(57) **ABSTRACT**

Techniques are disclosed for forming transistor devices hav-
ing reduced parasitic contact resistance relative to conven-
tional devices. The techniques can be implemented, for
example, using a standard contact stack such as a series of
metals on, for example, silicon or silicon germanium (SiGe)
source/drain regions. In accordance with one example such
embodiment, an intermediate boron doped germanium layer
is provided between the source/drain and contact metals to
significantly reduce contact resistance. Numerous transistor
configurations and suitable fabrication processes will be
apparent in light of this disclosure, including both planar and
non-planar transistor structures (e.g., FinFETs), as well as
strained and unstrained channel structures. Graded buffering
can be used to reduce misfit dislocation. The techniques are
particularly well-suited for implementing p-type devices, but
can be used for n-type devices if so desired.

SELECTIVE GERMANIUM P-CONTACT METALIZATION THROUGH TRENCH

RELATED APPLICATION

This patent application is a continuation of U.S. application Ser. No. 13/990,238, filed May 29, 2013, and entitled "SELECTIVE GERMANIUM P-CONTACT METALIZATION THROUGH TRENCH," which is a U.S. National Phase application under 35 U.S.C. §371 of International Application No. PCT/US2011/054202, filed Sep. 30, 2011, and entitled, "SELECTIVE GERMANIUM P-CONTACT METALIZATION THROUGH TRENCH," which is a continuation-in-part of U.S. application Ser. No. 12/975,278, filed Dec. 21, 2010, and entitled "TRANSISTORS WITH HIGH CONCENTRATION OF BORON DOPED GERMANIUM," each of which are incorporated herein by reference in their entireties.

BACKGROUND

Increased performance of circuit devices including transistors, diodes, resistors, capacitors, and other passive and active electronic devices formed on a semiconductor substrate is typically a major factor considered during design, manufacture, and operation of those devices. For example, during design and manufacture or forming of, metal oxide semiconductor (MOS) transistor semiconductor devices, such as those used in a complementary metal oxide semiconductor (CMOS), it is often desired to minimize the parasitic resistance associated with contacts otherwise known as external resistance R_{ext} . Decreased R_{ext} enables higher current from an equal transistor design.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1A illustrates a MOS device configured with a boron doped germanium layer between the source/drain layer and contact metals, in accordance with an embodiment of the present invention.

FIG. 1B illustrates a MOS device configured with a boron doped germanium layer between the source/drain layer and contact metals, in accordance with another embodiment of the present invention.

FIG. 1C illustrates a MOS device configured with a boron doped germanium layer between the source/drain layer and contact metals, in accordance with another embodiment of the present invention.

FIG. 2 is a method for forming a transistor structure with low contact resistance in accordance with an embodiment of the present invention.

FIGS. 3A to 3I illustrate structures that are formed when carrying out the method of FIG. 2, in accordance with various embodiments of the present invention.

FIG. 4 is a method for forming a transistor structure with low contact resistance in accordance with another embodiment of the present invention.

FIGS. 5A to 5F illustrate structures that are formed when carrying out the method of FIG. 4, in accordance with various embodiments of the present invention.

FIG. 6 shows a perspective view of a FinFET transistor architecture, configured in accordance with one embodiment of the present invention.

FIG. 7 shows a plot of a split lot showing contact resistance for transistor structures configured with in accordance with embodiments of the present invention and standard transistor structures configured with no cap.

FIG. 8 illustrates a computing system implemented with one or more transistor structures in accordance with an example embodiment of the present invention.

As will be appreciated, the figures are not necessarily drawn to scale or intended to limit the claimed invention to the specific configurations shown. For instance, while some figures generally indicate straight lines, right angles, and smooth surfaces, an actual implementation of a transistor structure may have less than perfect straight lines, right angles, and some features may have surface topology or otherwise be non-smooth, given real world limitations of the processing equipment and techniques used. In short, the figures are provided merely to show example structures.

DETAILED DESCRIPTION

Techniques are disclosed for forming transistor devices having reduced parasitic contact resistance relative to conventional devices. The techniques can be implemented, for example, using a standard contact stack such as a series of metals on silicon or silicon germanium (SiGe) source/drain regions. In accordance with one example such embodiment, an intermediate boron doped germanium layer is provided between the source/drain and contact metals to significantly reduce contact resistance. Numerous transistor configurations and suitable fabrication processes will be apparent in light of this disclosure, including both planar and non-planar transistor structures (e.g., FinFETs), as well as strained and unstrained channel structures. The techniques are particularly well-suited for implementing p-type devices, but can be used for n-type devices if so desired.

General Overview

As previously explained, increased drive current in the transistors can be achieved by reducing device resistance. Contact resistance is one component of a device's overall resistance. A standard transistor contact stack typically includes, for example, a silicon or SiGe source/drain layer, a nickel silicide layer, a titanium nitride adhesion layer, and a tungsten contact/pad. In such configurations, the contact resistance is effectively limited by the silicon or SiGe valence band alignment to the pinning level in the metal. Typically, using industry standard silicides such as nickel (or other suitable silicides, such as titanium, cobalt, or platinum), this results in a band misalignment of about 0.5 eV. Thus, and in accordance with an example embodiment of the present invention, an intermediate boron doped germanium layer is provided between the source/drain and contact metals to significantly reduce the band misalignment value and contact resistance.

In one specific example embodiment, contacts configured with the intermediate boron doped germanium layer exhibit a reduction in the band misalignment value to less than 0.2 eV and a corresponding reduction in contact resistance of about 3× (relative to a conventional contact stack similarly configured, but without the intermediate boron doped germanium layer between the source/drain regions and contact metal). A transmission electron microscopy (TEM) cross section or secondary ion mass spectrometry (SIMS) profile can be used to show the germanium concentration throughout the vertical stack of the film structure, as profiles of epitaxial alloys of silicon and SiGe can readily be distinguished from germanium concentration profiles.

Thus, transistor structures configured in accordance with embodiments of the present invention provide an improvement over conventional structures with respect to lower contact resistance. Some such embodiments effectively marry superior contact properties of germanium with superior semi-

conductor transistor properties of Si and SiGe to provide next generation low resistance contacts. Selectivity can be achieved in various ways. In one embodiment, for instance, selectivity to n-type MOS (NMOS) source/drain locations can be provided by having NMOS regions masked off during p-type MOS device (PMOS) deposition. In another embodiment, both NMOS and PMOS regions can be open simultaneously, but deposition only occurs in the PMOS regions by way of a trench. An advantage here is that the low melting point germanium is absent during the relatively high thermal budget steps typical in the front end of a MOS flow. After trench processing and germanium deposition, and in accordance with one specific such example embodiment, the structure sees no temperatures above 500° C., and therefore the germanium overlayer is not in jeopardy of melting and or otherwise degrading performance. As will be further appreciated in light of this disclosure, selectively may include natural selectivity. For instance, while boron doped germanium grows on p-type SiGe (or silicon) source drain regions, it does not grow on dielectric surfaces such as silicon dioxide (SiO₂) or silicon nitride (SiN); nor does it grow on, for instance, exposed heavily phosphorous doped silicon in n-type regions.

Numerous transistor configurations and suitable fabrication processes will be apparent in light of this disclosure, including both planar and non-planar transistor structures (e.g., such as double-gate and trigate transistor structures), as well as strained and unstrained channel structures. Any number of such structural features and material systems can be used in conjunction with a germanium overlayer as described herein. The transistor structure may include p-type source/drain regions, n-type source/drain regions, or both n-type and p-type source/drain regions. In some example embodiments, the transistor structure includes dopant-implanted source/drain regions or epitaxial (or poly) replacement source/drain regions of silicon, SiGe alloys, or nominally pure germanium films (e.g., such as those with less than 10% silicon) in a MOS structure. In any such implementations, an overlayer or cap of boron doped germanium can be formed directly over the source/drain regions, in accordance with an embodiment of the present invention. A contact metal (or series of metals) can then be deposited and a subsequent reaction (annealing) can be carried out to form metal germanide source and drain contacts. As will be appreciated, the contact may be implemented as a stack including one or more of a silicide layer, an adhesion layer, and/or a metal pad layer. The boron doped germanium overlayer can be formed directly over other parts of the transistor structure as well, such as the poly gate and/or grounding tap regions, if so desired.

As is known, a MOS transistor may include source and drain tip regions that are designed to decrease the overall resistance of the transistor while improving short channel effects (SCE). Conventionally, these tip regions are portions of the substrate where a dopant such as boron or carbon is implanted using an implant and diffusion technique. The source tip region is formed in the area between the source region and the channel region. Likewise, the drain tip region is formed in the area between the drain region and the channel region. Some embodiments of the present invention are configured with such conventionally formed tip regions. In other example embodiments, fabrication techniques are employed to extend self-aligned epitaxial tip (SET) transistors to achieve very near to the theoretical limit of uniaxial strain. This can be accomplished, for instance, by selective epitaxial deposition in the source and drain regions as well as their corresponding tip regions to form a bilayer construction of boron doped silicon or SiGe (for the source/drain regions)

capped with an overlayer of a boron doped germanium layer in the source/drain and respective tip regions. The germanium and boron concentrations can vary, but in some example embodiments, the germanium concentration is in the range of 20 atomic % to 100 atomic %, and the boron concentration is in the range of 1E20 cm⁻³ to 2E21 cm⁻³ (e.g., germanium concentration in excess of 50 atomic % and boron concentration in excess of 2E20 cm⁻³). Note that the boron doped germanium layer may be provided in the tip regions, but in other embodiments is just provided over the source/drain regions (and not in the tip regions).

In still other example embodiments, an optional thin buffer with graded germanium concentration and/or boron concentration can be used as an interfacial layer between the underlying substrate with the source/drain layer (e.g., silicon or SiGe). Likewise, a thin buffer with graded germanium concentration and/or boron concentration can be used as an interfacial layer between the source/drain layer and the boron doped germanium cap. In still other embodiments, the boron doped germanium overlayer or source/drain layer themselves can have a graded germanium and/or boron concentration in a similar fashion as to the optional buffers. In any such case, since boron diffusion is suppressed in germanium (the higher the concentration, the greater the relative suppression), a high concentration of boron can be doped in the germanium, which in turn results in lower parasitic resistance and without degrading tip abruptness. In addition, the contact resistance is reduced from lowering of Schottky-barrier height.

Architecture and Methodology

FIG. 1A illustrates a MOS device **100A** formed on a substrate **102** and configured with a boron doped germanium layer between the source/drain layer and contact metals, in accordance with an embodiment of the present invention. In particular, boron doped germanium layer **117** is provided between the source layer **110** and contact metals **125**, and boron doped germanium layer **119** is provided between the drain layer **112** and contact metals **127**. The source region **110** and the drain region **112** can be formed using any number of conventional techniques. In this example embodiment, for instance, the source region **110** and the drain region **112** are formed by etching the substrate and then epitaxially depositing a silicon or silicon germanium material (e.g., with a germanium concentration in the range of, for instance, 10 to 70 atomic %).

A gate stack **122** is formed over a channel region **120** of the transistor **100A**. As can further be seen, the gate stack **122** includes a gate dielectric layer **106** and a gate electrode **104**, and spacers **108** are formed adjacent to the gate stack **122**. In some example cases, and depending on the technology node, the spacers **108** create a distance of about 10 to 20 nanometers (nm) between the edges of the gate dielectric layer **106** and the edges of each of the source and drain regions **110/112**. It is within this space that a source tip region **110A** and a drain tip region **112A** can be formed. In this example embodiment, the tip regions **110A/112A** are formed via a typical implantation-diffusion based process, and overlap the spacers **108** and may also overlap or underdiffuse the gate dielectric layer **106** by a distance of, for instance, less than 10 nm. In forming the implantation-diffusion based tip regions **110A/112A**, a dopant such as boron or carbon is implanted into the source region **110** and the drain region **112**. The transistor **100A** is then annealed to cause the dopant to diffuse towards the channel region **120**. Angled ion implantation techniques may also be used to further implant dopants into those areas between the gate dielectric layer **106** and the source/drain

regions **110/112**. Such implantation-diffusion-based tip formation processes generally do not induce a strain on the channel region.

In any case, and as will be appreciated in light of this disclosure, whether a transistor structure has a strained or unstrained channel, or source-drain tip regions or no source-drain tip regions, is not particularly relevant to various embodiments of the present invention, and such embodiments are not intended to be limited to any particular such structural features. Rather, any number of transistor structures and types can benefit from employing a boron doped germanium overlayer as described herein. The techniques provided herein are compatible, for instance, with conventional dopant implanted silicon, raised source/drain, strained SiGe (or other suitable materials), and any deposited epitaxial tip (sometimes referred to as source-drain extensions) that extend below the gate electrode dielectric or are spaced away from the vertical line defined by the gate electrode dielectric.

The germanium overlayer **117/119** is generally provided after formation of the source/drain regions **110/112** and prior to formation of the contacts **125/127**. The thickness of this overlayer **117/119** can vary from one embodiment to the next, but in one example embodiment is in the range of 50 to 250 Angstroms (Å). The boron concentration of overlayer **117/119** can also vary, but in one example embodiment is in the range of $1\text{E}20\text{ cm}^{-3}$ to $2\text{E}21\text{ cm}^{-3}$ (e.g., in excess of $2\text{E}20\text{ cm}^{-3}$). The overlayer **117/119** can be selectively deposited over the source/drain **110/112** regions (and/or other regions as desired, such as the poly gate or grounding tap regions). Any number of suitable deposition techniques can be used to provide the overlayer **117/119** (e.g., chemical vapor deposition, molecular beam epitaxy, etc). In accordance with one example embodiment, the contact metals **125** and **127** each comprise a stack a nickel silicide layer, a titanium nitride adhesion layer, and a tungsten contact/pad, and although any number of contact metal configurations can be used as will be appreciated in light of this disclosure. Standard deposition techniques can be used in providing the contact metals **125/127**.

FIG. 1B illustrates an example MOS device **100B** formed on a substrate **102** and configured with a boron doped germanium layer **117/119** between the source/drain layer **110/112** and contact metals **125/127**, in accordance with another embodiment of the present invention. This example configuration includes source and drain epitaxial tips (generally referred to herein as epi-tips). In more detail, the MOS transistor **100B** uses an undercut etch to allow the source region **110** and the drain region **112** to extend below the spacers **108**, and in some cases, below the gate dielectric layer **106**. The portions of the source/drain regions **110/112** that extend below the spacers **108** (and possibly the gate dielectric layer **106**) are generally referred to as the source epi-tip **110B** and the drain epi-tip **112B**, respectively. The source and drain epi-tips **110B/112B** replace the implantation/diffusion based tip regions **110A/112A** described with regard to FIG. 1A. In accordance with one embodiment, the source/drain regions **110/112** and the source/drain epi-tips **110B/112B** can be formed, for example, by etching the substrate **102**, which includes undercutting the spacers **108** (and possibly the gate dielectric layer **106**), and then using selective epitaxial deposition to provide, for instance, an in situ doped silicon, germanium, or SiGe to fill the source/drain regions **110/112** and the source/drain epi-tips **110B/112B**, as shown in FIG. 1B. Note the epitaxial fill may be raised relative to the surface of substrate **102**, as further shown in FIG. 1B, although non-raised configurations can be used as well. The germanium

overlayer **117/119** and the contact metals **125/127** can be implemented, for instance, as previously described with respect to FIG. 1A.

FIG. 1C illustrates a MOS device **100C** formed on a substrate **102** and configured with boron doped germanium layers **117/119** between the respective source/drain layers **110/112** and contact metals **125/127**, in accordance with another embodiment of the present invention. The source region **110** and the drain region **112** in this example embodiment are formed by implanting dopants such as boron into the substrate. The gate stack **122** is formed over a channel region **120** of the transistor **100C** and in this example case does not include sidewalls **108**. Nor does this example transistor structure include an undercut or tip regions like the embodiments shown in FIGS. 1A and 1B. The germanium overlayer **117/119** and the contact metals **125/127** can be implemented, for instance, as previously described with respect to FIG. 1A.

Numerous other variations and features can be implemented for transistor structures configured in accordance with an embodiment of the present invention. For example, a graded buffer may be used in one or more locations of the structure. For instance, the substrate **102** can be a silicon substrate, or a silicon film of a silicon on insulator (SOI) substrate, or a multi-layered substrate comprising silicon, silicon germanium, germanium, and/or III-V compound semiconductors. Thus, and by way of example, in an embodiment having a silicon or silicon germanium substrate **102** and an in situ boron doped SiGe fill in the source/drain regions **110/112** and the source/drain epi-tips **110B/112B**, a buffer can be provided between the underlying substrate **102** and the source/drain material. In one such embodiment, the buffer can be a graded boron doped (or intrinsic) silicon germanium layer with the germanium concentration graded from a base level compatible with the underlying substrate up to 100 atomic % (or near 100 atomic %, such as in excess of 90 atomic % or 95 atomic % or 98 atomic %). The boron concentration within this buffer can be either fixed (e.g., at a high level) or graded, for instance, from a base concentration at or otherwise compatible with the underlying substrate up to a desired high concentration (e.g., in excess of $2\text{E}20\text{ cm}^{-3}$). Note that ‘compatibility’ as used herein does not necessitate an overlap in concentration levels (for instance, the germanium concentration of underlying substrate can be 0 to 20 atomic % and initial germanium concentration of the buffer can be 30 to 40 atomic %). In addition, as used herein, the term ‘fixed’ with respect to a concentration level is intended to indicate a relatively constant concentration level (e.g., the lowest concentration level in the layer is within 10% of the highest concentration level within that layer). In a more general sense, a fixed concentration level is intended to indicate the lack of an intentionally graded concentration level. The thickness of the buffer can vary depending on factors such as the range of concentrations being buffered, but in some embodiments is in the range of 30 to 120 Å, such as 50 to 100 Å (e.g., 60 Å or 65 Å). As will be further appreciated in light of this disclosure, such a graded buffer beneficially lowers the Schottky-barrier height.

Alternatively, rather than using a thin buffer between the substrate **102** and the source/drain regions **110/112** and the source/drain epi-tips **110B/112B**, the source/drain material itself can be graded in a similar fashion. For example, and in accordance with one example embodiment, boron doped SiGe source/drain regions **110/112** and the source/drain epi-tips **110B/112B** can be configured with a germanium concentration graded from a base level concentration compatible with the underlying substrate (e.g., in the range of 30 to 70 atomic %) up to 100 atomic %. In some such embodiments,

the boron concentration within this boron doped germanium layer can range, for example, from a base concentration at or otherwise compatible with the underlying substrate up to a desired high concentration (e.g., in excess of $2E20\text{ cm}^{-3}$).

In other embodiments, a buffer can be provided between the source/drain material and the boron doped germanium overlayer **117/119**. In one such embodiment, the source/drain material is a boron doped SiGe layer having a fixed concentration of germanium (e.g., in the range of 30 to 70 atomic %) and the buffer can be a thin SiGe layer (e.g., 30 to 120 Å, such as 50 to 100 Å) having a germanium concentration graded from a base level concentration compatible with the underlying boron doped SiGe layer up to 100 atomic % (or near 100 atomic %, such as in excess of 90 atomic % or 95 atomic % or 98 atomic %). In some such cases, the boron concentration within this buffer can be fixed at a desired high level or can range, for example, from a base concentration at or otherwise compatible with the underlying SiGe layer up to the desired high concentration (e.g., in excess of $1E20\text{ cm}^{-3}$, $2E20\text{ cm}^{-3}$, or $3E20\text{ cm}^{-3}$). Alternatively, rather than using a buffer between the source/drain material and the boron doped germanium overlayer **117/119**, the overlayer **117/119** itself can be graded in a similar fashion. For example, and in accordance with one example embodiment, the boron doped overlayer **117/119** can be configured with a germanium concentration graded from a base level concentration compatible with the underlying substrate and/or source/drain regions (e.g., in the range of 30 to 70 atomic %) up to 100 atomic % (or near 100 atomic %). The boron concentration within this overlayer **117/119** layer can be fixed at a desired high level or can range, for example, from a base concentration at or otherwise compatible with the underlying substrate and/or source/drain regions up to the desired high level (e.g., in excess of $2E20\text{ cm}^{-3}$).

Thus, a low contact resistance architecture for numerous transistor devices is provided. The devices may be formed in part using any number of conventional processes such as, for example, by gate oxide, poly gate electrode, thin spacer, and an isotropic undercut etch in the source/drain regions (or an ammonia etch to form faceted fin recess in monocrystalline substrate, or other suitable etch to form fin recess). In accordance with some embodiments, selective epitaxial deposition can be used to provide in situ doped silicon or alternatively, a fully strained silicon germanium layer to form source/drain regions with or without tips. Optional buffers may be used as previously explained. Any suitable high-k replacement metal gate (RMG) process flow can also be used, where a high-k dielectric replaces the conventional gate oxide. Silicidation with, for example, nickel, nickel-platinum, or titanium with or without germanium pre-amorphization implants can be used to form a low resistance germanide. The techniques provided herein can be applied, for example, to benefit any technology nodes (e.g., 90 nm, 65 nm, 45 nm, 32 nm, 22 nm, 14 nm, and 10 nm transistors, and lower), and the claimed invention is not intended to be limited to any particular such nodes or range of device geometries. Other advantages will be apparent in light of this disclosure.

FIG. 2 is a method for forming a transistor structure with low contact resistance in accordance with an embodiment of the present invention. FIGS. 3A through 3I illustrate example structures that are formed as the method is carried out, and in accordance with some embodiments.

As can be seen, the method begins with forming **202** a gate stack on a semiconductor substrate upon which a MOS device, such as a PMOS transistor, may be formed. The semiconductor substrate may be implemented, for example, with a bulk silicon or a silicon-on-insulator configuration. In other

implementations, the semiconductor substrate may be formed using alternate materials, which may or may not be combined with silicon, such as germanium, silicon germanium, indium antimonide, lead telluride, indium arsenide, indium phosphide, gallium arsenide, or gallium antimonide. In a more general sense, any material that may serve as a foundation upon which a semiconductor device may be built can be used in accordance with embodiments of the present invention. The gate stack can be formed as conventionally done or using any suitable custom techniques. In some embodiments of the present invention, the gate stack may be formed by depositing and then patterning a gate dielectric layer and a gate electrode layer. For instance, in one example case, a gate dielectric layer may be blanket deposited onto the semiconductor substrate using conventional deposition processes such as chemical vapor deposition (CVD), atomic layer deposition (ALD), spin-on deposition (SOD), or physical vapor deposition (PVD). Alternate deposition techniques may be used as well, for instance, the gate dielectric layer may be thermally grown. The gate dielectric material may be formed, for example, from materials such as silicon dioxide or high-k dielectric materials. Examples of high-k gate dielectric materials include, for instance, hafnium oxide, hafnium silicon oxide, lanthanum oxide, lanthanum aluminum oxide, zirconium oxide, zirconium silicon oxide, tantalum oxide, titanium oxide, barium strontium titanium oxide, barium titanium oxide, strontium titanium oxide, yttrium oxide, aluminum oxide, lead scandium tantalum oxide, and lead zinc niobate. In some specific example embodiments, the high-k gate dielectric layer may be between around 5 Å to around 200 Å thick (e.g., 20 Å to 50 Å). In general, the thickness of the gate dielectric layer should be sufficient to electrically isolate the gate electrode from the neighboring source and drain contacts. In further embodiments, additional processing may be performed on the high-k gate dielectric layer, such as an annealing process to improve the quality of the high-k material. Next, a gate electrode material may be deposited on the gate dielectric layer using similar deposition techniques such as ALD, CVD, or PVD. In some such specific embodiments, the gate electrode material is polysilicon or a metal layer, although other suitable gate electrode materials can be used as well. The gate electrode material, which is may be a sacrificial material that is later removed for a replacement metal gate (RMG) process, has a thickness in the range of 50 Å to 500 Å (e.g., 100 Å), in some example embodiments. A conventional patterning process may then be carried out to etch away portions of the gate electrode layer and the gate dielectric layer to form the gate stack, as shown in FIG. 3A. As can be seen, FIG. 3A illustrates a substrate **300** upon which a gate stack is formed. In this example embodiment, the gate stack includes a gate dielectric layer **302** (which may be high-k gate dielectric material) and a sacrificial gate electrode **304**. In one specific example case, the gate stack includes a silicon dioxide gate dielectric layer **302** and a polysilicon gate electrode **304**. The gate stack may also include a gate hard mask layer **306** that provides certain benefits or uses during processing, such as protecting the gate electrode **304** from subsequent ion implantation processes. The hard mask layer **306** may be formed using typical hard mask materials, such as such as silicon dioxide, silicon nitride, and/or other conventional dielectric materials. FIG. 3A further illustrates spacers **310** formed on either side of the stack. The spacers **310** may be formed, for example, using conventional materials such as silicon oxide, silicon nitride, or other suitable spacer materials. The width of the spacers **310** may generally be chosen based on design requirements for the transistor being formed. In accordance with some

embodiments, however, the width of the spacers **310** is not subject to design constraints imposed by the formation of the source and drain epi-tips, given sufficiently high boron doped germanium content in the source/drain tip regions, as described herein (boron won't diffuse into channel).

With further reference to FIG. 2, after the gate stack is formed, the method continues with defining **204** the source/drain regions of the transistor structure. As previously explained, the source/drain regions can be implemented with any number of suitable processes and configurations. For example, the source/drain regions may be implanted, etched and epi filled, raised, silicon or SiGe alloy, p-type and/or n-type, and have a planar or fin shaped diffusion region. In the example embodiment shown in FIG. 3A, substrate **300** has been etched to provide cavities **312/314** as well as respective tip areas **312A/314A** which undercuts the gate dielectric **302**. FIG. 3B illustrates the substrate **300** after cavities **312/314** and tip areas **312A/314A** have been filled to provide the source/drain regions **318/320** and tip regions **318A/320A**. In accordance with some example embodiments, the source and drain region cavities **312/314** along with their respective tip areas **312A/314A** are filled with in situ doped silicon or SiGe, thereby forming source region **318** (along with epi-tip **318A**) and drain region **320** (along with drain epi-tip **320A**). Any number of source/drain layer configurations can be used here, with respect to materials (e.g., silicon, SiGe, III-V materials), dopant (e.g., boron in excess of $2E21\text{ cm}^{-3}$, or other suitable dopant/concentration), and dimension (e.g., thickness of source/drain layer may range, for instance, from 50 to 500 nm so as to provide a flush or raised source/drain region).

As previously explained, some such embodiments may include with a thin buffer between the source/drain layer and the substrate or the source/drain and boron doped germanium overlayer. For instance, and as can further be seen in the example embodiment shown in FIG. 3B, a source buffer **313** and a drain buffer **315** are deposited prior to depositing the source/drain materials. In some embodiments, the buffers **313** and **315** can be a graded boron doped silicon germanium layer with the germanium composition graded from a base level concentration compatible with the underlying substrate **300** material up to 100 atomic % (or near to 100 atomic % as previously described). The boron concentration can be appropriately graded as well. Numerous buffer schemes will be apparent in light of this disclosure.

With further reference to FIG. 2, after the source/drain regions are defined, the method continues with depositing **206** boron doped germanium on the source/drain regions of the transistor structure. FIG. 3C shows the boron doped germanium layer **317/319**. In some example embodiments, the boron doped germanium layer **317/319**, which may be epitaxially deposited in one or more layers, has a germanium concentration in excess of 90 atomic %, although other suitable concentration levels can be used as will be appreciated in light of this disclosure (e.g., in excess of 91 atomic %, or 92 atomic %, . . . , or 98 atomic %, or 99 atomic %, or truly pure germanium). As previously explained, this germanium concentration may be fixed or graded so as to increase from a base level (near substrate **300**) to a high level (e.g., in excess of 90 atomic %). The boron concentration in some such embodiments can be in excess of $1E20\text{ cm}^{-3}$, such as higher than $2E20\text{ cm}^{-3}$ or $2E21\text{ cm}^{-3}$, and may also be graded so as to increase from a base level near substrate **300** to a high level (e.g., in excess of $1E20\text{ cm}^{-3}$ or $2E20\text{ cm}^{-3}$ or $3E20\text{ cm}^{-3}$, . . . , $2E21\text{ cm}^{-3}$). In embodiments where the germanium concentration of the underlying source/drain regions **318/320** is fixed or otherwise relatively low, a graded buffer may be used to better interface source/drain regions **318/320**

with the boron doped germanium layer **317/319**, as previously explained. The thickness of the boron doped germanium cap **317/319** may have a thickness in the range, for example, of 50 to 250 Å, in accordance with some specific example embodiments, although alternative embodiments may have other layer thicknesses, as will be apparent in light of this disclosure.

In some embodiments, a CVD process or other suitable deposition technique may be used for the depositing **206** or otherwise forming the boron doped germanium layer **317/319**. For example, the depositing **206** may be carried out in a CVD, or rapid thermal CVD (RT-CVD), or low pressure CVD (LP-CVD), or ultra-high vacuum CVD (UHV-CVD), or gas source molecular beam epitaxy (GS-MBE) tool using germanium and boron containing precursors such as germane (GeH_4) or digermane (Ge_2H_6) and diborane (B_2H_6) or boron difluoride (BF_2). In some such embodiments, there may be a carrier gas such as, for instance, hydrogen, nitrogen, or a noble gas (e.g., precursor is diluted at 1-5% concentration of carrier gas). There may also be an etchant gas such as, for example, halogen-based gas such as hydrogen chloride (HCl), chlorine (Cl), or hydrogen bromide (HBr). The basic deposition of germanium and also boron doped germanium is possible over a wide range of conditions using deposition temperature in the range, for example, of 300° C. to 800° C. (e.g., $300\text{-}500^\circ\text{ C.}$) and reactor pressure, for instance, in the range 1 Torr to 760 Torr. Germanium is naturally selective in that it deposits on silicon or silicon-germanium alloy, and does not deposit on other materials such as silicon dioxide and silicon nitride. Since this natural selectivity is not entirely perfect, a small flow of etchant can be used to increase the selectivity of the deposition, as previously noted. Each of the carrier and etchants can have a flow in the range of 10 and 300 SCCM (typically, no more than 100 SCCM of flow is required, but some embodiments may require higher flow rates). In one specific example embodiment, the deposition **206** is carried out using GeH_4 that is diluted in hydrogen at a 1% concentration and at a flow rate that ranges between 100 and 1000 SCCM. For an in situ doping of boron, diluted B_2H_6 may be used (e.g., the B_2H_6 may be diluted in H_2 at 3% concentration and at a flow rate that ranges between 100 and 600 SCCM. In some such specific example cases, an etching agent of HCl or Cl_2 is added at a flow rate that ranges, for example, between 10 and 100 SCCM, to increase the selectivity of the deposition.

As will be appreciated in light of this disclosure, the selectivity at which the boron doped germanium layer **317/319** is deposited can vary as desired. In some cases, for instance, the boron doped germanium layer **317/319** is deposited only on the source/drain regions **318/320** or a portion of the source/drain regions **318/320** (rather than across the entire structure). Any number of masking/patterning techniques can be used to selectively deposit layer **317/319**. Moreover, other embodiments may benefit from layer **317/319** covering, for example, poly gate regions or grounding tap regions. As will further be appreciated in light of this disclosure, the combination of high germanium concentration (e.g., in excess of 90 atomic % and up to pure germanium) and high boron concentration (e.g., in excess of $2E20\text{ cm}^{-3}$) can be used to realize significantly lower contact resistance in the source and drain regions (and other areas where low contact resistance is desirable, such as ground tap regions), in accordance with some example embodiments. Further, and as previously explained, since boron diffusion is sufficiently suppressed by pure germanium, no adverse SCE degradation is realized with subsequent thermal anneals despite any high boron concentration proximate the channel (if applicable). Barrier height lowering

is also enabled from the higher concentration of germanium at the contact surface. In some example embodiments, a germanium concentration in excess of 95 atomic % and up to pure germanium (100 atomic %) can be used to achieve such benefits.

With further reference to FIG. 2, after the boron doped germanium layer 317/319 is provided, the method continues with depositing 208 a dielectric over layer 317/319. FIG. 3D shows dielectric 322 as being flush with the hard mask 306 of the gate stack, but it need not be. The dielectric can be configured in a number of ways. In some embodiments, dielectric 322 is implemented with SiO₂ or other low-k dielectric materials. In other embodiments, dielectric 322 is implemented with a SiN liner followed by one or more layers of SiO₂, or any combination of nitride, oxide, oxynitride, carbide, oxycarbide, or other suitable dielectric materials). The dielectric 322, which may be referred to as an interlayer dielectric (ILD), may be planarized as commonly done. Other example dielectric materials include, for instance, carbon doped oxide (CDO), organic polymers such as perfluorocyclobutane or polytetrafluoroethylene, fluorosilicate glass (FSG), and organosilicates such as silsesquioxane, siloxane, or organosilicate glass. In some example configurations, the ILD layer may include pores or other voids to further reduce its dielectric constant.

Next, in some embodiments of the present invention where a replacement metal gate (RMG) process is used and as best shown in FIG. 3E, the method may further include removing the gate stack (including the high-k gate dielectric layer 302, the sacrificial gate electrode 304, and the hard mask layer 306) using an etching process as conventionally done. In alternate implementations, only the sacrificial gate 304 and hard mask layer 306 are removed. FIG. 3E illustrates the trench opening that is formed when the gate stack is etched away, in accordance with one such embodiment. If the gate dielectric layer is removed, the method may continue with depositing a new gate dielectric layer into the trench opening (designated as 324 in FIG. 3F). Any suitable high-k dielectric materials such as those previously described may be used here, such as hafnium oxide. The same deposition processes may also be used. Replacement of the gate dielectric layer may be used, for example, to address any damage that may have occurred to the original gate dielectric layer during application of the dry and wet etch processes, and/or to replace a low-k or sacrificial dielectric material with a high-k or otherwise desired gate dielectric material. As further shown in FIG. 3F, the method may further continue with depositing the metal gate electrode layer 326 into the trench and over the gate dielectric layer 324. Conventional metal deposition processes may be used to form the metal gate electrode layer, such as CVD, ALD, PVD, electroless plating, or electroplating. The metal gate electrode layer may include, for example, a p-type workfunction metal, such as ruthenium, palladium, platinum, cobalt, nickel, and conductive metal oxides, e.g., ruthenium oxide. In some example configurations, two or more metal gate electrode layers may be deposited. For instance, a workfunction metal may be deposited in the gate trench followed by a suitable metal gate electrode fill metal such as aluminum or silver.

With further reference to FIG. 2, after dielectric layer 322 is provided over layer 317/319 (and any desired RMG process), the method continues with etching 210 to form the source/drain contact trenches. Any suitable dry and/or wet etch processes can be used. FIG. 3G shows the source/drain contact trenches after etching is complete, in accordance with one example embodiment. The method then continues with depositing 212 contact resistance reducing metal and anneal-

ing to form silicide/germanide, and then depositing 214 the source/drain contact plugs. FIG. 3H shows the contact metals 325/327, which in some embodiments includes the silicide/germanide, although other embodiments may include additional layers (e.g., adhesion layer). FIG. 3I shows the contact plug metal 329/331, which in some embodiments includes aluminum, although any suitably conductive contact metal or alloy can be used for the contact plug 329/331, such as silver, nickel-platinum or nickel-aluminum or other alloys of nickel and aluminum, or titanium, using conventional deposition processes. The germanide/metalization 212 of the source and drain contacts can be carried out, for instance, by silicidation with nickel, aluminum, nickel-platinum or nickel-aluminum or other alloys of nickel and aluminum, or titanium with or without germanium pre-amorphization implants to form a low resistance germanide. The boron doped germanium layer 317/319 allows for metal-germanide formation (e.g., nickel-germanium). The germanide allows for significantly lower Schottky-barrier height and improved contact resistance (including R_{ext}) over that in conventional metal-silicide systems. For instance, conventional transistors typically use a source/drain SiGe epi process, with germanium concentration in the range of 30-40 atomic %. Such conventional systems exhibit R_{ext} values of about 140 Ohm*um, limited by epi/silicide interfacial resistance, which is high and may impede future gate pitch scaling. Some embodiments of the present invention allow for a significant improvement in R_{ext} in PMOS devices (e.g., about a 2x improvement or better, such as a R_{ext} of about 70 Ohm*um), which can better support PMOS device scaling. Thus, transistors having a source/drain configured with boron doped germanium cap 317/319 in accordance with an embodiment of the present, with a boron concentration in excess of 1E20 cm⁻³ and a germanium concentration in excess of 90 atomic % and up to or otherwise near pure germanium (100 atomic %) at the interface between the source/drain regions 318/320 and the contact metals 325/327, can exhibit R_{ext} values of less than 100 Ohm*um, and in some cases less than 90 Ohm*um, and in some cases less than 80 Ohm*um, and in some cases less than 75 Ohm*um, or lower.

FIG. 4 is a method for forming a transistor structure with low contact resistance in accordance with another embodiment of the present invention. FIGS. 5A through 5F illustrate example structures that are formed as the method is carried out, and in accordance with some embodiments. As can be seen, this example transistor structure includes both p-type and n-type source and drain regions (designated p-S/D and n-S/D, respectively), and the boron doped germanium is selectively deposited on the p-type regions only. In general, this method is similar to the method described with reference to FIGS. 2 and 3A-H, except that the deposition of the boron doped germanium layer 317/319 on the source/drain regions is selectively carried out after the dielectric 322 is deposited and etched to form the contact trench.

The method includes forming 402 the gate stacks and defining 404 the various p-S/D and n-S/D regions using standard processing and as best shown in FIG. 5A. In some embodiments, the p-S/D and n-S/D regions can be doped to provide a desired degree of selectivity with respect to boron doped germanium. The method further includes depositing 406 the dielectric 322 directly over the p-S/D and n-S/D regions, as shown in FIG. 5B. The method continues with etching 408 to form the p-S/D and n-S/D region contact trenches, and then selectively depositing 410 the boron doped germanium layer 317/319 into the trench and onto the p-S/D regions (of which there may be one or more depending on the desired function and application of the transistor structure), as

best shown in FIGS. 5C and 5D. Depositing 410 can be carried out using any suitable deposition process, such as selective epitaxy. Once layer 317/319 is provided, the method continues with depositing 412 contact metals 325/327 on top of the layer 317/319 as well as on top of any exposed n-S/D regions, and then depositing 414 the source/drain contact plugs 329/331, as shown in FIGS. 5E and 5F. This alternate methodology provides the same benefit of improved contact resistance, but is more selective in where the boron doped germanium is deposited. Other such selective deposition processes will be apparent in light of this disclosure, using any suitable combination of masking/patterning and selective deposition techniques. As will be further appreciated, the previous relevant discussion with respect to similar parts of the method is equally applicable here.

FinFET Configuration

As is known, FinFET is a transistor built around a thin strip of semiconductor material (generally referred to as the fin). The transistor includes the standard field effect transistor (FET) nodes, including a gate, a gate dielectric, a source region, and a drain region. The conductive channel of the device resides on the outer sides of the fin beneath the gate dielectric. Specifically, current runs along both sidewalls of the fin (sides perpendicular to the substrate surface) as well as along the top of the fin (side parallel to the substrate surface). Because the conductive channel of such configurations essentially resides along the three different outer, planar regions of the fin, such a FinFET design is sometimes referred to as a tri-gate FinFET. Other types of FinFET configurations are also available, such as so-called double-gate FinFETs, in which the conductive channel principally resides only along the two sidewalls of the fin (and not along the top of the fin).

FIG. 6 shows a perspective view of an example tri-gate architecture, configured in accordance with one embodiment of the present invention. As can be seen, the tri-gate device includes a substrate 600 having a semiconductor body or fin 660 (represented by dashed lines) extending from the substrate 600 through isolation regions 610, 620. A gate electrode 640 is formed over 3 surfaces of the fin 660 to form 3 gates. A hard mask 690 is formed on top of the gate electrode 640. Gate spacers 670, 680 are formed at opposite sidewalls of the gate electrode 640.

A source region comprises the epitaxial region 631 formed on a recessed source interface 650 and on one fin 660 sidewall, and a drain region comprises the epitaxial region 631 formed on a recessed source interface 650 and on the opposing fin 660 sidewall (not shown). A cap layer 641 is deposited over the epitaxial regions 631. Note that the boron cap layer 641 may be provided in the recessed (tip) regions, but in other embodiments is just provided over the source/drain regions (and not in the recessed regions). In one embodiment, the isolation regions 610, 620 are shallow trench isolation (STI) regions formed using conventional techniques, such as etching the substrate 600 to form trenches, and then depositing oxide material onto the trenches to form the STI regions. The isolation regions 610, 620 can be made from any suitable dielectric/insulative material, such as SiO₂. The previous discussion with respect to the substrate 102 is equally applicable here (e.g., substrate 600 may be a silicon substrate, or SOI substrate, or a multi-layered substrate).

As will be appreciated in light of this disclosure, conventional processes and forming techniques can be used to fabricate the FinFET transistor structure. However, and in accordance with one example embodiment of the present invention, the bilayer structure of the epitaxial region 631 and cap layer 641 can be implemented, for instance, using an in situ doped silicon or SiGe (for 631) capped with a boron

doped germanium (for 641), with an optional germanium and/or boron graded buffer between the two bilayers. As previously explained, such a buffer may be used to transition from a base level germanium/boron concentration compatible with the epitaxial region 631 to the boron doped germanium cap 641. Alternatively, germanium and/or boron concentration grading can be implemented directly in the epitaxial region 631 and/or the cap 641, rather than in an intervening graded buffer arrangement. As will further be appreciated, note that an alternative to the tri-gate configuration is a double-gate architecture, which includes a dielectric/isolation layer on top of the fin 660.

FIG. 7 shows a plot of a split lot showing contact resistance for transistor structures configured with in accordance with embodiments of the present invention and standard transistor structures configured with no cap. The transistor structures associated with the high resistance numbers in excess of 0.18 are all implemented with standard SiGe alloy raised PMOS source/drain regions with contact metal deposited directly thereon. The transistor structures associated with the resistance numbers of 0.107 and lower are all similarly implemented but with the addition a boron doped germanium cap between the source/drain regions and contact metal, in accordance with various embodiments of the present invention. Table 1 shows the raw data quantiles resulting from testing of the example structures with and without a boron doped germanium cap as described herein.

TABLE 1

Ge Cap	Min	10%	25%	Median	75%	90%	Max
Yes	0.032	0.032	0.033	0.040	0.078	0.105	0.107
No	0.183	0.183	0.192	0.239	0.250	0.265	0.265

As can be seen, this example lot actually shows an improvement (reduction) in contact resistance of about a three to six times (3× to 6×) over conventional transistor structures. The units are Ohms per arbitrary area.

Other improvements enabled by using a boron doped germanium cap in accordance with an embodiment of the present invention will be apparent in light of this disclosure. In particular, the resulting germanide materials and Schottky barrier height improvement enables more than a $2 \times R_{ext}$ improvement over that in conventional SiGe source/drain PMOS devices, in accordance with some example embodiments of the present invention. As is known, the Schottky barrier height is the barrier for electrical conduction across a semiconductor-metal junction. The magnitude of the Schottky barrier height reflects a mismatch in the energy position of the metal's Fermi level and the majority carrier band edge of the semiconductor across the semiconductor-metal interface. For a p-type semiconductor-metal interface, the Schottky barrier height is the difference between the metal Fermi level and the valence band maximum of the semiconductor.

Example System

FIG. 8 illustrates a computing device 1000 configured in accordance with one embodiment of the invention. As can be seen, the computing device 1000 houses a motherboard 1002. The motherboard 1002 may include a number of components, including but not limited to a processor 1004 and at least one communication chip 1006, each of which can be physically and electrically coupled to the motherboard 1002, or otherwise integrated therein. As will be appreciated, the motherboard 1002 may be, for example, any printed circuit board, whether a main board or a daughterboard mounted on a main board or the only board of device 1000, etc. Depending on its

applications, computing device **1000** may include one or more other components that may or may not be physically and electrically coupled to the motherboard **1002**. These other components may include, but are not limited to, volatile memory (e.g., DRAM), non-volatile memory (e.g., ROM), a graphics processor, a digital signal processor, a crypto processor, a chipset, an antenna, a display, a touchscreen display, a touchscreen controller, a battery, an audio codec, a video codec, a power amplifier, a global positioning system (GPS) device, a compass, an accelerometer, a gyroscope, a speaker, a camera, and a mass storage device (such as hard disk drive, compact disk (CD), digital versatile disk (DVD), and so forth). Any of the components included in computing device **1000** may include one or more transistor structures as described herein. In some embodiments, multiple functions can be integrated into one or more chips (e.g., for instance, note that the communication chip **1006** can be part of or otherwise integrated into the processor **1004**).

The communication chip **1006** enables wireless communications for the transfer of data to and from the computing device **1000**. The term “wireless” and its derivatives may be used to describe circuits, devices, systems, methods, techniques, communications channels, etc., that may communicate data through the use of modulated electromagnetic radiation through a non-solid medium. The term does not imply that the associated devices do not contain any wires, although in some embodiments they might not. The communication chip **1006** may implement any of a number of wireless standards or protocols, including but not limited to Wi-Fi (IEEE 802.11 family), WiMAX (IEEE 802.16 family), IEEE 802.20, long term evolution (LTE), Ev-DO, HSPA+, HSDPA+, HSUPA+, EDGE, GSM, GPRS, CDMA, TDMA, DECT, Bluetooth, derivatives thereof, as well as any other wireless protocols that are designated as 3G, 4G, 5G, and beyond. The computing device **1000** may include a plurality of communication chips **1006**. For instance, a first communication chip **1006** may be dedicated to shorter range wireless communications such as Wi-Fi and Bluetooth and a second communication chip **1006** may be dedicated to longer range wireless communications such as GPS, EDGE, GPRS, CDMA, WiMAX, LTE, Ev-DO, and others.

The processor **1004** of the computing device **1000** includes an integrated circuit die packaged within the processor **1004**. In some embodiments of the present invention, the integrated circuit die of the processor includes an onboard non-volatile memory or cache, and/or is otherwise communicatively coupled to off-chip memory that is implemented with one or more transistor structures as described herein. The term “processor” may refer to any device or portion of a device that processes, for instance, electronic data from registers and/or memory to transform that electronic data into other electronic data that may be stored in registers and/or memory.

The communication chip **1006** may also include an integrated circuit die packaged within the communication chip **1006**. In accordance with some such example embodiments, the integrated circuit die of the communication chip includes one or more devices implemented with one or more transistor structures as described herein. As will be appreciated in light of this disclosure, note that multi-standard wireless capability may be integrated directly into the processor **1004** (e.g., where functionality of any chips **1006** is integrated into processor **1004**, rather than having separate communication chips). Further note that processor **1004** may be a chip set having such wireless capability. In short, any number of processor **1004** and/or communication chips **1006** can be used. Likewise, any one chip or chip set can have multiple functions integrated therein.

In various implementations, the computing device **1000** may be a laptop, a netbook, a notebook, a smartphone, a tablet, a personal digital assistant (PDA), an ultra-mobile PC, a mobile phone, a desktop computer, a server, a printer, a scanner, a monitor, a set-top box, an entertainment control unit, a digital camera, a portable music player, or a digital video recorder. In further implementations, the device **1000** may be any other electronic device that processes data or employs transistors.

Numerous embodiments will be apparent in light of this disclosure, and features described herein can be combined in any number of configurations. One example embodiment of the present invention provides a transistor device. The device includes a substrate having a channel region, and a gate electrode above the channel region. A gate dielectric layer is provided between the gate electrode and the channel region, and p-type and n-type source/drain regions are provided in the substrate and adjacent to the channel region. The device further includes a boron doped germanium layer on at least a portion of the p-type source/drain region. This boron doped germanium layer comprises a germanium concentration in excess of 90 atomic % and a boron concentration in excess of $1E20\text{ cm}^{-3}$. The device further includes a metal-germanide source/drain contact on the boron doped germanium layer. In one such example, the boron doped germanium layer is only on p-type source/drain regions of the device. In another example case, the device further includes an interlayer dielectric. In another example case, the device further includes a graded buffer between the substrate and at least one of the p-type and n-type source/drain regions, and/or a graded buffer between at least one of the p-type and n-type source/drain regions and the boron doped germanium layer. In one such case, the graded buffer between the at least one p-type and n-type source and drain regions and the boron doped germanium layer has a germanium concentration that is graded from a base level concentration compatible with the at least one of the p-type and n-type source/drain regions to a high concentration in excess of 95 atomic %. In one such specific example case, the high concentration reflects pure germanium. In another example case, the graded buffer between the at least one of the p-type and n-type source/drain regions and the boron doped germanium layer has a boron concentration that is graded from a base level concentration compatible with the at least one of the p-type and n-type source/drain regions to a high concentration in excess of $1E20\text{ cm}^{-3}$. In another example case, the boron doped germanium layer has a graded concentration of at least one of germanium and boron. In another example case, the p-type and n-type source/drain regions comprise silicon germanium having a germanium concentration that is graded from a base level concentration compatible with the substrate to a high concentration in excess of 50 atomic %, and the boron doped germanium layer has a germanium concentration in excess of 95 atomic %. In another example case, the p-type and n-type source/drain regions comprise boron doped silicon germanium having a boron concentration that is graded from a base level concentration compatible with the substrate to a high concentration in excess of $1E20\text{ cm}^{-3}$. In another example case, the p-type and n-type source/drain regions comprise silicon or silicon germanium, and the device further comprises a buffer between at least one of the p-type and n-type source/drain regions and the boron doped germanium layer, the buffer having a germanium concentration that is graded from a base level concentration compatible with the at least one of the p-type and n-type source/drain regions to a high concentration in excess of 50 atomic %, and a boron concentration that is graded from a base level concentration compatible with the

at least one of the p-type and n-type source/drain regions to a high concentration in excess of $1E20 \text{ cm}^{-3}$. In another example case, the boron doped germanium layer comprises a germanium concentration in excess of 98 atomic %, and a boron concentration in excess of $2E20 \text{ cm}^{-3}$. Another embodiment provides an electronic device that includes a printed circuit board having one or more integrated circuits, wherein at least one of the one or more integrated circuits comprises one or more transistor devices as variously defined in this paragraph. In one such case, the one or more integrated circuits includes at least one of a communication chip and/or a processor, and at least one of the communication chip and/or processor comprises the one or more transistor devices. In another such case, the device is a computing device (e.g., mobile telephone or smartphone, laptop, tablet computer, etc).

Another embodiment of the present invention provides a transistor device. In this example case, the device includes a substrate having a channel region, and a gate electrode above the channel region, wherein a gate dielectric layer is provided between the gate electrode and the channel region and spacers are provided on sides of the gate electrode. The device further includes p-type and n-type source/drain regions in the substrate and adjacent to the channel region, each of the p-type and n-type source/drain regions including a tip region that extends under the gate dielectric layer and/or a corresponding one of the spacers. The device further includes a boron doped germanium layer on at least a portion of the p-type source/drain region, and comprising a germanium concentration in excess of 95 atomic % and a boron concentration in excess of $2E20 \text{ cm}^{-3}$. The device further includes metal-germanide source/drain contacts on the boron doped germanium layer. The device is one of a planar or FinFET transistor. In one such example case, the device further includes a buffer between at least one of the p-type and n-type source/drain regions and the boron doped germanium layer, wherein the buffer has a germanium concentration that is graded from a base level concentration compatible with the at least one of the p-type and n-type source/drain regions to a high concentration in excess of 95 atomic %, and a boron concentration that is graded from a base level concentration compatible with the at least one of the p-type and n-type source/drain regions to a high concentration in excess of $2E20 \text{ cm}^{-3}$. In another example case, the boron doped germanium layer has a graded concentration of at least one of germanium and boron. In another example case, the p-type and n-type source/drain regions comprise silicon germanium having a germanium concentration that is graded from a base level concentration compatible with the substrate to a high concentration in excess of 50 atomic %, and the boron doped germanium layer has a germanium concentration in excess of 98 atomic %. In another example case, the p-type and n-type source/drain regions have a boron concentration that is graded from a base level concentration compatible with the substrate to a high concentration in excess of $2E20 \text{ cm}^{-3}$. In another example case, the p-type and n-type source/drain regions comprise silicon germanium having a fixed germanium concentration, and the device further comprises a buffer between the p-type and n-type source/drain regions and the boron doped germanium layer, the buffer having a germanium concentration that is graded from a base level concentration compatible with the p-type and n-type source/drain regions to a high concentration in excess of 50 atomic %, and a boron concentration that is graded from a base level concentration compatible with the p-type and n-type source/drain regions to a high concentration in excess of $2E20 \text{ cm}^{-3}$, the buffer having a thickness of less than 100 Angstroms. Another embodiment provides a computing

device (e.g., desktop or portable computer, etc) that includes a printed circuit board having a communication chip and/or a processor, wherein at least one of the communication chip and/or processor comprises one or more transistor devices as variously defined in this paragraph.

Another embodiment of the present invention provides a method for forming a transistor device. The method includes providing a substrate having a channel region, and providing a gate electrode above the channel region, wherein a gate dielectric layer is provided between the gate electrode and the channel region. The method continues with providing p-type and n-type source/drain regions in the substrate and adjacent to the channel region, and providing a boron doped germanium layer on at least a portion of the p-type source/drain region. The boron doped germanium layer comprises a germanium concentration in excess of 90 atomic % and a boron concentration in excess of $1E20 \text{ cm}^{-3}$. The method continues with providing metal-germanide source/drain contacts on the boron doped germanium layer. In some example such cases, the method further includes providing a graded buffer between the substrate and at least one of the p-type and n-type source/drain regions, and/or providing a graded buffer between at least one of the p-type and n-type source/drain regions and the boron doped germanium layer. In another example case, the boron doped germanium layer has a graded concentration of at least one of germanium and boron (which may be used with or without graded buffers). This method may be employed, for example, in the fabrication of any electronic devices such as a computing device.

The following examples pertain to further embodiments, from which numerous permutations and configurations will be apparent.

Example 1 is a transistor device, comprising: a substrate having a channel region; a gate electrode above the channel region, wherein a gate dielectric layer is provided between the gate electrode and the channel region; p-type and n-type source/drain regions in the substrate and adjacent to the channel region; a boron doped germanium layer on at least a portion of the p-type source/drain region, and comprising a germanium concentration in excess of 90 atomic % and a boron concentration in excess of $1E20 \text{ cm}^{-3}$; and a metal-germanide source/drain contact on the boron doped germanium layer.

Example 2 includes the subject matter of Example 1, wherein the device is one of a planar or FinFET transistor.

Example 3 includes the subject matter of any of Examples 1-2, wherein the boron doped germanium layer is only on p-type source/drain regions of the device.

Example 4 includes the subject matter of any of Examples 1-3, further comprising an interlayer dielectric.

Example 5 includes the subject matter of any of Examples 1-4, further comprising at least one of: a graded buffer between the substrate and at least one of the p-type and n-type source/drain regions; and a graded buffer between at least one of the p-type and n-type source/drain regions and the boron doped germanium layer.

Example 6 includes the subject matter of Example 5, wherein the graded buffer between at least one of the p-type and n-type source/drain regions and the boron doped germanium layer has a germanium concentration that is graded from a base level concentration compatible with the at least one of the p-type and n-type source/drain regions to a high concentration in excess of 95 atomic %.

Example 7 includes the subject matter of Example 6, wherein the high concentration reflects pure germanium.

Example 8 includes the subject matter of any of Examples 5-7, wherein the graded buffer between the at least one of the

p-type and n-type source/drain regions and the boron doped germanium layer has a boron concentration that is graded from a base level concentration compatible with the at least one of the p-type and n-type source/drain regions to a high concentration in excess of $1E20\text{ cm}^{-3}$.

Example 9 includes the subject matter of any of Examples 1-8, wherein the boron doped germanium layer has a graded concentration of at least one of germanium and boron.

Example 10 includes the subject matter of any of Examples 1-9, wherein the p-type and n-type source/drain regions comprise silicon germanium having a germanium concentration that is graded from a base level concentration compatible with the substrate to a high concentration in excess of 50 atomic %, and the boron doped germanium layer has a germanium concentration in excess of 95 atomic %.

Example 11 includes the subject matter of any of Examples 1-10, wherein the p-type and n-type source/drain regions comprise boron doped silicon germanium having a boron concentration that is graded from a base level concentration compatible with the substrate to a high concentration in excess of $1E20\text{ cm}^{-3}$.

Example 12 includes the subject matter of any of Examples 1-4, wherein the p-type and n-type source/drain regions comprise silicon or silicon germanium, and the device further comprises a buffer between at least one of the p-type and n-type source/drain regions and the boron doped germanium layer, the buffer having a germanium concentration that is graded from a base level concentration compatible with the at least one p-type and n-type source/drain regions to a high concentration in excess of 50 atomic %, and a boron concentration that is graded from a base level concentration compatible with the at least one of the p-type and n-type source/drain regions to a high concentration in excess of $1E20\text{ cm}^{-3}$.

Example 13 includes the subject matter of any of Examples 1-12, wherein the boron doped germanium layer comprises a germanium concentration in excess of 98 atomic %, and a boron concentration in excess of $2E20\text{ cm}^{-3}$.

Example 14 is an electronic device comprising: a printed circuit board having one or more integrated circuits, wherein at least one of the one or more integrated circuits comprises one or more transistor devices as defined in any of the preceding claims.

Example 15 includes the subject matter of Example 14, wherein the one or more integrated circuits includes at least one of a communication chip and/or a processor, and at least one of the communication chip and/or processor comprises the one or more transistor devices.

Example 16 includes the subject matter of Examples 14-15, wherein the device is a computing device.

Example 17 is a transistor device, comprising: a substrate having a channel region; a gate electrode above the channel region, wherein a gate dielectric layer is provided between the gate electrode and the channel region and spacers are provided on sides of the gate electrode; p-type and n-type source/drain regions in the substrate and adjacent to the channel region, each of the p-type and n-type source/drain regions including a tip region that extends under the gate dielectric layer and/or a corresponding one of the spacers; a boron doped germanium layer on at least a portion of the p-type source/drain region, and comprising a germanium concentration in excess of 95 atomic % and a boron concentration in excess of $2E20\text{ cm}^{-3}$; and a metal-germanide source/drain contact on the boron doped germanium layer; wherein the device is one of a planar or FinFET transistor.

Example 18 includes the subject matter of Example 17, further comprising: a buffer between at least one of the p-type and n-type source/drain regions and the boron doped germa-

nium layer, wherein the buffer has a germanium concentration that is graded from a base level concentration compatible with the at least one of the p-type and n-type source/drain regions to a high concentration in excess of 95 atomic %, and a boron concentration that is graded from a base level concentration compatible with the at least one of the p-type and n-type source/drain regions to a high concentration in excess of $2E20\text{ cm}^{-3}$.

Example 19 includes the subject matter of Example 17, wherein the boron doped germanium layer has a graded concentration of at least one of germanium and boron.

Example 20 includes the subject matter of Example 17, wherein the p-type and n-type source/drain regions comprise silicon germanium having a germanium concentration that is graded from a base level concentration compatible with the substrate to a high concentration in excess of 50 atomic %, and the boron doped germanium layer has a germanium concentration in excess of 98 atomic %.

Example 21 includes the subject matter of Example 20, wherein the p-type and n-type source/drain regions have a boron concentration that is graded from a base level concentration compatible with the substrate to a high concentration in excess of $2E20\text{ cm}^{-3}$.

Example 22 includes the subject matter of Example 17, wherein the p-type and n-type source/drain regions comprise silicon germanium having a fixed germanium concentration, and the device further comprises a buffer between the p-type and n-type source/drain regions and the boron doped germanium layer, the buffer having a germanium concentration that is graded from a base level concentration compatible with the p-type and n-type source/drain regions to a high concentration in excess of 50 atomic %, and a boron concentration that is graded from a base level concentration compatible with the p-type and n-type source/drain regions to a high concentration in excess of $2E20\text{ cm}^{-3}$, the buffer having a thickness of less than 100 Angstroms.

Example 23 is a method for forming a transistor device, comprising: providing a substrate having a channel region; providing a gate electrode above the channel region, wherein a gate dielectric layer is provided between the gate electrode and the channel region; and providing p-type and n-type source/drain regions in the substrate and adjacent to the channel region; providing a boron doped germanium layer on at least a portion of the p-type source/drain region, the boron doped germanium layer comprising a germanium concentration in excess of 90 atomic % and a boron concentration in excess of $1E20\text{ cm}^{-3}$; and providing metal-germanide source/drain contacts on the boron doped germanium layer.

The foregoing description of example embodiments of the invention has been presented for the purposes of illustration and description. It is not intended to be exhaustive or to limit the invention to the precise forms disclosed. Many modifications and variations are possible in light of this disclosure. It is intended that the scope of the invention be limited not by this detailed description, but rather by the claims appended hereto.

What is claimed is:

1. A semiconductor device, comprising:

- a substrate;
- p-type source and drain regions in the substrate and adjacent to a corresponding channel region in the substrate;
- n-type source and drain regions in the substrate and adjacent to a corresponding channel region in the substrate;
- a gate electrode above each channel region, wherein a gate dielectric layer is provided between the gate electrode and the channel region;

21

an insulation layer over the substrate, the insulation layer having a contact trench formed over at least each of the p-type source and drain regions;
 a boron doped germanium layer entirely within the contact trenches and on at least a portion of the corresponding p-type source and drain regions, the boron doped germanium layer comprising a germanium concentration in excess of 50 atomic % and a boron concentration in excess of $2E20\text{ cm}^{-3}$; and
 a metal source/drain contact at least partially within each of the contact trenches and on the boron doped germanium layer.

2. The device of claim 1 wherein the device comprises FinFET transistor architecture, such that each channel region is associated with a semiconductor body that extends from the substrate through the insulation layer, and the corresponding gate electrode is formed over three surfaces of the semiconductor body to form three gates.

3. The device of claim 1 wherein the boron doped germanium layer is only on p-type source/drain regions of the device, and the contacts associated therewith each comprise a metal-germanide.

4. The device of claim 1 wherein the insulation layer comprises silicon dioxide.

5. The device of claim 1, further comprising at least one of:
 a graded buffer between the substrate and at least one of the p-type and n-type source/drain regions; and
 a graded buffer between at least one of the p-type and n-type source/drain regions and the boron doped germanium layer.

6. The device of claim 5 wherein the graded buffer between at least one of the p-type and n-type source/drain regions and the boron doped germanium layer has a germanium concentration that is graded from a base level concentration compatible with the at least one of the p-type and n-type source/drain regions to a high concentration in excess of 95 atomic %.

7. The device of claim 6 wherein the high concentration reflects pure germanium.

8. The device of claim 5 wherein the graded buffer between the at least one of the p-type and n-type source/drain regions and the boron doped germanium layer has a boron concentration that is graded from a base level concentration compatible with the at least one of the p-type and n-type source/drain regions to a high concentration in excess of $1E20\text{ cm}^{-3}$.

9. The device of claim 1 wherein the boron doped germanium layer has a graded concentration of at least one of germanium and boron.

10. The device of claim 1 wherein the p-type and n-type source/drain regions comprise silicon germanium having a germanium concentration that is graded from a base level concentration compatible with the substrate to a high concentration in excess of 50 atomic %, and the boron doped germanium layer has a germanium concentration in excess of 95 atomic %.

11. The device of claim 1 wherein the p-type and n-type source/drain regions comprise boron doped silicon germanium having a boron concentration that is graded from a base level concentration compatible with the substrate to a high concentration in excess of $1E20\text{ cm}^{-3}$.

12. The device of any of claim 1 wherein the p-type and n-type source/drain regions comprise silicon or silicon germanium, and the device further comprises a buffer between at least one of the p-type and n-type source/drain regions and the boron doped germanium layer, the buffer having a germanium concentration that is graded from a base level concentration compatible with the at least one p-type and n-type source/drain regions to a high concentration in excess of 50

22

atomic %, and a boron concentration that is graded from a base level concentration compatible with the at least one of the p-type and n-type source/drain regions to a high concentration in excess of $1E20\text{ cm}^{-3}$.

13. The device of claim 1 wherein the boron doped germanium layer comprises a germanium concentration in excess of 98 atomic %, and a boron concentration in excess of $2E20\text{ cm}^{-3}$.

14. A semiconductor device, comprising:

a substrate having a plurality of fins extending from the substrate, each fin including a channel region;
 a gate electrode around each channel region so as to provide a tri-gate structure, wherein a gate dielectric layer is provided between the gate electrode and the channel region and spacers are provided on sides of the gate electrode;

p-type source and drain regions in the substrate and adjacent to a corresponding channel region;

n-type source and drain regions in the substrate and adjacent to a corresponding channel region;

an insulation layer over the substrate, the insulation layer having a contact trench formed over at least each of the p-type source and drain regions;

a boron doped germanium layer entirely within the contact trenches and on at least a portion of the corresponding p-type source and drain regions, the boron doped germanium layer comprising a germanium concentration in excess of 50 atomic % and a boron concentration in excess of $2E20\text{ cm}^{-3}$; and

a metal source/drain contact at least partially within each of the contact trenches.

15. The device of claim 14, the device further comprising:
 a buffer between at least one of the p-type and n-type source/drain regions and the boron doped germanium layer, wherein the buffer has a germanium concentration that is graded from a base level concentration compatible with the at least one of the p-type and n-type source/drain regions to a high concentration in excess of 95 atomic %, and a boron concentration that is graded from a base level concentration compatible with the at least one of the p-type and n-type source/drain regions to a high concentration in excess of $2E20\text{ cm}^{-3}$.

16. The device of claim 14 wherein the boron doped germanium layer has a graded concentration of at least one of germanium and boron.

17. The device of claim 14 wherein the p-type and n-type source/drain regions comprise silicon germanium having a germanium concentration that is graded from a base level concentration compatible with the substrate to a high concentration in excess of 50 atomic %, and the boron doped germanium layer has a germanium concentration in excess of 98 atomic %.

18. The device of claim 17 wherein the p-type and n-type source/drain regions have a boron concentration that is graded from a base level concentration compatible with the substrate to a high concentration in excess of $2E20\text{ cm}^{-3}$.

19. The device of claim 14 wherein the p-type and n-type source/drain regions comprise silicon germanium having a fixed germanium concentration, and the device further comprises a buffer between the p-type and n-type source/drain regions and the boron doped germanium layer, the buffer having a germanium concentration that is graded from a base level concentration compatible with the p-type and n-type source/drain regions to a high concentration in excess of 50 atomic %, and a boron concentration that is graded from a base level concentration compatible with the p-type and

n-type source/drain regions to a high concentration in excess of $2E20 \text{ cm}^{-3}$, the buffer having a thickness of less than 100 Angstroms.

20. A method for forming a transistor device, comprising:
- providing a substrate; 5
 - providing p-type source and drain regions in the substrate and adjacent to a corresponding channel region in the substrate;
 - providing n-type source and drain regions in the substrate and adjacent to a corresponding channel region in the 10 substrate;
 - providing a gate electrode above the channel region, wherein a gate dielectric layer is provided between the gate electrode and the channel region; and
 - providing an insulation layer over the substrate; 15
 - forming a contact trench in the insulation layer over at least each of the p-type source and drain regions;
 - providing a boron doped germanium layer entirely within the contact trenches and on at least a portion of the 20 corresponding p-type source and drain regions, the boron doped germanium layer comprising a germanium concentration in excess of 50 atomic % and a boron concentration in excess of $2E20 \text{ cm}^{-3}$; and
 - providing metal-germanide source/drain contacts on the boron doped germanium layer. 25
