(57) **ABSTRACT**

Disclosed are various embodiments for performing stateless verification of communication addresses. Encrypted verification data is generated for a user account, including a communication address and a first verification code, and a timestamp. The encrypted verification data is sent to a client, and the verification code is transmitted to the communication address. The encrypted verification data and a second verification code are received from the client. The communication address is verified in response to observing that the first verification code from the encrypted verification data matches the second verification code.

FIG. 2B

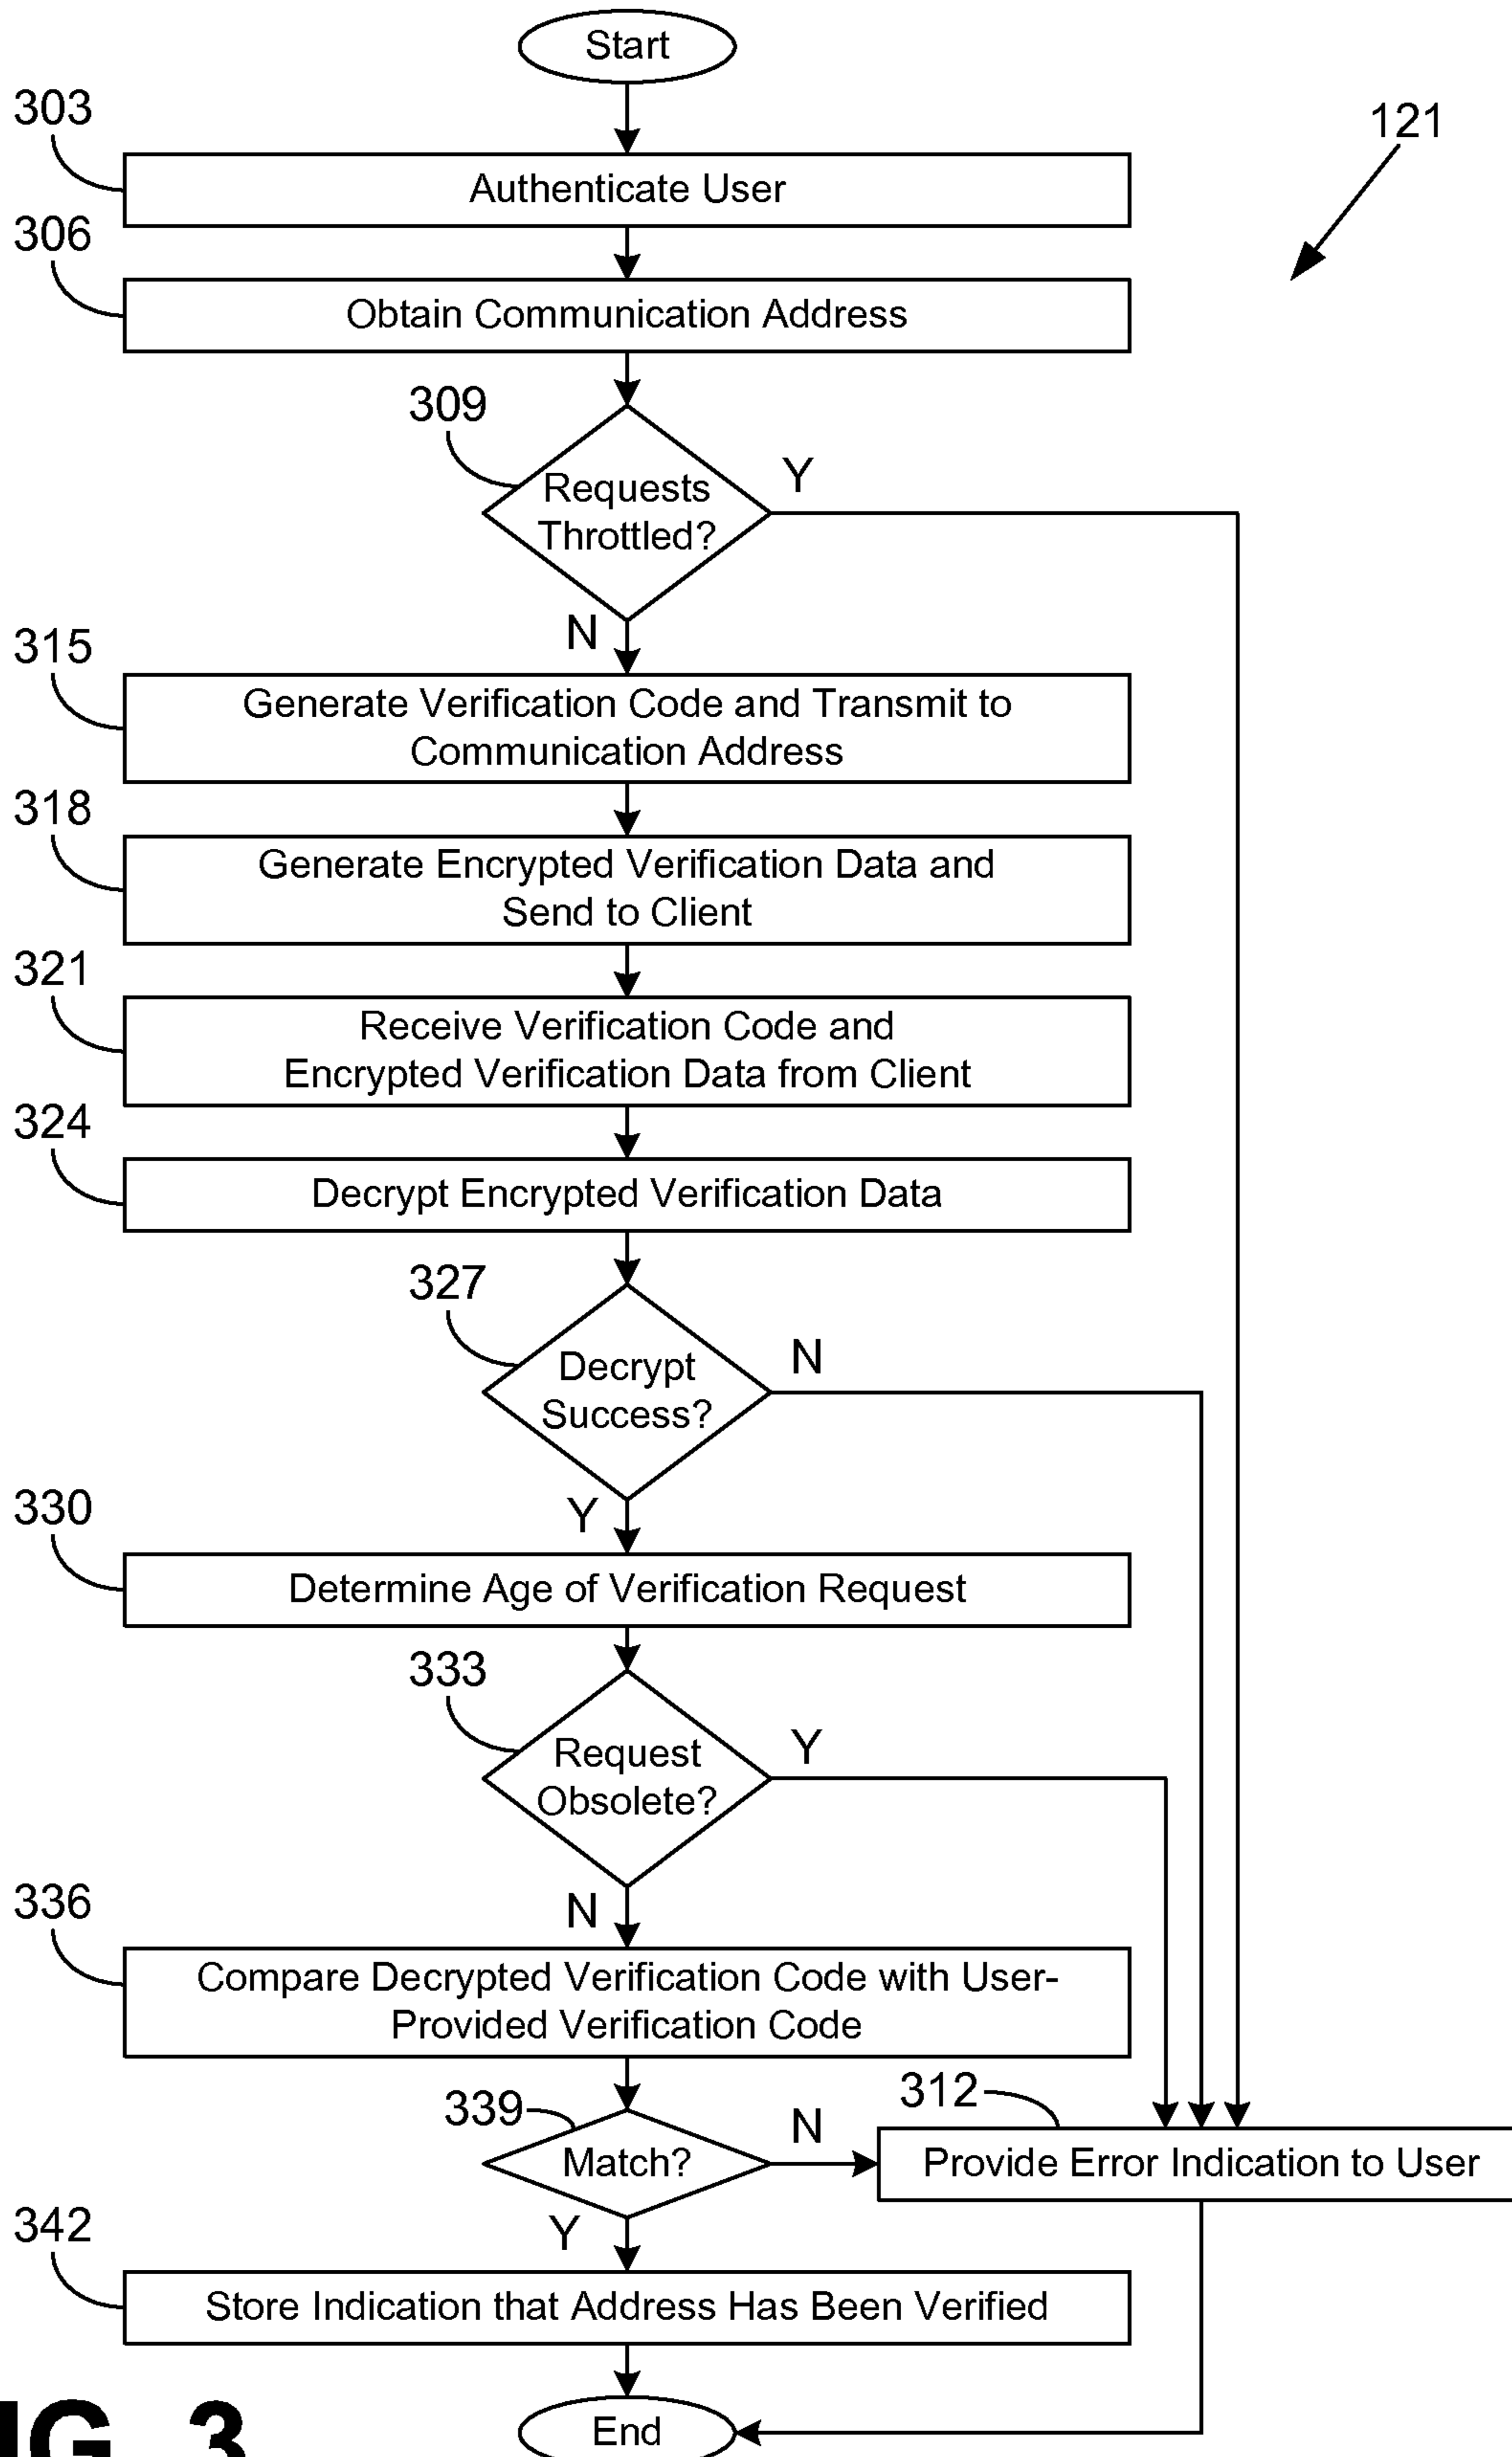

FIG. 3

FIG. 4

1**VERIFICATION OF USER
COMMUNICATION ADDRESSES****CROSS-REFERENCE TO RELATED
APPLICATIONS**

This application is a continuation of co-pending U.S. utility application entitled "VERIFICATION OF USER COMMUNICATION ADDRESSES," having Ser. No. 13/490,972, and filed Jun. 7, 2012, which is incorporated herein by reference in its entirety.

BACKGROUND

An online retailer or other entity may communicate with its customers by various communication channels. For example, the online retailer may originate short message service (SMS) messages to a mobile telephone number of the customer, voice calls to a telephone number of the customer, email messages to an email address of the customer, printed materials to a postal address of the customer, and so on. Without verification that the telephone numbers, email addresses, postal addresses, and/or other addresses have been accurately provided for the customer, notifications or other significant communications intended for the customer may be lost or misdirected.

BRIEF DESCRIPTION OF THE DRAWINGS

Many aspects of the present disclosure can be better understood with reference to the following drawings. The components in the drawings are not necessarily to scale, emphasis instead being placed upon clearly illustrating the principles of the disclosure. Moreover, in the drawings, like reference numerals designate corresponding parts throughout the several views.

FIG. 1 is a drawing of a networked environment according to various embodiments of the present disclosure.

FIGS. 2A and 2B are drawings of example user interfaces rendered by a client in the networked environment of FIG. 1 according to various embodiments of the present disclosure.

FIG. 3 is a flowchart illustrating one example of functionality implemented as portions of verification application executed in a computing environment in the networked environment of FIG. 1 according to various embodiments of the present disclosure.

FIG. 4 is a schematic block diagram that provides one example illustration of a computing environment employed in the networked environment of FIG. 1 according to various embodiments of the present disclosure.

DETAILED DESCRIPTION

The present disclosure relates to a stateless verification of communication addresses provided by users. An online retailer or other entity may request communication addresses from users. Such communication addresses may, for example, include phone numbers, email addresses, postal addresses, and so on. Verification is performed to determine that the provided communication address is legitimate and that communication to the user may be performed by way of the communication address. In a sense, ownership by the user of the communication address is established through the verification.

To perform the verification, a verification code is typically sent to the communication address, and the user confirms ownership of the communication address by providing the

2

verification code. A naïve implementation of such a system may involve temporarily storing the verification code and other data at the server in association with the communication address in order for the server to determine whether the communication address is valid. However, such an implementation may result in the storage of a large quantity of temporary data, including data for communication addresses that may never be verified. Also, stale data may need to be periodically cleared, which involves processing resources.

Various embodiments of the present disclosure provide verification of user-provided communication addresses without the need for temporary storage of verification codes or other data at the server side. To this end, encrypted data is provided to a client in response to a communication address being provided. The encrypted data includes the data involved in carrying out the verification. A verification code is transmitted to the communication address. Subsequently, the user provides the verification code and the encrypted data to a server. The server then verifies the communication address based at least in part on the verification code and the encrypted data. The encrypted data need not be persisted in the server, which conserves data storage and processing resources. In the following discussion, a general description of the system and its components is provided, followed by a discussion of the operation of the same.

With reference to FIG. 1, shown is a networked environment **100** according to various embodiments. The networked environment **100** includes a computing environment **103** in data communication with one or more clients **106** by way of a network **109**. The network **109** includes, for example, the Internet, intranets, extranets, wide area networks (WANs), local area networks (LANs), wired networks, wireless networks, or other suitable networks, etc., or any combination of two or more such networks. The computing environment **103** may also be capable of transmitting a notification to a communication client **112** by way of the network **109**. The communication client **112** may correspond to a telephone, smartphone, feature phone, a desktop computer, a laptop computer, personal digital assistants, set-top boxes, music players, web pads, tablet computer systems, game consoles, electronic book readers, or other devices with like capability.

The computing environment **103** may comprise, for example, a server computer or any other system providing computing capability. Alternatively, a plurality of computing devices may be employed that are arranged, for example, in one or more server banks or computer banks or other arrangements. For example, a plurality of computing devices together may comprise a cloud computing resource, a grid computing resource, and/or any other distributed computing arrangement. Such computing devices may be located in a single installation or may be distributed among many different geographical locations.

Various applications and/or other functionality may be executed in the computing environment **103** according to various embodiments. Also, various data is stored in a data store **115** that is accessible to the computing environment **103**. The data store **115** may be representative of a plurality of data stores **115** as can be appreciated. The data stored in the data store **115**, for example, is associated with the operation of the various applications and/or functional entities described below.

The components executed on the computing environment **103**, for example, include a network data server **118**, a verification application **121**, an encryption provider **124**, a verification code generator **127**, and other applications, services, processes, systems, engines, or functionality not discussed in detail herein. The network data server **118** is executed to serve

up network pages and/or other forms of network data to the clients **106** by way of the network **109**. The network pages may include, for example, web pages, mobile application screens, gopher pages, and/or other forms of network data. The network data server **118** may include a commercially available hypertext transfer protocol (HTTP) server such as, for example, Apache® HTTP Server, Apache® Tomcat®, Microsoft® Internet Information Services (IIS), and so on.

The verification application **121** is executed to generate network pages and/or other data to facilitate receiving and verifying communication addresses for users. Upon receiving a verification request from an authenticated user, the verification application **121** generates network data **130**, which includes encrypted verification data **133**. The encrypted verification data **133** includes, for example, the communication address **136**, the verification code **139**, the user identifier **142** for the user, and a timestamp **145** for ensuring timeliness of the verification with respect to the verification request.

The encrypted verification data **133** is sent to the client **106** by way of the network **109**. The verification application **121** is also configured to transmit the verification code **139** to a communication client **112** at the communication address as part of the verification process. From the client **106**, the verification application **121** receives network data **148**, which includes the encrypted verification data **133** previously sent to the client **106** and the verification code **139** previously transmitted to the communication client **112**.

The encryption provider **124** is configured to encrypt and decrypt the encrypted verification data **133**. The encryption provided by the encryption provider **124** may be relied upon to prevent the user from gaining access to or modifying the contents of the encrypted verification data **133**. The verification code generator **127** is configured to generate the verification code **139** from stored data or an algorithmic approach.

The data stored in the data store **115** includes, for example, network page data **151**, user data **154**, verification code generation data **157**, secret keys **160**, and potentially other data. The network page data **151** may include code, text, templates, images, graphics, video, audio, animations, and/or other data used in generating network pages to be served up by the network data server **118**. The user data **154** includes data associated with users of the system. In one example, the users may be registered customers or prospective customers of an online retailer.

The user data **154** may include, for example, user identifiers **163**, security credentials **166**, verified communication addresses **169**, and/or other data. A user identifier **163** may correspond to a unique identifier for a user. The security credentials **166** may include, for example, usernames, passwords, security questions and responses, keys, and/or other credentials that may be employed to authenticate a user. The verified communication addresses **169** include communication addresses which have previously been verified for the user.

The verification code generation data **157** includes data that may be used by the verification code generator **127** in generating a verification code **139** for a given communication address verification request. To this end, the verification code generation data **157** may correspond to a dictionary of words or phrases that may be modified or used directly for a verification code **139**. Alternatively, the verification code generator **127** may be configured to generate the verification code **139** through a random or other algorithmic process. However, words or phrases may be easier to remember or enter by the user.

The secret keys **160** correspond to keys that may be used by the encryption provider **124** to encrypt or decrypt the

encrypted verification data **133**. The secret keys **160** may correspond to symmetric keys or asymmetric keys. However, it is noted that the user is not given access to the secret keys **160**.

The client **106** is representative of a plurality of client devices that may be coupled to the network **109**. The client **106** may comprise, for example, a processor-based system such as a computer system. Such a computer system may be embodied in the form of a desktop computer, a laptop computer, personal digital assistants, cellular telephones, smart-phones, set-top boxes, music players, web pads, tablet computer systems, game consoles, electronic book readers, or other devices with like capability. The client **106** may include a display **172**. The display **172** may comprise, for example, one or more devices such as cathode ray tubes (CRTs), liquid crystal display (LCD) screens, gas plasma-based flat panel displays, LCD projectors, or other types of display devices, etc.

The client **106** may be configured to execute various applications such as a browser **175** and/or other applications. The browser **175** may be executed in a client **106**, for example, to access and render network pages, such as web pages, or other network content served up by the computing environment **103** and/or other servers, thereby generating a rendered network page **178** on the display **172**. The browser **175** may also be configured to store cookies **181** set by the computing environment **103**. The client **106** may be configured to execute applications beyond the browser **175** such as, for example, mobile applications, email applications, instant message applications, and/or other applications.

Next, a general description of the operation of the various components of the networked environment **100** is provided. To begin, a user is authenticated by the verification application **121** by providing a security credential **166** or enrolling as a new user. The user provides one or more communication addresses **136** to the verification application **121**. For example, the user may enter a control panel network page or mobile application screen and specify a new telephone number, email address, postal address, etc. to be associated with the account of the user. In one embodiment, the communication address **136** may be preliminarily verified not to belong to another user in the verified communication addresses **169**.

The frequency or absolute number of address verification requests by a particular user may be throttled to prevent abuse of the system. For example, the verification application **121** may keep a counter for outstanding address verification requests for the user. In some cases, a timestamp or other tracking data may be persisted in the data store **115** to prevent rapid request origination.

In response to receiving a new, unverified communication address, the verification application **121** generates encrypted verification data **133**. To this end, the verification application **121** receives the communication address **136** and the user identifier **142** for the user. The verification application **121** generates a verification code **139** with the verification code generator **127**. The verification application **121** also generates a current timestamp **145**. The data including the communication address **136**, the verification code **139**, the user identifier **142**, and the timestamp **145** are encrypted into one or more “blobs” by the encryption provider **124** using the secret keys **160** to produce the encrypted verification data **133**. It is noted that the computing environment **103** does not persist an association of the communication address **136** with the verification code **139** in memory before the communication address **136** is verified.

In addition, the verification application **121** transmits the verification code **139** to the communication client **112** at the

5

communication address **136**. To this end, the verification application **121** may send an email message or text message containing the verification code **139**. A text message may be relayed, for example, to a telephone number by a text gateway on the network **109**.

In some cases, the communication address **136** may not define a network-reachable communication client **112**. As an example, where the communication address **136** is a telephone number, the verification application **121** may place a voice call on the public switched telephone network to the telephone number, where the verification code **139** will be provided during the voice call. As another example, where the communication address **136** is a postal address, the verification application **121** may initiate the generation of materials to be sent by mail to the postal address, where the materials include the verification code **139**.

The encrypted verification data **133** is provided by the verification application **121** to the client **106** in the network data **130**. The communication client **112** may correspond to the client **106** in some situations. In one embodiment, the verification application **121** may cause the network data server **118** to set a cookie **181** in the browser **175**, where the cookie **181** includes the encrypted verification data **133**. In another embodiment, the verification application **121** may generate a network page that includes a form. The form may include a prepopulated field that includes the encrypted verification data **133**. This prepopulated field may correspond to a hidden field or a user-visible field as desired. The form may be configured to obtain the verification code **139** as received by the user.

Next, the user at the client **106** provides the verification code **139** received through the communication address **136** via a form in the rendered network page **178**. Upon submitting the form, the network data **148** is sent to the network data server **118** and on to the verification application **121**. The network data **148** includes the encrypted verification data **133** in the form submission or as a cookie **181**. The network data **148** also includes the verification code **139** entered by the user, e.g., into a text-input field, or selected via a drop-down box, a radio button, a check box, or other user interface components.

Upon receiving the network data **148**, the verification application **121** begins performing the verification of the communication address **136**. To this end, the verification application **121** uses the encryption provider **124** to decrypt the encrypted verification data **133**. If the encrypted verification data **133** is not present or able to be decrypted, the communication address **136** is not verified. If the contents of the encrypted verification data **133** are successfully extracted, the verification application **121** compares the verification code **139** from the encrypted verification data **133** as a reference against the verification code **139** supplied by the user. If they do not match, the communication address **136** is not verified.

Also, the verification application **121** evaluates the timestamp **145** with respect to a maximum age threshold relative to the current time. It may be desirable to have the verification request have only a brief lifetime, e.g., 30 minutes, an hour, a day, a week, etc. Such a lifetime may be established based on the type of communication address **136** and/or on other factors. Verifying a postal address, for example, may involve a week or more as the request lifetime for the request to allow for delivery and receipt at the postal address. By contrast, a text message may be received near instantaneously, which may weigh towards a lifetime of 30 minutes or less. If the timestamp **145** is too old, the communication address **136** is not verified.

6

If the maximum age criteria are met and the verification codes **139** match, the communication address **136** may be considered verified. Accordingly, the communication address **136** may be associated with the user identifier **142** in the user data **154** as a verified communication address **169**.

Referring next to FIG. 2A, shown is an exemplary user interface **200** rendered in the browser **175** (FIG. 1) executed in the client **106** (FIG. 1) in the networked environment **100** (FIG. 1) according to an embodiment. The user interface **200** includes a rendered network page **178a** which allows an authenticated user to specify a communication address **136** (FIG. 1) (in particular, an email address) for verification.

In this non-limiting example, a user indication **203** shows that a user named "Fred Simpson" is currently logged in. In other examples, a user may provide security credentials **166** (FIG. 1) concurrently with a new communication address **136**. An address input field **206** is provided for the user to input a new email address for verification. A submit component **209** may be provided for the user to submit the new email address to the server for verification. In other embodiments, a user may select from previously stored communication addresses **136**. If only one communication address **136** is available for verification, the user may merely submit a verification request, which in turn implicitly indicates a stored communication address **136** to be verified.

Moving on to FIG. 2B, shown is an exemplary user interface **220** rendered in the browser **175** (FIG. 1) executed in the client **106** (FIG. 1) in the networked environment **100** (FIG. 1) according to an embodiment. The user interface **220** includes a rendered network page **178b** which allows an authenticated user to enter a verification code **139** (FIG. 1) that has been sent to the email address provided in the user interface **200** (FIG. 2A).

The rendered network page **178b** includes an explanation **223** that an email message has been sent to the provided email address, which in this example is "fred@company.site." The rendered network page **178b** also includes a verification code input field **226** for the user to input the verification code **139**. The explanation **223** further includes instructions in this regard. The form depicted in FIG. 2B may also include a hidden field having the encrypted verification data **133** (FIG. 1). A submit component **228** may be provided for the user to submit the verification code **139** input by the user along with the encrypted verification data **133**. In another example, the encrypted verification data **133** may be provided along with the form as a cookie **181** (FIG. 1).

Referring next to FIG. 3, shown is a flowchart that provides one example of the operation of a portion of the verification application **121** according to various embodiments. It is understood that the flowchart of FIG. 3 provides merely an example of the many different types of functional arrangements that may be employed to implement the operation of the portion of the verification application **121** as described herein. As an alternative, the flowchart of FIG. 3 may be viewed as depicting an example of steps of a method implemented in the computing environment **103** (FIG. 1) according to one or more embodiments.

Beginning with box **303**, the verification application **121** authenticates a user at a client **106** (FIG. 1). Alternatively, the user may be a new user who is establishing an account via an enrollment process. In box **306**, the verification application **121** receives a communication address **136** (FIG. 1) from the user by way of the client **106**. In some cases, multiple communication addresses **136** may be received at once from the user. In other embodiments, the verification application **121** may obtain one or more previously stored communication addresses **136** that may be associated with the user. In box

309, the verification application 121 determines whether the verification requests by the user (or from the client 106) have been throttled for being excessive. If the requests have been throttled for being excessive, the verification application 121 proceeds to box 312 and provides an error indication to the user. Thereafter, the portion of the verification application 121 ends.

If the verification application 121 determines that the verification requests of the user have not been throttled, the verification application 121 proceeds from box 309 to box 315. In box 315, the verification application 121 generates the verification code 139 (FIG. 1) using the verification code generator 127 (FIG. 1) and transmits the verification code 139 to the communication address 136 provided by the user in box 306. The encrypted verification data 133 (FIG. 1) may be encrypted by the encryption provider 124 (FIG. 1) using the secret keys 160 (FIG. 1). In box 318, the verification application 121 generates encrypted verification data 133 and sends it to the client 106. The encrypted verification data 133 may, for example, be set as a cookie 181 (FIG. 1) or encoded in a form in a network page.

In box 321, the verification application 121 receives the verification code 139 as input by the user and the encrypted verification data 133 from the client 106. In box 324, the verification application 121 decrypts the encrypted verification data 133 provided by the client 106 using the encryption provider 124, which uses the secret keys 160. In box 327, the verification application 121 determines whether the decryption has been successful. If the decryption was not successful, the verification application 121 proceeds to box 312 and provides an error indication to the user. Thereafter, the portion of the verification application 121 ends.

If the decryption was successful, the verification application 121 moves from box 327 to box 330. In box 330, the verification application 121 determines the age of the verification request using the decrypted timestamp 145 (FIG. 1). In box 333, the verification application 121 determines whether the request is obsolete with reference to a maximum age threshold. If the request is obsolete, the verification application 121 proceeds to box 312 and provides an error indication to the user. Thereafter, the portion of the verification application 121 ends.

If the request is not obsolete, the verification application 121 continues from box 333 to box 336. In box 336, the verification application 121 compares the decrypted verification code 139 with the user-provided verification code 139. In box 339, the verification application 121 determines whether the decrypted verification code 139 matches the user-provided verification code 139. If they do not match, the verification application 121 proceeds to box 312 and provides an error indication to the user. Thereafter, the portion of the verification application 121 ends.

If they do match, the verification application 121 moves from box 339 to box 342. In box 342, the verification application 121 stores an indication in the data store 115 (FIG. 1) that the communication address 136 has been verified. For example, the verification application 121 may associate the decrypted communication address 136 with the decrypted user identifier 142 (FIG. 1) in the data store 115. To this end, the communication address 136 may be added to the verified communication addresses 169 (FIG. 1) for the user. Alternatively, where the communication address 136 is already associated with the user identifier 142 in the data store 115, the verification application 121 may, for example, update a status in the data store 115 that indicates that the previously associated communication address 136 has been verified.

In one embodiment, the computing environment 103 may give the user access to some secured resource only after the user has verified the communication address 136. In such a case, a second factor authentication token may then be provided to the client 106 to provide access to the secured resource. In another embodiment, the address verification process may be used to confirm an on-line transaction. Thereafter, the portion of the verification application 121 ends.

With reference to FIG. 4, shown is a schematic block diagram of the computing environment 103 according to an embodiment of the present disclosure. The computing environment 103 comprises one or more computing devices 400. The computing device 400 includes at least one processor circuit, for example, having a processor 403 and a memory 406, both of which are coupled to a local interface 409. To this end, the computing device 400 may comprise, for example, at least one server computer or like device. The local interface 409 may comprise, for example, a data bus with an accompanying address/control bus or other bus structure as can be appreciated.

Stored in the memory 406 are both data and several components that are executable by the processor 403. In particular, stored in the memory 406 and executable by the processor 403 are the network data server 118, the verification application 121, the encryption provider 124, the verification code generator 127, and potentially other applications. Also stored in the memory 406 may be a data store 115 and other data. In addition, an operating system may be stored in the memory 406 and executable by the processor 403.

It is understood that there may be other applications that are stored in the memory 406 and are executable by the processor 403 as can be appreciated. Where any component discussed herein is implemented in the form of software, any one of a number of programming languages may be employed such as, for example, C, C++, C#, Objective C, Java®, JavaScript®, Perl, PHP, Visual Basic®, Python®, Ruby, Delphi®, Flash®, or other programming languages.

A number of software components are stored in the memory 406 and are executable by the processor 403. In this respect, the term “executable” means a program file that is in a form that can ultimately be run by the processor 403. Examples of executable programs may be, for example, a compiled program that can be translated into machine code in a format that can be loaded into a random access portion of the memory 406 and run by the processor 403, source code that may be expressed in proper format such as object code that is capable of being loaded into a random access portion of the memory 406 and executed by the processor 403, or source code that may be interpreted by another executable program to generate instructions in a random access portion of the memory 406 to be executed by the processor 403, etc. An executable program may be stored in any portion or component of the memory 406 including, for example, random access memory (RAM), read-only memory (ROM), hard drive, solid-state drive, USB flash drive, memory card, optical disc such as compact disc (CD) or digital versatile disc (DVD), floppy disk, magnetic tape, or other memory components.

The memory 406 is defined herein as including both volatile and nonvolatile memory and data storage components. Volatile components are those that do not retain data values upon loss of power. Nonvolatile components are those that retain data upon a loss of power. Thus, the memory 406 may comprise, for example, random access memory (RAM), read-only memory (ROM), hard disk drives, solid-state drives, USB flash drives, memory cards accessed via a memory card reader, floppy disks accessed via an associated floppy disk

drive, optical discs accessed via an optical disc drive, magnetic tapes accessed via an appropriate tape drive, and/or other memory components, or a combination of any two or more of these memory components. In addition, the RAM may comprise, for example, static random access memory (SRAM), dynamic random access memory (DRAM), or magnetic random access memory (MRAM) and other such devices. The ROM may comprise, for example, a programmable read-only memory (PROM), an erasable programmable read-only memory (EPROM), an electrically erasable programmable read-only memory (EEPROM), or other like memory device.

Also, the processor 403 may represent multiple processors 403 and the memory 406 may represent multiple memories 406 that operate in parallel processing circuits, respectively. In such a case, the local interface 409 may be an appropriate network that facilitates communication between any two of the multiple processors 403, between any processor 403 and any of the memories 406, or between any two of the memories 406, etc. The local interface 409 may comprise additional systems designed to coordinate this communication, including, for example, performing load balancing. The processor 403 may be of electrical or of some other available construction.

Although the network data server 118, the verification application 121, the encryption provider 124, the verification code generator 127, and other various systems described herein may be embodied in software or code executed by general purpose hardware as discussed above, as an alternative the same may also be embodied in dedicated hardware or a combination of software/general purpose hardware and dedicated hardware. If embodied in dedicated hardware, each can be implemented as a circuit or state machine that employs any one of or a combination of a number of technologies. These technologies may include, but are not limited to, discrete logic circuits having logic gates for implementing various logic functions upon an application of one or more data signals, application specific integrated circuits having appropriate logic gates, or other components, etc. Such technologies are generally well known by those skilled in the art and, consequently, are not described in detail herein.

The flowchart of FIG. 3 shows the functionality and operation of an implementation of portions of the verification application 121. If embodied in software, each block may represent a module, segment, or portion of code that comprises program instructions to implement the specified logical function(s). The program instructions may be embodied in the form of source code that comprises human-readable statements written in a programming language or machine code that comprises numerical instructions recognizable by a suitable execution system such as a processor 403 in a computer system or other system. The machine code may be converted from the source code, etc. If embodied in hardware, each block may represent a circuit or a number of interconnected circuits to implement the specified logical function(s).

Although the flowchart of FIG. 3 shows a specific order of execution, it is understood that the order of execution may differ from that which is depicted. For example, the order of execution of two or more blocks may be scrambled relative to the order shown. Also, two or more blocks shown in succession in FIG. 3 may be executed concurrently or with partial concurrence. Further, in some embodiments, one or more of the blocks shown in FIG. 3 may be skipped or omitted. In addition, any number of counters, state variables, warning semaphores, or messages might be added to the logical flow described herein, for purposes of enhanced utility, accounting, performance measurement, or providing troubleshooting

aids, etc. It is understood that all such variations are within the scope of the present disclosure.

Also, any logic or application described herein, including the network data server 118, the verification application 121, the encryption provider 124, and the verification code generator 127, that comprises software or code can be embodied in any non-transitory computer-readable medium for use by or in connection with an instruction execution system such as, for example, a processor 403 in a computer system or other system. In this sense, the logic may comprise, for example, statements including instructions and declarations that can be fetched from the computer-readable medium and executed by the instruction execution system. In the context of the present disclosure, a "computer-readable medium" can be any medium that can contain, store, or maintain the logic or application described herein for use by or in connection with the instruction execution system.

The computer-readable medium can comprise any one of many physical media such as, for example, magnetic, optical, or semiconductor media. More specific examples of a suitable computer-readable medium would include, but are not limited to, magnetic tapes, magnetic floppy diskettes, magnetic hard drives, memory cards, solid-state drives, USB flash drives, or optical discs. Also, the computer-readable medium may be a random access memory (RAM) including, for example, static random access memory (SRAM) and dynamic random access memory (DRAM), or magnetic random access memory (MRAM). In addition, the computer-readable medium may be a read-only memory (ROM), a programmable read-only memory (PROM), an erasable programmable read-only memory (EPROM), an electrically erasable programmable read-only memory (EEPROM), or other type of memory device.

It should be emphasized that the above-described embodiments of the present disclosure are merely possible examples of implementations set forth for a clear understanding of the principles of the disclosure. Many variations and modifications may be made to the above-described embodiment(s) without departing substantially from the spirit and principles of the disclosure. All such modifications and variations are intended to be included herein within the scope of this disclosure and protected by the following claims.

The invention claimed is:

1. A non-transitory computer-readable medium embodying a program executable in at least one computing device, the program configured to perform a stateless verification by the at least one computing device that a user of a client has access to a communication address, wherein when executed the program causes the at least one computing device to at least:
 - generate encrypted verification data for a user account, the encrypted verification data including a first verification code and the communication address associated with the user of the client;
 - send the encrypted verification data to the client using a first network and a first communication protocol;
 - transmit a second verification code to the communication address using a second network and a second communication protocol; and
 - in response to receiving from the client via the first communication protocol the encrypted verification data and the transmitted second verification code received by the communication address, verify that the second verification code was received by the communication address by decrypting the received verification data, retrieving the sent first verification code from the decrypted verification data, and observing that the retrieved first verification

11

tion code matches the second verification code received by the at least one computing device.

2. The non-transitory computer-readable medium of claim 1, wherein the first verification code is unavailable in encrypted form to the client.

3. The non-transitory computer-readable medium of claim 1, wherein the at least one computing device is configured not to persist the first verification code or the second verification code in data storage.

4. The non-transitory computer-readable medium of claim 1, wherein when executed the program further causes the at least one computing device to authenticate the client for access to the user account before sending the encrypted verification data to the client.

5. The non-transitory computer-readable medium of claim 1, wherein the encrypted verification data further comprises a timestamp, and wherein when executed the program further causes the at least one computing device to, in response to retrieving the timestamp from the decrypted verification data, determine that an age of the retrieved timestamp is less than a maximum threshold age.

6. The non-transitory computer-readable medium of claim 1, wherein when executed the program further causes the at least one computing device to determine that the client has not performed a maximum number of communication address verifications.

7. A system for performing a stateless verification that a user of a client has access to a communication address, the system comprising:

at least one computing device; and

at least one application executed in the at least one computing device, wherein when executed the at least one application causes the at least one computing device to at least:

generate encrypted verification data for a user account, the encrypted verification data including a first verification code and the communication address associated with the user of the client;

send the encrypted verification data to the client via a network page using a first network and a first communication protocol;

transmit a second verification code to the communication address using a second network and a second communication protocol; and

in response to receiving from the client via the first communication protocol the encrypted verification data and the transmitted second verification code received by the communication address, verify that the transmitted second verification code was received by the communication address by decrypting the received verification data, retrieving the sent first verification code from the decrypted verification data, and observing that the retrieved first verification code matches the second verification code received by the at least one computing device.

8. The system of claim 7, wherein the encrypted verification data is sent to the client via hypertext transfer protocol (HTTP), and the encrypted verification data and the second verification code are received from the client via an HTTP form submission.

9. The system of claim 7, wherein the client is unable to decrypt the encrypted verification data.

10. The system of claim 7, wherein the at least one computing device is configured not to persist the first verification code or the second verification code in data storage.

11. The system of claim 7, wherein the encrypted verification data further includes an identifier of the user account.

12

12. The system of claim 7, wherein when executed the at least one application further causes the at least one computing device to at least return an error to the client in response to determining that the retrieved first verification code does not match the second verification code.

13. A method for performing a stateless verification that a user of a client has access to a communication address, the method comprising:

generating, via at least one of one or more computing devices, encrypted verification data for a user account, the encrypted verification data including a first verification code and the communication address associated with the user of the client;

sending, using a first network and via at least one of the one or more computing devices, the encrypted verification data to the client via a first communication protocol;

transmitting, using a second network and via the at least one of the one or more computing devices, a second verification code to the communication address via a second communication protocol;

receiving from the client via the first communication protocol, by the one or more computing devices, the encrypted verification data and the transmitted second verification code received by the communication address; and

verifying, by the one or more computing devices, that the transmitted second verification code was received by the communication address by decrypting the received verification data, retrieving the sent first verification code from the decrypted verification data, and observing that the retrieved first verification code matches the second verification code received by the one or more computing devices.

14. The method of claim 13, further comprising generating, by the one or more computing devices, a network page including the encrypted verification data in a hidden form field.

15. The method of claim 13, further comprising authenticating, by the one or more computing devices, the client before sending the encrypted verification data to the client.

16. The method of claim 13, wherein generating the encrypted verification data further comprises encrypting, by the one or more computing devices, the encrypted verification data using a symmetric key.

17. The method of claim 13, wherein the encrypted verification data further includes an identifier of the user account, and the method further comprises identifying, by the one or more computing devices, the user account by retrieving the identifier of the user account from the decrypted verification data.

18. The method of claim 13, wherein the encrypted verification data further includes a timestamp, and the method further comprises determining, by the one or more computing devices, that the encrypted verification data is within a maximum threshold age by retrieving the timestamp from the decrypted verification data and comparing an age of the retrieved timestamp to the maximum threshold age.

19. The method of claim 13, wherein the encrypted verification data is sent to the client via hypertext transfer protocol (HTTP), and the encrypted verification data and the second verification code are received from the client via an HTTP form submission.

20. The method of claim 13, wherein the one or more computing devices are configured not to persist the first verification code or the second verification code in data storage.
