherein when said bidirectional switch Q_{A0} is closed said capacitive load C_{A0} is connected between said first end of said secondary winding of said flyback transformer and a ground;

a switch Q_6 connected between a second end of a secondary winding of said flyback transformer and a ground;

a capacitive load C_{B0} ; and

a bidirectional switch Q_{B0} connected in series with said capacitive load C_{B0} , wherein when said bidirectional switch Q_{B0} is closed said capacitive load C_{B0} is connected between said second end of said secondary winding of said flyback transformer and a ground;

high-side control logic connected to said switches Q_5 , Q_6 , Q_{A0} and Q_{B0} for controlling said switches Q_5 , Q_6 , Q_{A0} and Q_{B0} .

2. A circuit according to claim 1, further comprising a resistive divider associated with each capacitive load to permit said high side control logic to monitor voltages across said capacitive loads.

3. A circuit according to claim 1, said high-voltage side further comprising:

a plurality of capacitive loads C_{A1} through C_{AN} and bidirectional switches Q_{A1} through Q_{AN} , connected in the same manner as C_{A0} and Q_{A0} ; and

9

a plurality of capacitive loads C_{B1} through C_{BN} and bidirectional switches Q_{B1} through Q_{BN} , connected in the same manner as C_{B0} and Q_{B0} ;

wherein said switches Q_{A0} through Q_{AN} and Q_{B0} through Q_{BN} are controlled by said high-side control logic.

4. A circuit according to claim 3, wherein said high-voltage side further comprises:

a bidirectional switch Q_{A0} , connected in series with said capacitive load C_{A0} , wherein when said bidirectional switch Q_{A0} is closed said capacitive load C_{A0} is connected between said second end of said secondary winding of said flyback transformer and a ground;

a bidirectional switch Q_{B0} , connected in series with said capacitive load C_{B0} , wherein when said bidirectional switch Q_{B0} is closed said capacitive load C_{B0} is connected between said first end of said secondary winding of said flyback transformer and a ground;

a plurality of bidirectional switches Q_{A1} through Q_{AN} , connected in the same manner as Q_{A0} ; and

a plurality of bidirectional switches Q_{B1} through Q_{BN} , connected in the same manner as Q_{B0} ;

wherein said switches Q_{A0} through Q_{AN} and Q_{B0} through Q_{BN} are controlled by said high-side control logic.

5. A circuit according to claim 2, said high-voltage side further comprising:

a plurality of capacitive loads C_{A1} through C_{AN} and bidirectional switches Q_{A1} through Q_{AN} , connected in the same manner as C_{A0} and Q_{A0} ; and

a plurality of capacitive loads C_{B1} through C_{BN} and bidirectional switches Q_{B1} through Q_{BN} , connected in the same manner as C_{B0} and Q_{B0} ;

wherein said switches Q_{A0} through Q_{AN} and Q_{B0} through Q_{BN} are controlled by said high-side control logic.

6. A circuit according to claim 5, wherein said high-voltage side further comprises:

a bidirectional switch Q_{A0} , connected in series with said capacitive load C_{A0} , wherein when said bidirectional switch Q_{A0} is closed said capacitive load C_{A0} is connected between said second end of said secondary winding of said flyback transformer and a ground;

a bidirectional switch Q_{B0} , connected in series with said capacitive load C_{B0} , wherein when said bidirectional switch Q_{B0} is closed said capacitive load C_{B0} is connected between said first end of said secondary winding of said flyback transformer and a ground;

a plurality of bidirectional switches Q_{A1} through Q_{AN} , connected in the same manner as Q_{A0} ; and

a plurality of bidirectional switches Q_{B1} through Q_{BN} , connected in the same manner as Q_{B0} ;

wherein said switches Q_{A0} through Q_{AN} and Q_{B0} through Q_{BN} are controlled by said high-side control logic.

7. A method for driving multiple capacitive actuators comprising the steps of:

applying a first voltage V_{ss} across a primary winding of a flyback transformer to store a quantity of energy in a magnetic field of said flyback transformer;

disconnecting said first voltage V_{ss} from said primary winding of said flyback transformer;

10

providing a current path from ground to a first capacitive load through the secondary winding of said flyback transformer;

delivering energy from said secondary winding of said flyback transformer to said first capacitive load;

transferring energy from said first capacitive load to said flyback transformer via the secondary winding of said flyback transformer;

providing a current path from ground to a second capacitive load through said secondary winding of said flyback transformer;

delivering energy from said secondary winding of said flyback transformer to said second capacitive load; and

repeating the above steps in an appropriate sequence to generate arbitrary voltages that can be substantially higher than said first voltage V_{ss} across said first capacitive load, said second capacitive load, and multiple other capacitive loads as required by the application.

8. The method according to claim 7, wherein low-side control logic and high-side control logic generate drive voltages having different phases and waveforms across multiple capacitive loads by repeating the following steps:

monitoring voltages across said multiple capacitive loads; tracking command inputs that instruct certain capacitive loads to be driven to certain voltages, as required by system operation;

using a first first-in-first-out (FIFO) memory element to record capacitive loads where the voltage must be reduced;

using a second FIFO memory element to record capacitive loads where the voltage must be increased;

initiating an energy transfer from the capacitive load recorded on the output of said first FIFO memory element to a capacitive load recorded on an output of said second FIFO memory element;

removing a record of a capacitive load from the FIFO queue where it is stored once said capacitive load has reached the voltage indicated by the command input;

initiating an energy transfer from the capacitive load recorded on the output of said first FIFO memory element to an energy storage capacitor when said second FIFO memory element does not contain any entries, and subsequently removing the record of said capacitive load from said first FIFO memory element;

initiating an energy transfer from said energy storage capacitor to the capacitive load recorded on the output of said second FIFO memory element when said first FIFO memory element does not contain any entries, and subsequently removing the record of said capacitive load from said second FIFO memory element; and

initiating an energy transfer from said input voltage V_{ss} to the capacitive load recorded on the output of said second FIFO memory element when said first FIFO memory element does not contain any entries and when said energy storage capacitor does not contain any energy, and subsequently removing the record of said capacitive load from said second FIFO memory element.
