(57) **ABSTRACT**

Provisioning, managing and tracking of services provided by
a cloud infrastructure system are described. A subscription
order request from a customer for services provided by the
cloud infrastructure system is received. A workflow is defined
that includes steps to process the subscription order. The
workflow enables a customer to gain access to services
requested in a subscription order upon placing the subscrip-
tion order without the customer having to wait until all the
steps involved in processing the subscription order are com-
plete.

WORKFLOWS FOR PROCESSING CLOUD SERVICES**CROSS-REFERENCES TO RELATED APPLICATIONS**

The present application is a non-provisional of and claims the benefit and priority under 35 U.S.C. 119(e) of the following applications, the entire contents of which are incorporated herein by reference for all purposes:

- (1) U.S. Provisional Application No. 61/698,413, filed Sep. 7, 2012, entitled TENANT AUTOMATION SYSTEM;
- (2) U.S. Provisional Application No. 61/698,459, filed Sep. 7, 2012, entitled SERVICE DEVELOPMENT INFRASTRUCTURE; and
- (3) U.S. Provisional Application No. 61/785,299, filed Mar. 14, 2013, entitled CLOUD INFRASTRUCTURE.

BACKGROUND

The present disclosure relates to computer systems and software, and more particularly to techniques for facilitating and automating the provision of services in a cloud environment.

Cloud computing is a model for enabling convenient, on-demand network access to a shared pool of configurable computing resources (e.g., networks, servers, storage, applications, and services). The services provided or accessed through the cloud (or network) are referred to as cloud services. There is a lot of processing that needs to be performed by a cloud service provider to make cloud services available to a subscribing customer. Due to its complexity, much of this processing is still done manually. For example, provisioning resources for providing such cloud services can be a very labor intensive process.

SUMMARY

Certain embodiments of the present invention provide techniques for automating the provisioning, managing and tracking of services provided by a cloud infrastructure system. In one embodiment, the cloud infrastructure system stores subscription order information related to one or more services subscribed to by a customer in the cloud infrastructure system.

In one embodiment, when a subscription order from a customer is received, cloud infrastructure system performs several processing steps before the services requested by the order are usable by the customer. These processing steps may involve verifying the order that may in turn require getting additional information from the customer, provisioning resources for providing one or more requested services, creating identity domains to ensure security for the customer data, and the like. Many of these processing steps may take some time to be performed. However, the customer typically wants to start using the ordered services as soon as possible. In certain embodiments, techniques for automating the provisioning, managing and tracking of services provided by cloud infrastructure system include providing the customer with the ability to gain access to services requested in the subscription order upon placing the subscription order and without the customer having to wait until all the steps involved in processing the subscription order are complete.

Some embodiments relate to a method for determining a workflow for processing a customer's subscription order. The method includes storing subscription order information related to a subscription order ordering services from a set of

2

services provided by the cloud infrastructure system. The method then includes identifying, based upon the subscription order information, a primary order workflow for processing the subscription order. The primary order workflow comprises one or more steps to be performed prior to enabling use of the ordered services. The method then includes identifying, based upon the subscription order information, a secondary order workflow for processing the subscription order. The secondary order workflow comprises one or more steps to be performed for processing the subscription order. Then, the method includes enabling access to the ordered services after completion of execution of the primary order workflow. In one embodiment, access is enabled before completion of execution of the steps in the secondary order workflow.

BRIEF DESCRIPTION OF THE DRAWINGS

Illustrative embodiments of the present invention are described in detail below with reference to the following drawing figures:

FIG. 1A is a logical view of a cloud infrastructure system according to one embodiment of the present invention.

FIG. 1B is a simplified block diagram of a hardware/software stack that may be used to implement a cloud infrastructure system according to an embodiment of the present invention.

FIG. 2 is a simplified block diagram of a system environment for implementing the cloud infrastructure system shown in FIG. 1A.

FIG. 3A depicts a simplified flowchart 300 depicting processing that may be performed by the TAS module in the cloud infrastructure system, in accordance with an embodiment of the present invention.

FIG. 3B depicts a simplified high level diagram of one or more sub-modules in the TAS module in the cloud infrastructure system, in accordance with an embodiment of the present invention.

FIG. 4 depicts an exemplary distributed deployment of the TAS component, according to an embodiment of the present invention.

FIG. 5 is a simplified block diagram illustrating the interactions of the SDI module with one or more modules in the cloud infrastructure system, in accordance with an embodiment of the present invention.

FIG. 6 depicts a simplified high level diagram of sub-modules of the SDI module according to an embodiment of the present invention.

FIG. 7A depicts a simplified flowchart depicting processing that may be performed by the SDI component in the cloud infrastructure system, in accordance with an embodiment of the present invention.

FIG. 7B depicts a simplified block diagram showing the high-level architecture of a Nuviaq system 710 and its relationships with other cloud infrastructure components according to an embodiment of the present invention.

FIG. 7C depicts an example sequence diagram illustrating steps of a provisioning process using a Nuviaq system according to an embodiment of the present invention.

FIG. 7D depicts an example sequence diagram illustrating steps of a deployment process using a Nuviaq system according to an embodiment of the present invention.

FIG. 7E depicts an example of database instances provisioned for a database service according to an embodiment of the present invention.

FIG. 8 is a high level block diagram of a system for processing a customer's subscription order, in accordance with one embodiment of the invention.

3

FIG. 9A depicts a simplified flowchart depicting processing that may be performed by the order workflow identification module in the TAS module to process a subscription order using primary and secondary order workflows, in accordance with an embodiment of the present invention.

FIG. 9B discusses an example of how one or more secondary steps in a secondary order workflow may be executed in relationship with one or more primary steps in a primary order workflow to process a customer's subscription order according to an embodiment of the present invention.

FIG. 9C is a high level flowchart illustrating a method for executing steps for processing a subscription order using a primary order workflow in accordance with one embodiment of the present invention.

FIG. 10 is a simplified block diagram of a computing system 1000 that may be used in accordance with embodiments of the present invention.

DETAILED DESCRIPTION

In the following description, for the purposes of explanation, specific details are set forth in order to provide a thorough understanding of embodiments of the invention. However, it will be apparent that various embodiments may be practiced without these specific details. The figures and description are not intended to be restrictive.

Certain embodiments of the present invention provide techniques for automating the provisioning, managing and tracking of services provided by a cloud infrastructure system.

In certain embodiments, a cloud infrastructure system may include a suite of applications, middleware and database service offerings that are delivered to a customer in a self-service, subscription-based, elastically scalable, reliable, highly available, and secure manner. An example of such a cloud infrastructure system is the Oracle Public Cloud provided by the present assignee.

A cloud infrastructure system may provide many capabilities including, but not limited to, provisioning, managing and tracking a customer's subscription for services and resources in the cloud infrastructure system, providing predictable operating expenses to customers utilizing the services in the cloud infrastructure system, providing robust identity domain separation and protection of a customer's data in the cloud infrastructure system, providing customers with a transparent architecture and control of the design of the cloud infrastructure system, providing customers assured data protection and compliance with data privacy standards and regulations, providing customers with an integrated development experience for building and deploying services in the cloud infrastructure system and providing customers with a seamless integration between business software, middleware, database and infrastructure services in the cloud infrastructure system.

In certain embodiments, services provided by the cloud infrastructure system may include a host of services that are made available to users of the cloud infrastructure system on demand such as online data storage and backup solutions, Web-based e-mail services, hosted office suites and document collaboration services, database processing, managed technical support services and the like. Services provided by the cloud infrastructure system can dynamically scale to meet the needs of its users. A specific instantiation of a service provided by cloud infrastructure system is referred to herein as a service instance. In general, any service made available to a user via a communication network such as the Internet from a cloud service provider's system is referred to as a cloud service. Typically, in a public cloud environment, servers and

4

systems that make up the cloud service provider's system are different from the customer's own on-premises servers and systems. For example, a cloud service provider's system may host an application and a user may, via a communication network such as the Internet, on demand, order and use the application.

A service in a computer network cloud infrastructure includes protected computer network access to storage, a hosted database, a hosted web server, a software application, or other service provided by a cloud vendor to a user, or as otherwise known in the art. For example, a service can include password-protected access to remote storage on the cloud through the Internet. As another example, a service can include a web service-based hosted relational database and script-language middleware engine for private use by a networked developer. As another example, a service can include access to an email software application hosted on a cloud vendor's web site.

FIG. 1A is a logical view of a cloud infrastructure system according to one embodiment of the present invention. Cloud infrastructure system 100 may provide a variety of services via a cloud or networked environment. These services may include one or more services provided under Software as a Service (SaaS) category, Platform as a Service (PaaS) category, Infrastructure as a Service (IaaS) category, or other categories of services including hybrid services. A customer, via a subscription order, may order one or more services provided by cloud infrastructure system 100. Cloud infrastructure system 100 then performs processing to provide the services in the customer's subscription order.

Cloud infrastructure system 100 may provide the cloud services via different deployment models. For example, services may be provided under a public cloud model where cloud infrastructure system 100 is owned by an organization selling cloud services (e.g., owned by Oracle) and the services are made available to the general public or different industry enterprises. As another example, services may be provided under a private cloud model where cloud infrastructure system 100 is operated solely for a single organization and may provide services for one or more entities within the organization. The cloud services may also be provided under a community cloud model where cloud infrastructure system 100 and the services provided by system 100 are shared by several organizations in a related community. The cloud services may also be provided under a hybrid cloud model, which is a combination of two or more different models.

As shown in FIG. 1A, cloud infrastructure system 100 may comprise multiple components, which working in conjunction, enable provision of services provided by cloud infrastructure system 100. In the embodiment illustrated in FIG. 1A, cloud infrastructure system 100 includes a SaaS platform 102, a PaaS platform 104, an IaaS platform 110, infrastructure resources 106, and cloud management functionality 108. These components may be implemented in hardware, or software, or combinations thereof.

SaaS platform 102 is configured to provide cloud services that fall under the SaaS category. For example, SaaS platform 102 may provide capabilities to build and deliver a suite of on-demand applications on an integrated development and deployment platform. SaaS platform 102 may manage and control the underlying software and infrastructure for providing the SaaS services. By utilizing the services provided by SaaS platform 102, customers can utilize applications executing on cloud infrastructure system 100. Customers can acquire the application services without the need for customers to purchase separate licenses and support.

5

Various different SaaS services may be provided. Examples include without limitation services that provide solutions for sales performance management, enterprise integration and business flexibility for large organizations, and the like. In one embodiment, the SaaS services may include Customer Relationship Management (CRM) services **110** (e.g., Fusion CRM services provided by the Oracle cloud), Human Capital Management (HCM)/Talent Management services **112**, and the like. CRM services **110** may include services directed to reporting and management of a sales activity cycle to a customer, and others. HCM/Talent services **112** may include services directed to providing global workforce lifecycle management and talent management services to a customer.

Various different PaaS services may be provided by PaaS platform **104** in a standardized, shared and elastically scalable application development and deployment platform. Examples of PaaS services may include without limitation services that enable organizations (such as Oracle) to consolidate existing applications on a shared, common architecture, as well as the ability to build new applications that leverage the shared services provided by the platform. PaaS platform **104** may manage and control the underlying software and infrastructure for providing the PaaS services. Customers can acquire the PaaS services provided by cloud infrastructure system **100** without the need for customers to purchase separate licenses and support. Examples of PaaS services include without limitation Oracle Java Cloud Service (JCS), Oracle Database Cloud Service (DBCS), and others.

By utilizing the services provided by PaaS platform **104**, customers can utilize programming languages and tools supported by cloud infrastructure system **100** and also control the deployed services. In some embodiments, PaaS services provided by the cloud infrastructure system **100** may include database cloud services **114**, middleware cloud services (e.g., Oracle Fusion Middleware services) **116** and Java cloud services **117**. In one embodiment, database cloud services **114** may support shared service deployment models that enable organizations to pool database resources and offer customers a database-as-a-service in the form of a database cloud, middleware cloud services **116** provides a platform for customers to develop and deploy various business applications and Java cloud services **117** provides a platform for customers to deploy Java applications, in the cloud infrastructure system **100**. The components in SaaS platform **102** and PaaS platform **104** illustrated in FIG. 1A are meant for illustrative purposes only and are not intended to limit the scope of embodiments of the present invention. In alternate embodiments, SaaS platform **102** and PaaS platform **104** may include additional components for providing additional services to the customers of cloud infrastructure system **100**.

Various different IaaS services may be provided by IaaS platform **110**. The IaaS services facilitate the management and control of the underlying computing resources such as storage, networks, and other fundamental computing resources for customers utilizing services provided by the SaaS platform and the PaaS platform.

In certain embodiments, cloud infrastructure system **100** includes infrastructure resources **106** for providing the resources used to provide various services to customers of the cloud infrastructure system **100**. In one embodiment, infrastructure resources **106** includes pre-integrated and optimized combinations of hardware such as servers, storage and networking resources to execute the services provided by the PaaS platform and the SaaS platform.

In certain embodiments, cloud management functionality **108** provides comprehensive management of cloud services

6

(e.g., SaaS, PaaS, IaaS services) in the cloud infrastructure system **100**. In one embodiment, cloud management functionality **108** includes capabilities for provisioning, managing and tracking a customer's subscription received by the cloud infrastructure system **100**, and the like.

FIG. 1B is a simplified block diagram of a hardware/software stack that may be used to implement cloud infrastructure system **100** according to an embodiment of the present invention. It should be appreciated that implementation depicted in FIG. 1B may have other components than those depicted in FIG. 1B. Further, the embodiment shown in FIG. 1B is only one example of a cloud infrastructure system that may incorporate an embodiment of the invention. In some other embodiments, cloud infrastructure system **100** may have more or fewer components than shown in FIG. 1B, may combine two or more components, or may have a different configuration or arrangement of components. In certain embodiments, the hardware and software components are stacked so as to provide vertical integration that provides optimal performance.

Various types of users may interact with cloud infrastructure system **100**. These users may include, for example, end users **150** that can interact with cloud infrastructure system **100** using various client devices such as desktops, mobile devices, tablets, and the like. The users may also include developers/programmers **152** who may interact with cloud infrastructure system **100** using command line interfaces (CLIs), application programming interfaces (APIs), through various integrated development environments (IDEs), and via other applications. User may also include operations personnel **154**. These may include personnel of the cloud service provider or personnel of other users.

Application services layer **156** identifies various cloud services that may be offered by cloud infrastructure system **100**. These services may be mapped to or associated with respective software components **160** (e.g., Oracle WebLogic server for providing Java services, oracle database for providing database services, and the like) via a service integration and linkages layer **158**.

In certain embodiments, a number of internal services **162** may be provided that are shared by different components or modules of cloud infrastructure system **100** and by the services provided by cloud infrastructure system **100**. These internal shared services may include, without limitation, a security and identity service, an integration service, an enterprise repository service, an enterprise manager service, a virus scanning and white list service, a high availability, backup and recovery service, service for enabling cloud support in IDEs, an email service, a notification service, a file transfer service, and the like.

Runtime infrastructure layer **164** represents the hardware layer on which the various other layers and components are built. In certain embodiments, runtime infrastructure layer **164** may comprise one Oracle's Exadata machines for providing storage, processing, and networking resources. An Exadata machine may be composed of various database servers, storage Servers, networking resources, and other components for hosting cloud-services related software layers. In certain embodiments, the Exadata machines may be designed to work with Oracle Exalogic, which is an engineered system providing an assemblage of storage, compute, network, and software resources. The combination of Exadata and Exalogic provides a complete hardware and software engineered solution that delivers high-performance, highly available, scalable, secure, and a managed platform for providing cloud services.

FIG. 2 is a simplified block diagram of a system environment for implementing the cloud infrastructure system shown in FIG. 1A according to an embodiment of the present invention. In the illustrated embodiment, system environment 230 includes one or more client computing devices 224, 226 and 228 that may be used by users to interact with cloud infrastructure system 100. A client device may be configured to operate a client application such as a web browser, a proprietary client application (e.g., Oracle Forms), or some other application, which may be used by a user of the client device to interact with cloud infrastructure system 100 to utilize services provided by cloud infrastructure system 100.

It should be appreciated that cloud infrastructure system 100 depicted in FIG. 2 may have other components than those depicted in FIG. 2. Further, the embodiment shown in FIG. 2 is only one example of a cloud infrastructure system that may incorporate an embodiment of the invention. In some other embodiments, cloud infrastructure system 100 may have more or fewer components than shown in FIG. 2, may combine two or more components, or may have a different configuration or arrangement of components.

Client computing devices 224, 226 and 228 may be general purpose personal computers (including, by way of example, personal computers and/or laptop computers running various versions of Microsoft Windows and/or Apple Macintosh operating systems), cell phones or PDAs (running software such as Microsoft Windows Mobile and being Internet, e-mail, SMS, Blackberry, or other communication protocol enabled), workstation computers running any of a variety of commercially-available UNIX or UNIX-like operating systems (including without limitation the variety of GNU/Linux operating systems), or any other computing device. For example, client computing devices 224, 226 and 228 may be any other electronic device, such as a thin-client computer, Internet-enabled gaming system, and/or personal messaging device, capable of communicating over a network (e.g., network 232 described below). Although exemplary system environment 230 is shown with three client computing devices, any number of client computing devices may be supported. Other devices such as devices with sensors, etc. may interact with cloud infrastructure system 100.

A network 232 may facilitate communications and exchange of data between clients 224, 226 and 228 and cloud infrastructure system 100. Network 232 may be any type of network familiar to those skilled in the art that can support data communications using any of a variety of commercially-available protocols, including without limitation TCP/IP, SNA, IPX, AppleTalk, and the like. Merely by way of example, network 232 can be a local area network (LAN) such as an Ethernet network, a Token-Ring network and/or the like, a wide-area network, a virtual network, including without limitation a virtual private network (VPN), the Internet, an intranet, an extranet, a public switched telephone network (PSTN), an infra-red network, a wireless network (e.g., a network operating under any of the IEEE 802.1X suite of protocols, the Bluetooth protocol known in the art, and/or any other wireless protocol), and/or any combination of these and/or other networks.

Cloud infrastructure system 100 may comprise one or more computers and/or servers which may be general purpose computers, specialized server computers (including, by way of example, PC servers, UNIX servers, mid-range servers, mainframe computers, rack-mounted servers, etc.), server farms, server clusters, or any other appropriate arrangement and/or combination. The computing devices that make up cloud infrastructure system 100 may run any of operating systems or a variety of additional server applica-

tions and/or mid-tier applications, including HTTP servers, FTP servers, CGI servers, Java servers, database servers, and the like. Exemplary database servers include without limitation those commercially available from Oracle, Microsoft, Sybase, IBM and the like.

In various embodiments, cloud infrastructure system 100 may be adapted to automatically provision, manage and track a customer's subscription to services offered by cloud infrastructure system 100. In one embodiment, as depicted in FIG. 2, the components in cloud infrastructure system 100 include an Identity Management (IDM) module 200, a services module 202, a Tenant Automation System (TAS) module 204, a Service Deployment Infrastructure (SDI) module 206, an Enterprise Manager (EM) module 208, one or more front-end web interfaces such as a store user interface (UI) 210, a cloud user interface (UI) 212, and a support user interface (UI) 216, an order management module 214, sales personnel 218, operator personnel 220 and an order database 224. These modules may include or be provided using one or more computers and/or servers which may be general purpose computers, specialized server computers, server farms, server clusters, or any other appropriate arrangement and/or combination. In one embodiment, one or more of these modules can be provided by cloud management functionality 108 or IaaS platform 110 in cloud infrastructure system 100. The various modules of the cloud infrastructure system 100 depicted in FIG. 2 are meant for illustrative purposes only and are not intended to limit the scope of embodiments of the present invention. Alternative embodiments may include more or fewer modules than those shown in FIG. 2.

In an exemplary operation, at (1) a customer using a client device such as client device 224 or 226 may interact with cloud infrastructure system 100 by browsing the various services provided by cloud infrastructure system 100 and placing an order for a subscription for one or more services offered by cloud infrastructure system 100. In certain embodiments, the customer may access store UI 210 or cloud UI 212 and place a subscription order via these user interfaces.

The order information received by cloud infrastructure system 100 in response to the customer placing an order may include information identifying the customer and one or more services offered by the cloud infrastructure system 100 that the customer intends to subscribe to. A single order may include orders for multiple services. For instance, a customer may login to cloud UI 212 and request a subscription for a CRM service and a Java cloud service in the same order.

Additionally, the order may also include one or more service levels for the ordered services. As used herein, and as will be discussed in greater detail below, a service level for a service determines the amount of resources to be allocated for providing the requested service in the context of the subscription, such as the amount of storage, amount of computing resources, data transfer facilities, and the like. For example, a basic service level may provide a minimum level of storage, data transmission, or number of users, and higher service levels may include additional resources.

In addition, in some instances, the order information received by cloud infrastructure system 100 may include information indicative of a customer level, and the time period during which the service is desired. The customer level specifies the priority of the customer making the subscription request. In one example, the priority may be determined based on the quality of service that the cloud infrastructure system 100 guarantees or promises the customer as specified by a Service Level Agreement (SLA) agreed to between the customer and the provider of the cloud services. In one

example, the different customer levels include a basic level, a silver level and a gold level. The time period for a service may specify the start date and time for the service and the time period for which the service is desired (e.g., a service end date and time may be specified).

In one embodiment, a customer may request a new subscription via store UI **210** or request for a trial subscription via cloud UI **212**. In certain embodiments, store UI **210** may represent the service provider's eCommerce store front (e.g., www.oracle.com/store for Oracle Cloud services). Cloud UI **212** may represent a business interface for the service provider. Consumer can explore available services and sign up for interested services through cloud UI **212**. Cloud UI **212** captures user input necessary for ordering trial subscriptions provided by cloud infrastructure system **100**. Cloud UI **212** may also be used to view account features and configure the runtime environment located within cloud infrastructure system **100**. In addition to placing an order for a new subscription, store UI **210** may also enable the customer to perform other subscription-related tasks such as changing the service level of a subscription, extending the term of the subscription, increasing the service level of a subscription, terminating an existing subscription, and the like.

After an order has been placed per (1), at (2), the order information that is received via either store UI **210** or cloud UI **212** is stored in order database **224**, which can be one of several databases operated by cloud infrastructure system **100** and utilized in conjunction with other system elements. While order database **224** is shown logically as a single database in FIG. 2, in actual implementation, this may comprise one or more databases.

At (3), the order is forwarded to order management module **214**. Order management module **214** is configured to perform billing and accounting functions related to the order such as verifying the order and upon verification, booking the order. In certain embodiments, order management module **214** may include a contract management module and an install base module. The contract management module may store contract information associated with the customer's subscription order such as the customer's service level agreement (SLA) with cloud infrastructure system **100**. The install base module may include detailed descriptions of the services in the customer's subscription order. In addition to order information, the install base module may track installation details related to the services, product status and support service history related to the services. As a customer orders new services or upgrades existing ones, the install base module may automatically add new order information.

At (4), information regarding the order is communicated to TAS module **204**. In one embodiment, TAS module **204** utilizes the order information to orchestrate the provisioning of services and resources for the order placed by the customer. At (5), TAS component **204** orchestrates the provisioning of resources to support the subscribed services using the services of SDI module **206**. At (6) TAS module **204** provides information related to the provisioned order received from SDI module **206** to services module **202**. In some embodiments, at (7), SDI module **206** may also use services provided by services module **202** to allocate and configure the resources needed to fulfill the customer's subscription order.

At (8), services module **202** sends a notification to the customers on client devices **224**, **226** and **228** regarding the status of the order.

In certain embodiments, TAS module **204** functions as an orchestration component that manages business processes associated with each order and applies business logic to determine whether an order should proceed to provisioning. In one

embodiment, upon receiving an order for a new subscription, TAS module **204** sends a request to SDI module **206** to allocate resources and configure those resources needed to fulfill the subscription order. SDI module **206** enables the allocation of resources for the services ordered by the customer. SDI module **206** provides a level of abstraction between the cloud services provided by cloud infrastructure system **100** and the physical implementation layer that is used to provision the resources for providing the requested services. TAS module **204** may thus be isolated from implementation details such as whether or not services and resources are actually provisioned on the fly or pre-provisioned and only allocated/assigned upon request.

In certain embodiments, a user may use store UI **210** to directly interact with order management module **214** to perform billing and accounting related functions such as verifying the order and upon verification, booking the order. In some embodiments, instead of a customer placing an order, at (9), the order may instead be placed by sales personnel **218** on behalf of the customer such as a customer's service representative or sales representative. Sales personnel **218** may directly interact with order management module **214** via a user interface (not shown in FIG. 2) provided by order management module **214** for placing orders or for providing quotes for the customer. This, for example, may be done for large customers where the order may be placed by the customer's sales representative through order management module **214**. The sales representative may set up the subscription on behalf of the customer.

EM module **208** is configured to monitor activities related to managing and tracking a customer's subscription in cloud infrastructure system **100**. EM module **208** collects usage statistics for the services in the subscription order such as the amount of storage used, the amount data transferred, the number of users, and the amount of system up time and system down time. At (10), a host operator personnel **220**, who may be an employee of a provider of cloud infrastructure system **100**, may interact with EM module **208** via an enterprise manager user interface (not shown in FIG. 2) to manage systems and resources on which services are provisioned within cloud infrastructure system **100**.

Identity management (IDM) module **200** is configured to provide identity services such as access management and authorization services in cloud infrastructure system **100**. In one embodiment, IDM module **200** controls information about customers who wish to utilize the services provided by cloud infrastructure system **100**. Such information can include information that authenticates the identities of such customers and information that describes which actions those customers are authorized to perform relative to various system resources (e.g., files, directories, applications, communication ports, memory segments, etc.) IDM module **200** can also include the management of descriptive information about each customer and about how and by whom that descriptive information can be accessed and modified.

In one embodiment, information managed by the identity management module **200** can be partitioned to create separate identity domains. Information belonging to a particular identity domain can be isolated from all other identity domains. Also, an identity domain can be shared by multiple separate tenants. Each such tenant can be a customer subscribing to services in the cloud infrastructure system **100**. In some embodiments, a customer can have one or many identity domains, and each identity domain may be associated with one or more subscriptions, each subscription having one or many services. For example, a single customer can represent a large entity and identity domains may be created for divi-

11

sions/departments within this large entity. EM module **208** and IDM module **200** may in turn interact with order management module **214** at (11) and (12) respectively to manage and track the customer's subscriptions in cloud infrastructure system **100**.

In one embodiment, at (13), support services may also be provided to the customer via a support UI **216**. In one embodiment, support UI **216** enables support personnel to interact with order management module **214** via a support backend system to perform support services at (14). Support personnel in the cloud infrastructure system **100** as well as customers can submit bug reports and check the status of these reports via support UI **216**.

Other interfaces, not shown in FIG. **2** may also be provided by cloud infrastructure system **100**. For example, an identity domain administrator may use a user interface to IDM module **200** to configure domain and user identities. In addition, customers may log into a separate interface for each service they wish to utilize. In certain embodiments, a customer who wishes to subscribe to one or more services offered by cloud infrastructure system **100** may also be assigned various roles and responsibilities. In one embodiment, the different roles and responsibilities that may be assigned for a customer may include that of a buyer, an account administrator, a service administrator, an identity domain administrator or a user who utilizes the services and resources offered by cloud infrastructure system **100**. The different roles and responsibilities are described more fully in FIG. **4** below.

FIG. **3A** depicts a simplified flowchart **300** depicting processing that may be performed by the TAS module in the cloud infrastructure system, in accordance with an embodiment of the present invention. The processing depicted in FIG. **3A** may be implemented in software (e.g., code, instructions, program) executed by one or more processors, hardware, or combinations thereof. The software may be stored in memory (e.g., on a memory device, on a non-transitory computer-readable storage medium). The particular series of processing steps depicted in FIG. **3A** is not intended to be limiting. Other sequences of steps may also be performed according to alternative embodiments. For example, alternative embodiments of the present invention may perform the steps outlined above in a different order. Moreover, the individual steps illustrated in FIG. **3A** may include multiple sub-steps that may be performed in various sequences as appropriate to the individual step. Furthermore, additional steps may be added or removed depending on the particular applications. One of ordinary skill in the art would recognize many variations, modifications, and alternatives. In one embodiment, the processing depicted in FIG. **3A** may be performed by one or more components in TAS component **204** as will be described in detail in FIG. **3B**.

At **302**, a customer's subscription order is processed. The processing may include validating the order, in one example. Validating the order includes ensuring that the customer has paid for the subscription and ensuring that the customer does not already have subscriptions with the same name or that the customer is not attempting to create multiple subscriptions of the same type in the same identity domain for subscription types for which this is disallowed (such as, in the case of a CRM service). Processing may also include tracking the status of an order for each order that is being processed by cloud infrastructure system **100**.

At **304**, a business process associated with the order is identified. In some instances, multiple business processes may be identified for an order. Each business process identifies a series of steps for processing various aspects of the order. As an example, a first business process may identify

12

one or more steps related to provisioning physical resources for the order, a second business process may identify one or more steps related to creating an identity domain along with customer identities for the order, a third business process may identify one or more steps for related to performing back office functions such as creating a customer record for the user, performing accounting functions related to the order, and the like. In certain embodiments, different business processes may also be identified for processing different services in an order. For example, different business process may be identified to process a CRM service and a database service.

At **306**, the business process identified for the order in **304** is executed. Executing the business process associated with the order may include orchestrating the series of steps associated with the business process identified in step **304**. For example, executing a business process related to provisioning physical resources for the order may include sending a request to SDI module **206** to allocate resources and configure those resources needed to fulfill the subscription order.

At **308**, a notification is sent to the customer regarding the status of the provisioned order. Additional description related to performing steps **302**, **304**, **306** and **308** is provided in detail in FIG. **3B**.

FIG. **3B** depicts a simplified high level diagram of one or more sub-modules in the TAS module in the cloud infrastructure system, in accordance with an embodiment of the present invention. In one embodiment, the modules depicted in FIG. **3B** perform the processing described in steps **302-308** discussed in FIG. **3A**. In the illustrated embodiment, TAS module **204** comprises an order processing module **310**, a business process identifier **312**, a business process executor **316**, an overage framework **322**, a workflow identification module **324**, and a bundled subscription generator module **326**. These modules may be implemented in hardware, or software, or combinations thereof. The various modules of the TAS module depicted in FIG. **3B** are meant for illustrative purposes only and are not intended to limit the scope of embodiments of the present invention. Alternative embodiments may include more or fewer modules than those shown in FIG. **3B**.

In one embodiment, order processing module **310** receives an order from a customer from one or more input sources **321**. For example, order processing module **310** may directly receive an order via cloud UI **212** or store UI **210**, in one embodiment. Alternatively, order processing module **310** may receive an order from order management module **214** or order database **224**. Order processing module **310** then processes the order. In certain embodiments, processing the order includes generating a customer record which includes information about the order such as a service type, a service level, a customer level, the type of resources, the amount of the resources to be allocated to the service instance and a time period during which the service is desired. As part of the processing, order processing module **310** also determines whether the order is a valid order. This includes ensuring that the customer does not already have subscriptions with the same name or that the customer is not attempting to create multiple subscriptions of the same type in the same identity domain for subscription types where this is disallowed (such as, in the case of a fusion CRM service).

Order processing module **310** may also perform additional processing on the order. Processing may include tracking the status of an order for each order that is being processed by cloud infrastructure system **100**. In one embodiment, order processing module **310** may process each order to identify a number of states pertaining to the order. In one example, the different states of an order may be an initialized state, a provisioned state, an active state, an administration required

13

state, an error state, and the like. An initialized state refers to the state of a new order; a provisioned state refers to the state of an order once the services and resources for the order have been provisioned. An order is in an active state when the order has been processed by TAS module **204** and a notification to that effect has been delivered to the customer. An order is in an administration required state when intervention by an administrator is needed to resolve the issue. The order is in an error state when the order cannot be processed. In addition to maintaining the order progress status, order processing module **310** also maintains detailed information about any failures encountered during process execution. In other embodiments, and as will be discussed in detail below, the additional processing performed by order processing module **310** may also include changing the service level for a service in the subscription, changing the services included in the subscription, extending the time period of the subscription, and canceling the subscription or specifying different service levels for different time periods in the subscription.

After an order has been processed by order processing module **310**, business logic is applied to determine whether the order should proceed to provisioning. In one embodiment, as part of orchestrating the order, business process identifier **312** receives the processed order from order processing module **310** and applies business logic to identify a particular business process to use for the order being processed. In one embodiment, business process identifier **312** may utilize information stored in a service catalog **314** to determine the particular business process to be used for the order. In one embodiment, and as discussed in FIG. 3A, multiple business processes may be identified for an order and each business process identifies a series of steps for processing various aspects of the order. In another embodiment, and as discussed above, different business processes may be defined for different types of services, or combinations of services such as a CRM service or a database service. In one embodiment, service catalog **314** may store information mapping an order to a particular type of business process. Business process identifier **312** may use this information to identify a specific business process for the order being processed.

Once a business process has been identified, business process identifier **312** communicates the particular business process to be executed to business process executor **316**. Business process executor **316** then executes steps of the identified business process by operating in conjunction with one or more modules in the cloud infrastructure system **100**. In some embodiments, business process executor **316** acts as an orchestrator for performing the steps associated with a business process. For example, the business process executor may interact with order processing module **310** to execute steps in a business process that identifies workflows related to the order, determines the overage of services in the order or identifies service components related to the order.

In one example, business process executor **316** interacts with SDI module **206** to execute steps in a business process for allocating and provisioning resources for services requested in the subscription order. In this example, for each step in the business process, business process executor **316** may send a request to SDI component **206** to allocate resources and configure resources needed to fulfill the particular step. SDI component **206** is responsible for the actual allocation of the resources. Once all the steps of the business processes of an order have been executed, business process executor **316** may send a notification to the customer of the processed order by utilizing the services of services component **202**. The notification may include sending an email notification to the customer with details of the processed

14

order. The email notification may also include deployment information related to the order to enable the customer to access the subscribed services.

In certain embodiments, TAS module **204** may provide one or more TAS Application Programming Interfaces (APIs) **318** that enable TAS module **204** to interact with other modules in cloud infrastructure system **100** and for other modules to interact with TAS module **204**. For example, the TAS APIs may include a system provisioning API that interacts with SDI module **206** via an asynchronous Simple Object Access Protocol (SOAP) based web services call to provision resources for the customer's subscription order. In one embodiment, TAS module **204** may also utilize the system provisioning API to accomplish system and service instance creation and deletion, switch a service instance to an increased service level, and associate service instances. An example of this is the association of a Java service instance to a fusion applications service instance to allow secure web service communications. The TAS APIs may also include a notification API that interacts with the services module **202** to notify the customer of a processed order. In certain embodiments, the TAS module **204** also periodically propagates subscription information, outages, and notifications (e.g. planned downtime) to services component **202**.

In certain embodiments, TAS module **204** periodically receives usage statistics for each of the provisioned services such as the amount of storage used, the amount data transferred, the number of users, and the amount of system up time and system down time from EM module **208**. Overage framework **322** utilizes the usage statistics to determine whether over use of a service has occurred, and if so, to determine how much to bill for the overage, and provides this information to order management module **214**.

In certain embodiments, TAS module **204** includes an order workflow identification module **324** that is configured to identify one or more workflows associated with processing a customer's subscription order. In certain embodiments, TAS module **204** may include a subscription order generation framework **326** for generating subscription orders for a customer when the customer places a subscription order for one or more services offered by the cloud infrastructure system **100**. In one embodiment, a subscription order includes one or more service components responsible for providing the services requested by a customer in the subscription order.

Additionally, TAS module **204** may also interact with one or more additional databases such as a Tenant Information System (TIS) database **320** to enable the provisioning of resources for one or more services subscribed by the customer while taking into consideration historical information, if any, available for the customer. TIS database **320** may include historical order information and historical usage information pertaining to orders subscribed by the customer.

TAS module **204** may be deployed using different deployment models. In certain embodiments, the deployment includes a central component that interfaces with one or more distributed components. The distributed components may, for example, be deployed as various data centers and accordingly may also be referred to as data center components. The central component includes capabilities to process orders and coordinate services in cloud infrastructure system **100**, while the data center components provide capabilities for provisioning and operating the runtime system that provides the resources for the subscribed services.

FIG. 4 depicts an exemplary distributed deployment of the TAS module, according to an embodiment of the present invention. In the embodiment depicted in FIG. 4, the distributed deployment of TAS module **204** includes a TAS central

15

component **400** and one or more TAS Data Centers (DCs) components **402**, **404** and **406**. These components may be implemented in hardware, or software, or combinations thereof.

In one embodiment, the responsibilities of TAS central component **400** include, without limitation, to provide a centralized component for receiving customer orders, performing order-related business operations such as creating a new subscription, changing the service level for a service in the subscription, changing the services included in the subscription, and extending the time period of the subscription, or canceling the subscription. The responsibilities of TAS central component **400** may also include maintaining and serving subscription data needed by cloud infrastructure system **100** and interfacing with order management module **214**, support UI **216**, cloud UI **212** and store UI **210** to handle all the back-office interactions.

In one embodiment, the responsibilities of TAS DCs **402**, **404** and **406** include, without limitation, performing runtime operations for orchestrating the provisioning the resources for one or more services subscribed by the customer. TAS DCs **402**, **404** and **406** also include capabilities to perform operations such as locking, unlocking, enabling, or disabling a subscription order, collecting metrics related to the order, determining the status of the order, and sending notification events related to the order.

In an exemplary operation of the distributed TAS system shown in FIG. 4, TAS central component **400** initially receives an order from a customer via cloud UI **212**, store UI **210**, via order management system **214**, or via order database **224**. In one embodiment, the customer represents a buyer who has financial information and the authority to order and/or change a subscription. In one embodiment, the order information includes information identifying the customer, the type of services that the customer wishes to subscribe to, and an account administrator who will be responsible for handling the request. In certain embodiments, the account administrator may be nominated by the customer when the customer places an order for a subscription to one or more services offered by cloud infrastructure system **100**. Based on the order information, the TAS central component **400** identifies the data region of the world such as Americas, EMEA, or Asia Pacific in which the order originates and the particular TAS DCs (for e.g., **402**, **404** or **406**) that will be deployed for provisioning the order. In one embodiment, the particular TAS DC (for e.g., from among DCs **402**, **404** or **406**) that will be deployed for provisioning the order is determined based on the geographical data region in which the request originated.

TAS central component **400** then sends the order request to the particular TAS DC in which to provision services for the order request. In one embodiment, TAS DCs **402**, **404** or **406** identify a service administrator and an identity domain administrator responsible for processing the order request at the particular TAS DC. The service administrator and the identity administrator may be nominated by the account administrator identified in the subscription order. TAS DCs **402**, **404** or **406** communicate with SDI module **204** to orchestrate the provisioning of physical resources for the order. SDI component **204** in respective TAS DCs **402**, **404** or **406** allocates resources and configures those resources needed to fulfill the subscription order.

In certain embodiments, TAS DCs, **402**, **404** or **406** identify an identity domain associated with the subscription. SDI component **206** may provide the identity domain information to IDM component **200** (shown in FIG. 2) for identifying an existing identity domain or creating a new identity domain. Once the order is provisioned by the SDI module at respective

16

TAS DCs, **402**, **404** or **406**, TAS central component **400** may place information regarding the provisioned resources in a support system, via support UI **216**. Information may include, for example, displaying resource metrics related to the services and usage statistics of the services.

Once in operation, at each data center, EM module **208** to periodically collects usage statistics for each of the provisioned services provisioned at that data center, such as the amount of storage used, the amount data transferred, the number of users, and the amount of system up time and system down time. These statistics are provided to the TAS DC that is local to EM module **208** (i.e., at the same data center). In an embodiment, the TAS DCs may use the usage statistics to determine whether overuse of a service has occurred, and if so, to determine how much to bill for the overage, and provide the billing information to order management system **214**.

FIG. 5 is a simplified block diagram illustrating the interactions of the SDI module with one or more modules in the cloud infrastructure system, in accordance with an embodiment of the present invention. In one embodiment, SDI module **206** interacts with TAS module **204** to provision resources for services in a subscription order received by TAS module **204**. In certain embodiments, one or more of the modules illustrated in FIG. 5 may be modules within cloud infrastructure system **100**. In other embodiments, one or more of the modules that interact with SDI module **206** may be outside cloud infrastructure system **100**. In addition, alternative embodiments may have more or less modules than those shown in FIG. 5. These modules may be implemented in hardware, or software, or combinations thereof.

In one embodiment, the modules in SDI module **206** may include one or more modules in SaaS platform **102** and PaaS platform **104** in cloud infrastructure system **100**. In order to perform provisioning of resources for various services, SDI module **206** may interact with various other modules, each customized to help with provisioning resources for a particular type of service. For example, as illustrated in FIG. 5, SDI module **206** may interact with a Java service provisioning control module **500** to provision Java cloud services. In one embodiment, Java service provisioning control component **500** may deploy a Java Cloud Service (JCS) assembly specified by SDI module **206** that includes a set of tasks to be performed to provision Java cloud services. Infrastructure resources **106** then determines the resources needed to provision the Java cloud services.

As other examples, SDI module **206** may interact with one or more modules such as a Virtual Assembly Builder (VAB) module **502**, an Application Express (APEX) deployer module **504**, a Virtual Machine (VM) module **506**, an IDM module **200**, and a database machine module **118**. VAB module **502** includes capabilities to configure and provision complete multi-tier application environments. In one embodiment, VAB module **502** deploys a Middleware (MW) service assembly specified by SDI module **206** to provision a MW service in cloud infrastructure system **100** using the services provided by VM module **506**. APEX deployer module **504** includes capabilities to configure and provision database services. In one embodiment, APEX deployer module **504** deploys a database service assembly specified by SDI module **206** to provision a database service in cloud infrastructure system **100** using the resources provided by infrastructure resources **106**. SDI module **206** interacts with IDM module **200** to provide identity services such as access management across multiple applications in cloud infrastructure system **100**.

FIG. 6 depicts a simplified high level diagram of sub-modules of the SDI module according to an embodiment of the present invention. In the embodiment depicted in FIG. 6, SDI module 206 includes a SDI-Web Services (WS) module 600, an SDI request controller module 602, an SDI task manager module 604, an SDI monitoring module 606, an SDI data access module 608, an SDI common library module 610, and an SDI connector module 612. These modules may be implemented in hardware, or software, or combinations thereof. SDI module 206 depicted in FIG. 6 and its various modules are meant for illustrative purposes only and are not intended to limit the scope of embodiments of the present invention. Alternative embodiments may have more or less modules than those shown in FIG. 6. These modules and their functions are described in detail below.

SDI-WS module 600 includes capabilities for receiving a step in the business associated with an order from business process executor 316 of TAS component 204. In one embodiment, SDI-WS module 600 parses each step of the business process and converts the step into an internal representation used by SDI module 206. In one embodiment, each step of the business process associated with the order arrives through a web service processing layer (for example, via System Provisioning API discussed in FIG. 3B) in the form of a SOAP request to SDI-WS module 600.

SDI request controller module 602 is the internal request processing engine in SDI module 206 and includes capabilities for performing asynchronous request processing, concurrent request processing, concurrent task processing, fault tolerant and recovery and plug-in support related to the order requests. In one embodiment, SDI request controller module 602 accepts each step of the business process associated with the order from SDI-WS module 600 and submits the step to SDI task manager module 604.

SDI task manager module 604 translates each step specified in the business process into a series of tasks for provisioning the particular step. Once the set of tasks for a specific step have been provisioned, SDI task manager module 604 responds to business process executor 316 in TAS module 204 with operation results that includes an order payload with details of the resources provisioned to fulfill the particular step. SDI task manager module 604 repeats this process until all the steps of the particular business process associated with the order are complete.

In certain embodiments, SDI task manager module 604 translates each step specified in the business process into a series of tasks by utilizing the services of SDI connector module 612. SDI connector module 612 includes one or more connectors for handling the deployment of tasks specified by SDI task manager module 604 to provision one or more services related to the order request. In certain embodiments, one or more of the connectors may handle tasks that are specific to a particular service type while other connectors may handle tasks that are common across different service types. In one embodiment, SDI connector module 612 includes a set of connectors (wrapper APIs) that interface with one or more of the external modules (shown in FIG. 5) in cloud infrastructure system 100 to provision the services and resources related to the order request. For example, Application Express (APEX) connector 614 interfaces with APEX deployer module 504 to provision database services. Web Center Connector 616 (WCC) interfaces with a web center module in cloud infrastructure system 100 to provision web services. The web center module is a user engagement platform and includes capabilities for delivering connectivity between people and information in cloud infrastructure system 100.

In certain embodiments, Middleware Applications (MA) connector 618 interfaces with VAB module 502 in cloud infrastructure system 100 to provision middleware application services. NUVIAQ connector 620 interfaces with VAB module 502 to provision Java services. IDM connector 622 interfaces with IDM module 200 to provide identity and access management for users subscribing to services and resources in cloud infrastructure system 100. Virtual Assembly Builder (VAB) connector 624 interfaces with VAB module 502 in cloud infrastructure system 100 to configure and provision complete multi-tier application environments. Plug-in connector 626 interfaces with EM module 208 to manage and monitor the components in cloud infrastructure system 100. HTTP server connector 628 interfaces with one or more web servers in the PaaS platform to provide connection services to users in cloud infrastructure system 100.

SDI monitoring module 606 in SDI module 206 provides an inbound interface for receiving Java Management Extensions (JMX) requests. SDI monitoring module 606 also provides tools for managing and monitoring applications, system objects and devices in cloud infrastructure system 100. SDI-data access module 608 provides an inbound interface for receiving Java Database Connectivity (JDBC) requests. SDI-data access module 608 supports data access and provides object relational mapping, java transaction API services, data access objects, and connection pooling in cloud infrastructure system 100. The SDI-common library module 610 provides configuration support for the modules in SDI module 206.

The embodiment of FIG. 6 discussed above describes modules in the SDI module according to an embodiment of the present invention. FIG. 7A depicts a simplified flowchart 700 depicting processing that may be performed by the modules of the SDI module in the cloud infrastructure system, in accordance with an embodiment of the present invention. The processing depicted in FIG. 7A may be implemented in software (e.g., code, instructions, program) executed by one or more processors, hardware, or combinations thereof. The software may be stored in memory (e.g., on a memory device, on a non-transitory computer-readable storage medium). The particular series of processing steps depicted in FIG. 7A is not intended to be limiting. Other sequences of steps may also be performed according to alternative embodiments. For example, alternative embodiments of the present invention may perform the steps outlined above in a different order. Moreover, the individual steps illustrated in FIG. 7A may include multiple sub-steps that may be performed in various sequences as appropriate to the individual step. Furthermore, additional steps may be added or removed depending on the particular applications. One of ordinary skill in the art would recognize many variations, modifications, and alternatives. In one embodiment, the processing depicted in FIG. 7A may be performed by one or more modules in the SDI module 206 discussed in detail in FIG. 6.

At 702, a business process associated with a subscription order is received. In one embodiment, SDI-WS module 600 in SDI module 206 receives one or more steps in the business process associated with the subscription order from business process executor 316. At 704, each step in the business process is translated into a series of tasks for provisioning resources for the subscription order. In one embodiment, SDI task manager module 604 in SDI module 206 translates each step specified in the business process into a series of tasks by utilizing the services of SDI connector module 612. At 706, the subscription order is provisioned based on the series of tasks. In one embodiment, and as discussed in FIG. 6, SDI connector module 612 includes one or more connectors for

handling the deployment of tasks specified by SDI task manager module **604** to provision resources for the services in the subscription order.

As described above with respect to FIG. 6, SDI task manager module **604** translates each step specified in a business process into a series of tasks by utilizing the services of SDI connector module **612**, which may include one or more connectors for handling the deployment of tasks specified by SDI task manager module **604** to provision one or more services related to the order request. One or more of the connectors may handle tasks that are specific to a particular service type while other connectors may handle tasks that are common across different service types. In one embodiment, SDI connector module **612** includes a set of connectors (wrapper APIs) that interface with one or more of the external modules (shown in FIG. 5) in cloud infrastructure system **100** to provision the services and resources related to the order request. For example, a NUVIAQ connector **620** interfaces with VAB module **502** to provision Java services.

FIG. 7B depicts a simplified block diagram showing the high-level architecture of a Nuviaq system **710** and its relationships with other cloud infrastructure components according to an embodiment of the present invention. It should be appreciated that Nuviaq system **710** depicted in FIG. 7B may have other components than those depicted in FIG. 7B. Further, the embodiment shown in FIG. 7B is only one example of a cloud infrastructure system that may incorporate an embodiment of the invention. In some other embodiments, Nuviaq system **710** may have more or fewer components than shown in FIG. 7B, may combine two or more components, or may have a different configuration or arrangement of components.

In certain embodiments, Nuviaq system **710** may be configured to provide a runtime engine for orchestrating PaaS operations. Nuviaq system **710** may provide a web service API to facilitate integration with other products and services. Nuviaq system **710** also provides support for complex workflows in system provisioning, application deployment and associated lifecycle operations and integrates with management and monitoring solutions.

In the embodiment depicted in FIG. 7B, Nuviaq system **710** comprises a Nuviaq proxy **712**, a Nuviaq manager **714**, and a Nuviaq database **716**. In certain embodiments, Nuviaq manager **714** provides an entry point into Nuviaq system **710**, providing secure access to PaaS operations via the web service API. Internally, it tracks system state in the database and controls job execution on the workflow engine. In a public cloud, Nuviaq manager **714** may be accessed by the Tenant Provisioning system (SDI **206**) and the Tenant Console, to drive provisioning and deployment operations respectively.

In one embodiment, Nuviaq manager **714** executes jobs asynchronously via an internal workflow engine. A job may be a sequence of actions specific to a given PaaS workflow. Actions may be performed in order, with failure in any step resulting in failure of the overall job. Many workflow actions delegate to external systems relevant to the workflow, such as the EM command line interface (cli). In one implementation, Nuviaq manager **714** application may be hosted in a 2-node WebLogic cluster with associated HTTP server (e.g., Oracle HTTP Server or OHS) instance, running inside a firewall.

In certain embodiments, Nuviaq proxy **712** is the public access point to the Nuviaq API. In one embodiment, only Public API may be exposed here. Requests received by proxy **712** may be forwarded to Nuviaq manager **714**. In one embodiment, Nuviaq proxy **712** runs outside the firewall, whereas manager **714** runs within the firewall. In one implementation, Nuviaq proxy **712** application runs on a WebLogic cluster running outside the firewall.

In certain embodiments, Nuviaq database **716** tracks various domain entities such as, without limitation, platform

instance, deployment plan, application, WebLogic domain, jobs, alerts, and the like. Primary keys may be aligned with the Service Database where appropriate.

In one embodiment, Platform Instance **718** may contain all resources required for a WebLogic service for a given tenant.

Nuviaq system **710** may rely on additional systems of cloud infrastructure system **100** to carry out the workflows used the WebLogic cloud service. These dependencies may include dependencies on SDI **206**, IDM **200**, a virus scan system, a service database, CRM instances, and the like. For example, Nuviaq system **710** may depend upon functions performed by an Assembly Deployer in SDI **206**. In one embodiment, the Assembly Deployer is a system to manage interactions with OVAB (Oracle Virtual Assembly Builder) and OVM (Oracle Virtual Machine). Capabilities of the Assembly Deployer used by Nuviaq system **710** may include, without limitation, functions for deploying an assembly, undeploying an assembly, describing assembly deployment, scaling appliance, and the like. In one implementation, Nuviaq system **710** accesses the Assembly Deployer via a web service API.

In certain embodiments, security policies may require certain artifacts to be scanned for viruses before being deployed to an application. Cloud infrastructure system **100** may provide a virus scan system for this purpose that provides scanning as a service for multiple components of the public cloud.

In certain embodiments, a public cloud infrastructure may maintain a Service Database containing information about tenants (e.g., customers) and their service subscriptions. Nuviaq workflows may access to this data in order to properly configure a WebLogic service as a client to other services that the tenant also subscribes to.

Nuviaq system **710** may depend on IDM **200** for its security integration. In certain embodiments, Java Service instances can be associated with a CRM instance. The association allows user applications deployed to their Java Service instance to access a CRM instance through Web Service calls.

Various entities may use services provided by Nuviaq system **710**. These clients of Nuviaq system **710** may include: a Tenant Console, which is an management server (e.g., Oracle Management Server) based user interface that customers may access to manage their applications on their platform instances; several IDEs such as Oracle IDEs (JDeveloper, NetBeans, and OEPE) have been extended to offer access to application lifecycle management operations; one or more Command Line Interfaces (CLIs) that are available to access lifecycle operations on the platform instances.

Provisioning use case for Nuviaq system **710**—A Provision Platform Instance use case is realized via the Create Platform Instance operation of the Nuviaq API. In the context of cloud infrastructure system **100**, a service instance with respect to the Nuviaq system corresponds to a Nuviaq platform instance. A platform instance is assigned a unique identifier is used on all subsequent operations related to this instance. A Platform Deployment descriptor provided to the Create Platform Instance action allows for properties to be set that modify the configuration of the platform instance to meet the subscription requirements of the tenant. These properties may include for example:

Property#1: oracle.cloud.service.weblogic.size

Values: BASIC, STANDARD, ENTERPRISE

Description: Specifies the subscription type. This impacts the number of servers, database limits and quality of service settings.

Property#2: oracle.cloud.service.weblogic.trial

Values: TRUE, FALSE

Description: Indicates whether or not this is a trial subscription.

Property#3: oracle.cloud.service.weblogic.crm

Values: CRM Service ID

21

Description: Identifies a CRM service to be associated with this WebLogic service instance.

FIG. 7C depicts an example sequence diagram illustrating steps of a provisioning process using a Nuviq system according to an embodiment of the present invention. The sequence diagram depicted in FIG. 7C is only an example and is not intended to be limiting.

Install/Update Application use case—The Install Application operation deploys an application to a running WebLogic Server after validating that the application archive meets the security requirements of the Public Cloud. In one embodiment, the Application Deployment descriptor provided to the Install Application action allows for properties to be set that modify the configuration of the application to meet the subscription requirements of the tenant. These properties may include for example:

Property: oracle.cloud.service.weblogic.state

Values: RUNNING, STOPPED

Description: Specifies the initial state of the application after deployment.

FIG. 7D depicts an example sequence diagram illustrating steps of a deployment process using a Nuviq system according to an embodiment of the present invention. The sequence diagram depicted in FIG. 7D is only an example and is not intended to be limiting.

Referring back to FIG. 2, in certain embodiments, TAS 204 and SDI 206 working in cooperation are responsible for provisioning resources for one or more services ordered by a customer from a set of services offered by cloud infrastructure system 100. For example, in one embodiment, for provisioning a database service, the automated provisioning flow may be as follows for a paid subscription:

(1) Customer places an order for a paid subscription to a service via Store UI 210.

(2) TAS 204 receives the subscription order.

(3) When services are available TAS 204 initiates provisioning by using the services of SDI 206. TAS 204 may perform business process orchestration, which will execute the relevant business process to complete the provisioning aspect of the order. In one embodiment, TAS 204 may use a BPEL (Business Process Execution Language) Process Manager to orchestrate the steps involved in the provisioning and handle the lifecycle operations.

(4) In one embodiment, to provision a database service, SDI 206 may call PLSQL APIs in the CLOUD_UI to associate a schema for the requesting customer.

(5) After successful association of a schema to the customer, SDI signals TAS and TAS send a notification to the customer that the database service is now available for use by the customer.

(6) The customer may log into cloud infrastructure system 100 (e.g., using an URL such as cloud.oracle.com) and activate the service.

In some embodiments, a customer may also be allowed to subscribe to a service on a trial basis. For example, such a trial order may be received via cloud UI 212 (e.g., using cloud.oracle.com).

In certain embodiments, cloud infrastructure system 100 enables underlying hardware and service instances to be shared between customers or tenants. For example, the database service may be provisioned as shown in FIG. 7E in one embodiment. FIG. 7E depicts multiple Exadata compute nodes 730 and 732, each providing a database instance provisioned for the database service. For example, compute node 730 provides a database instance 734 for a database service. Each Exadata compute node may have multiple database instances.

22

In certain embodiments, each database instance can comprise multiple schemas and the schemas may be associated with different customers or tenants. For example, in FIG. 7E, database instance 734 provides two schemas 736 and 738, each with its own tables. Schema 736 may be associated with a first customer or tenant subscribing to a database service and schema 738 may be associated with a second customer or tenant subscribing to the database service. Each tenant gets a completely isolated schema. Each schema acts like a container that can manage database objects including tables, views, stored procedures, triggers, etc. for the associated tenant. Each schema may have one dedicated tablespace, with each tablespace having one data file.

In this manner, a single database instance can provide database services to multiple tenants. This not only enables sharing of underlying hardware resources but also enables sharing of service instance between tenants.

In certain embodiments, such a multi-tenancy system is facilitated by IDM 200, which beneficially enables multiple separate customers, each having their own separate identity domains, to use hardware and software that is shared in the cloud. Consequently, there is no need for each customer to have its own dedicated hardware or software resources, and in some cases resources that are not being used by some customers at a particular moment can be used by other customers, thereby preventing those resources from being wasted. For example, as depicted in FIG. 7E, a database instance can service multiple customers each with their respective identity domains. Although each such database service instance can be a separate abstraction or view of a single physical multi-tenant database system that is shared among the many separate identity domains, each such database service instance can have a separate and potentially different schema than each other database service instance has. Thus, the multi-tenant database system can store mappings between customer-specified database schemas and the identity domains to which those database schemas pertain. The multi-tenant database system can cause the database service instance for a particular identity domain to use the schema that is mapped to that particular identity domain.

The multi-tenancy can also be extended to other services such as the Java Service. For example, multiple customers can have a JAVA service instance placed within their respective identity domains. Each such identity domain can have a JAVA virtual machine, which can be viewed as being a virtual “slice” of hardware. In one embodiment, a job-monitoring service (e.g., Hudson) can be combined with a JAVA enterprise edition platform (e.g., Oracle WebLogic) in the cloud to enable each separate identity domain to have its own separate virtual “slice” of the JAVA enterprise edition platform. Such a job-monitoring service can, for example, monitor the execution of repeated jobs, such as building a software project or jobs run by an operating system’s time-based job scheduler. Such repeated jobs can include the continuous building and/or testing of software projects. Additionally or alternatively, such repeated jobs can include the monitoring of executions of operating system-run jobs that are executed on machines that are remote from the machine on which the job-monitoring service executes.

When a subscription order from a customer is received, cloud infrastructure system 100 has to perform several processing steps before the services requested by the order are usable by the customer. For example, these processing steps may involve verifying the order that may in turn require getting additional information from the customer, provisioning resources for providing one or more requested services, creating identity domains to ensure security for the customer

data, and the like. Many of these processing steps may take some time to be performed. However, the customer typically wants to start using the ordered services as soon as possible. In certain embodiments, techniques for automating the provisioning, managing and tracking of services provided by cloud infrastructure system **100** include providing the customer with the ability to gain access to services requested in the subscription order upon placing the subscription order and without the customer having to wait until all the steps involved in processing the subscription order are complete.

In one embodiment, the overall steps that are performed after a subscription order is received are categorized into two categories:

- (1) "primary steps" that include the minimal one or more steps that need to be performed before the ordered services can be provided and made available for the customer; and
- (2) "secondary steps" that include steps that are performed in response to receiving a subscription order but which are not essential for making the services available to the customer initially. Accordingly, from the overall steps that are performed in response to a subscription order, any step that is not categorized as a primary step is categorized as a secondary step. A primary step is not dependent upon a secondary step.

In certain embodiments, a primary order workflow is defined for a subscription order that only comprises the primary steps. One or more secondary order workflows may be defined that comprise the secondary steps. Upon receiving a subscription order, a set of one or more workflows related to processing to be performed for the order are identified. The set of workflows includes a primary order workflow and one or more secondary order workflows related to processing to be performed for the subscription order. In one embodiment, upon execution of the primary steps in the primary order workflow, the customer is provided access to the services requested in the subscription order. The customer does not have to wait until processing of all the secondary steps are completed before the customer can access the ordered services. The secondary steps may be executed concurrently with the primary steps, where possible, or may be executed after the primary steps have been executed, to complete processing of the subscription order.

In certain embodiments, the primary steps for a subscription order depend upon the contents of the subscription order. For example, the primary steps for an order may depend upon the services that are ordered or even the level of service ordered.

In a typical example, the primary steps involved in processing a subscription order may include at least provisioning the allocation of the physical resources and creating an identity domain, if necessary, along with customer identities so that the customers can gain access to the service. Other back office functions related to the subscription order such as accounting and support that are not necessary for a customer to start using the service may be completed after the customer gains access to the service and are categorized as secondary steps. For example, some of the processing performed by order management module **214** such as creating a customer record and performing accounting functions related to the subscription order may be categorized as secondary steps. In one embodiment, the secondary step of creating customer records may be performed by order management module **214** concurrently with the primary step of provisioning resources for the subscription that is performed by SDI module **206**.

FIG. **8** is a high level block diagram of a system for processing a customer's subscription order, in accordance with one embodiment of the invention. The embodiment depicted in FIG. **8** comprises an order workflow identification module

324, which is part of TAS module **204**. As illustrated in FIG. **8**, in one embodiment, order workflow identification module **322** includes a primary order workflow identification module **802**, a secondary order workflow identification module **804** and an order workflow processing module **806**. These modules may be implemented in hardware, or software, or combinations thereof. The modules in order workflow identification module **322** depicted in FIG. **8** are meant for illustrative purposes only and are not intended to limit the scope of embodiments of the present invention. For example, alternative embodiments of the present invention may include additional modules in order workflow identification module **324**.

Upon receiving a customer's subscription order from order processing module **310** as discussed in FIG. **3B**, in one embodiment, primary order workflow identification module **802** analyzes the subscription order to identify a primary order workflow related to the customer's subscription order. The primary order workflow includes one or more primary steps related to processing the subscription order. For example, primary order workflow identification module **802** may identify a primary order flowchart comprising steps **P1-P8** discussed below:

P1: Receiving a customer's subscription order via store UI **210** or cloud UI **212**.

P2: Creating a customer record associated with the subscription order.

P3: Creating a logical subscription footprint of the customer's subscription order. In one example, the logical subscription footprint may include creating a set of records associated with the customer's subscription order such as the customer record, a customer account information record, a service configuration record and so on.

P4: Creating an identity domain administrator or a system administrator associated with the customer's subscription.

P5: Creating an account administrator associated with the customer's subscription.

P6: Creating a physical subscription footprint associated with the customer's subscription. This involves allocating a minimum set of resources requested by the customer so that the customer can gain access to the services in the subscription order.

P7: Enabling monitoring of the physical subscription footprint.

P8: Sending a notification to the customer that the customer can start accessing the services in the subscription order.

It is to be appreciated that the example of primary steps described above is not intended to be limiting. Primary order workflow identification module **802** then inputs the primary order workflow to order workflow processing module **806** for execution. Order workflow processing module **806** then causes the primary order workflow to be executed. The primary order workflow can be executed independent of the secondary order workflows.

Executing the primary order workflow may possibly involve additional components of cloud infrastructure system **100**. For example, for the example provided above, primary step **P1** may be executed via the front-end interfaces, store UI **210** or cloud UI **212**, primary steps **P2** and **P3** may be executed by order management module **214**, primary steps **P4** and **P5** may be executed by TAS module **204**, primary step **P6** may be executed by TAS module **204** and SDI module **206**, primary step **P7** may be executed by EM module **208** and primary step **P8** may be executed by services module **202**. Upon execution of the steps in the primary order workflow, the order workflow processing module **806** notifies service component **202** that the customer can start utilizing the ser-

25

vices in the subscription order. In one embodiment, a URL that can be used by the customer to access the ordered services may be provided to the customer as part of the notification.

Secondary order workflow identification module **804** is configured to analyze the subscription order and identify one or more secondary order workflows related to the subscription order. Each secondary order workflow may include one or more secondary steps related to processing the subscription order. For example, in one embodiment, secondary order workflow identification module **804** may identify a secondary order workflow comprising steps, S1-S12 discussed below:

S1: Creating the customer's billing schedule in order management module **214**.

S2: Creating the customer's contract information in the contract management module in order management module **214**.

S3: Creating the entitlement footprint in the install base module of order management module **214**. As used herein, the entitlement footprint includes information about the amount of resources that a customer is entitled to. The entitlement data may be determined based on customer information and a set of centralized access control policies. In one embodiment, the resources that a customer is entitled to may be automatically provisioned to the customer when the customer places a subscription order without the involvement of a service administrator.

S4: Creating the customer's invoice in order management module **214**.

S5: Sending the entitlement footprint to the support system.

S6: Sending subscription information (including buyer, identity domain administrator and service administrator information) to the support system.

S7: Creating a subscription record in the support system.

S8: Enabling the buyer to access the support system via support UI **216**.

S9: Enabling the identity domain administrator to access the support system via support UI **216**.

S10: Enabling the service administrator to access the support system via support UI **216**.

S11: Processing additional physical subscription footprint configuration steps that include, for example, additional index creation, additional virtual machine allocation, additional language pack installation, additional sample data creation etc.

S12: Creating a non-admin user.

It is to be appreciated that the secondary steps S1-S12 listed above are merely examples of secondary steps and are not intended to limit the scope of the present invention. Secondary order workflow identification module **804** is configured to input the one or more secondary order workflows to order workflow processing module **806**, which may then cause the secondary workflows to be executed. Executing the secondary order workflows may possibly involve additional components of cloud infrastructure system **100**.

As previously described, the execution of the primary order workflow is not dependent upon the execution of one or more secondary order workflows. In some situations, one or more secondary steps of the secondary order workflows may be executed after the primary order workflow execution has completed. In some other situations, one or more secondary steps in the secondary order workflows may be executed in parallel or concurrently with some of the primary steps in the primary order workflow. For example, order management module **214** may perform the secondary step of creating the customer's subscription records concurrently with SDI mod-

26

ule **206** performing the primary step of creating provisioning resources for the subscription. Further, the secondary order workflows may be executed in series, or where possible, one or more may be executed in parallel. Accordingly, where possible, two or more secondary steps may be performed concurrently.

FIG. **9A** depicts a simplified flowchart depicting processing that may be performed by order workflow identification module **324** in TAS module **206** to process a subscription order using primary and secondary order workflows, in accordance with an embodiment of the present invention. The processing **900** depicted in FIG. **9A** may be implemented in software (e.g., code, instructions, program) executed by one or more processors, hardware, or combinations thereof. The software may be stored in memory (e.g., on a memory device, on a non-transitory computer-readable storage medium). The particular series of processing steps depicted in FIG. **9A** is not intended to be limiting. Other sequences of steps may also be performed according to alternative embodiments. For example, alternative embodiments of the present invention may perform the steps outlined above in a different order. Moreover, the individual steps illustrated in FIG. **9A** may include multiple sub-steps that may be performed in various sequences as appropriate to the individual step. Furthermore, additional steps may be added or removed depending on the particular applications. One of ordinary skill in the art would recognize many variations, modifications, and alternatives. In one embodiment, the processing depicted in FIG. **9A** may be performed by one or more modules in order workflow identification module **324** discussed in detail in FIG. **8**.

At **902**, subscription order information related to a subscription order ordering a service from a set of services provided by cloud infrastructure system **100** is stored. In one embodiment, order database **224** stores the subscription order information. Subscription order information may include information about the order such as a service type, a service level, a customer level, the type of resources, the amount of the resources to be assigned to the service type and a time period during which the service is desired.

At **904**, a primary order workflow for processing the subscription order is identified based on the subscription order information. The primary order workflow includes one or more steps to be performed prior to enabling use of the ordered services in the subscription order. In one embodiment, and as discussed in FIG. **8**, the primary order workflow includes one or more primary steps related to processing the subscription order, which may include for example, creating a logical subscription footprint, a physical subscription footprint and an account administrator related to the subscription order.

At **906**, a secondary order workflow for processing the subscription order is identified based on the subscription order information. The secondary order workflow includes one or more steps to be performed for completing processing the subscription order. In one embodiment, and as discussed in FIG. **8**, the secondary order workflow includes one or more secondary steps related to processing the subscription order, which may include for example creating an entitlement footprint and accounting records for the customer and configuring additional resources for the customer based on the physical subscription footprint related to the subscription order.

At **908**, access to the ordered services in the subscription order is enabled after completion of execution of the primary order workflow. In one embodiment, access to the ordered services is enabled before completion of execution of one or more steps in the secondary order workflow. Accordingly, a customer is able to start using the ordered services even

though one or more of the secondary steps needed to complete processing the subscription order have all not been completed. In one embodiment, one or more of the steps in the secondary order workflow may be executed concurrently with one or more of the steps in the primary order workflow to complete the processing of the subscription order. In another embodiment, one or more of the steps in the secondary order workflow may be executed after one or more of the steps in the primary order workflow to complete the processing of the subscription order.

At 909, upon completion of execution of the steps in the primary order workflow, the customer is notified so that the customer can start utilizing the ordered services in the subscription order.

FIG. 9B discusses an example of how one or more secondary steps in a secondary order workflow may be executed in relationship with one or more primary steps in a primary order workflow to process a customer's subscription order according to an embodiment of the present invention. Referring to FIG. 9B, in one embodiment, the primary order workflow comprises primary steps P1-P8 (corresponding to the primary order workflow example described above) that are executed in order as each one has a dependency on the preceding primary step. The secondary order workflow comprises secondary steps S1-S12 (corresponding to the secondary order workflow example described above).

As can be seen from FIG. 9B, in one embodiment, secondary steps S1, S2 and S3 of creating the customer's billing schedule, creating contract information and creating entitlement footprint information may be executed in order as each one has a dependency on the preceding secondary step. In one example, and as shown in FIG. 9B, secondary step S1 may execute in parallel with primary step P1 followed by the execution of secondary steps S2 and S3.

In certain embodiments, the execution of primary steps P1-P5 need to be complete before the secondary step S6 of sending the subscription information to the support system can be executed. However, the secondary step S6 can be executed in parallel with either primary step P6, P7 or P8 of creating a physical subscription footprint, monitoring the physical subscription footprint, and sending a notification to the customer, respectively. In addition, secondary steps S5 and S6 of sending the entitlement footprint and the subscription information can be executed in parallel.

In one embodiment, secondary steps S5, S6, S7 are completed before the secondary steps S8, S9, S10 of enabling the buyer, identity domain administrator and service administrator to access the support system, can be executed. However, the secondary steps S8, S9, S10 can be executed in parallel.

In one embodiment, the customer does not get billed before the customer accesses the subscription. So, the invoice creation step (S4) has a dependency on the physical subscription creation step (P6). In addition, the primary step P8 of notifying the customer about completion of the processing of the subscription order is completed before the secondary step S4 of creating an invoice can be executed. However, the secondary step S4 can be executed before or concurrently with the secondary steps S11 and S12 of secondary physical configuration and non-admin user creation, respectively. In one embodiment, the primary order workflow and the secondary order workflow may be modeled as a directed graph in which the nodes of the graph represent the primary steps and the secondary steps and the edges of the graph represent the dependencies between these steps. In one implementation, all the ancestor nodes of any primary step node are primary step nodes because all the ancestor steps are completed before a descendant step can be completed. On the other hand, the

descendant nodes of a primary step node can be either primary or secondary step nodes.

FIG. 9C is a high level flowchart 910 illustrating a method for executing steps for processing a subscription order using a primary order workflow in accordance with one embodiment of the present invention. Referring to FIG. 9A, the method 910 includes receiving a customer's subscription order (912). A series of determinations are then made: has a customer record for the subscription order been generated (914), has the logical subscription footprint for the subscription order been generated (916), has a system administrator for the subscription order been created (918), has a service administrator for the subscription order been created (920), has the physical subscription footprint for the subscription order been generated (922) and has the monitoring for the subscription order been enabled (924). If any of the conditions in any of the steps 914-924 are not met, then the particular step associated with providing the customer access to subscription order is submitted for execution to one or more components in cloud infrastructure system 100 (926). Once all the primary steps have been executed (928), then the customer's access to the subscription order is provided and the customer is notified (930). If any of the conditions in any of the steps 914-924 are not met, then the customer's access to the subscription order is declined (932).

It should be appreciated that the specific steps illustrated in FIG. 9C provide a particular method of processing a primary order workflow associated with a customer's subscription order according to an embodiment of the present invention. Other sequences of steps may also be performed between steps 912 and 932 in other embodiments. For example, alternative embodiments of the present invention may perform the steps outlined in FIG. 9C in a different order. Moreover, the individual steps illustrated in FIG. 9C may include multiple sub-steps that may be performed in various sequences as appropriate to the individual step. One of ordinary skill in the art would recognize many variations, modifications, and alternatives.

FIG. 10 is a simplified block diagram of a computing system 1000 that may be used in accordance with embodiments of the present invention. For example, cloud infrastructure system 100 may comprise one or more computing devices. System 1000 depicted in FIG. 10 may be an example of one such computing device. Computer system 1000 is shown comprising hardware elements that may be electrically coupled via a bus 1024. The hardware elements may include one or more central processing units (CPUs) 1002, one or more input devices 1004 (e.g., a mouse, a keyboard, etc.), and one or more output devices 1006 (e.g., a display device, a printer, etc.). The CPUs may include single or multicore CPUs. Computer system 1000 may also include one or more storage devices 1008. By way of example, the storage device(s) 1008 may include devices such as disk drives, optical storage devices, and solid-state storage devices such as a random access memory (RAM) and/or a read-only memory (ROM), which can be programmable, flash-updateable and/or the like.

Computer system 1000 may additionally include a computer-readable storage media reader 1012, a communications subsystem 1014 (e.g., a modem, a network card (wireless or wired), an infra-red communication device, etc.), and working memory 1018, which may include RAM and ROM devices as described above. In some embodiments, computer system 1000 may also include a processing acceleration unit 1016, which can include a digital signal processor (DSP), a special-purpose processor, and/or the like.

Computer-readable storage media reader **1012** can further be connected to a computer-readable storage medium **1010**, together (and, optionally, in combination with storage device(s) **1008**) comprehensively representing remote, local, fixed, and/or removable storage devices plus storage media for temporarily and/or more permanently containing computer-readable information. Communications system **1014** may permit data to be exchanged with network **1024** and/or any other computer described above with respect to system environment **1000**.

Computer system **1000** may also comprise software elements, shown as being currently located within working memory **1018**, including an operating system **1020** and/or other code **1022**, such as an application program (which may be a client application, Web browser, mid-tier application, RDBMS, etc.). In an exemplary embodiment, working memory **1018** may include executable code and associated data structures such as memory structures used for processing authorization requests described above. It should be appreciated that alternative embodiments of computer system **1000** may have numerous variations from that described above. For example, customized hardware might also be used and/or particular elements might be implemented in hardware, software (including portable software, such as applets), or both. Further, connection to other computing devices such as network input/output devices may be employed.

Storage media and computer readable media for containing code, or portions of code, can include any appropriate media known or used in the art, including storage media and communication media, such as but not limited to volatile and non-volatile, removable and non-removable media implemented in any method or technology for storage of information such as computer readable instructions, data structures, program modules, or other data. Examples of storage and computer-readable media include RAM, ROM, EEPROM, flash memory or other memory technology, CD-ROM, digital versatile disk (DVD) or other optical storage, magnetic cassettes, magnetic tape, magnetic disk storage or other magnetic storage devices, or any other memory medium which can be used to store the desired information and which can be read by a computer. Storage media and computer readable media may include non-transitory memory devices.

Although specific embodiments of the invention have been described, various modifications, alterations, alternative constructions, and equivalents are also encompassed within the scope of the invention. Embodiments of the present invention are not restricted to operation within certain specific data processing environments, but are free to operate within a plurality of data processing environments. Additionally, although embodiments of the present invention have been described using a particular series of transactions and steps, it should be apparent to those skilled in the art that the scope of the present invention is not limited to the described series of transactions and steps.

Further, while embodiments of the present invention have been described using a particular combination of hardware and software, it should be recognized that other combinations of hardware and software are also within the scope of the present invention. Embodiments of the present invention may be implemented only in hardware, or only in software, or using combinations thereof.

The specification and drawings are, accordingly, to be regarded in an illustrative rather than a restrictive sense. It will, however, be evident that additions, subtractions, deletions, and other modifications and changes may be made thereunto without departing from the broader spirit and scope as set forth in the claims.

What is claimed is:

1. A method comprising:

receiving, by a computing infrastructure system, a subscription order for a customer, the subscription order comprising subscription order information identifying a first service subscribed to by the customer from one or more services provided by the computing infrastructure system, the computing infrastructure system comprising one or more computing devices;

identifying, by a computing device from the one or more computing devices, based upon the subscription order information, a primary order workflow for processing the subscription order, the primary order workflow comprising one or more primary steps to be performed for processing the subscription order;

identifying, by the computing device, based upon the subscription order information, a secondary order workflow for processing the subscription order, the secondary order workflow comprising one or more secondary steps to be performed for completing processing of the subscription order;

executing the one or more primary steps in the primary order workflow;

enabling, by the computing device, access to the first service after completion of execution of the one or more primary steps in the primary order workflow; and

performing the one or more secondary steps, the one or more secondary steps comprising configuring additional resources for the customer.

2. The method of claim 1 comprising executing at least one or more of the secondary steps in the secondary order workflow concurrently with one or more of the primary steps in the primary order workflow to complete the processing of the subscription order.

3. The method of claim 2 wherein the one or more primary steps in the primary order workflow include at least one or more of creating a logical subscription footprint, a physical subscription footprint and an account administrator related to the subscription order.

4. The method of claim 3 wherein the one or more secondary steps in the secondary order workflow include at least one or more of creating an entitlement footprint and accounting records for the customer and configuring the additional resources for the customer based at least in part on the physical subscription footprint related to the subscription order.

5. The method of claim 2 wherein executing at least one or more of the secondary steps in the secondary order workflow concurrently with one or more of the primary steps in the primary order workflow comprises creating accounting records for the customer concurrently with provisioning resources for the subscription.

6. The method of claim 1 wherein enabling access to the ordered service comprising notifying the customer to utilize the ordered services in the subscription order upon completion of execution of the primary steps in the primary order workflow.

7. The method of claim 1 comprising executing at least one or more of the secondary steps in the secondary order workflow after one or more of the primary steps in the primary order workflow to complete the processing of the subscription order.

8. A system comprising:

one or more computing devices configured to provide one or more

a memory configured to store subscription order information related to a subscription order ordering a first service from the set of services; and

31

wherein a computing device from the one or more computing devices is configurable to:

identify, based upon the subscription order information, a primary order workflow for processing the subscription order, the primary order workflow comprising one or more primary steps to be performed for processing the subscription order prior to enabling use of the; and
 identify, based upon the subscription order information, a secondary order workflow for processing the subscription order, the secondary order workflow comprising one or more secondary steps to be performed for completing processing of the subscription order;
 execute the one or more primary steps in the primary order workflow;
 enable access to the first service after completion of execution of the one or more primary steps in the primary order workflow; and
 performing the one or more secondary steps, the one or more secondary steps comprising configuring additional resources for the customer.

9. The system of claim **8** wherein the computing device is configured to execute at least one or more of the secondary steps in the secondary order workflow concurrently with one or more of the primary steps in the primary order workflow to complete the processing of the subscription order.

10. The system of claim **8** wherein the computing device is configured to execute at least one or more of the secondary steps in the secondary order workflow after one or more of the primary steps in the primary order workflow to complete the processing of the subscription order.

11. The system of claim **10** wherein the one or more primary steps in the primary order workflow include at least one or more of creating a logical subscription footprint, a physical subscription footprint and an account administrator related to the subscription order.

12. The system of claim **10** wherein the one or more secondary steps in the secondary order workflow include at least one or more of creating an entitlement footprint and accounting records for the customer and configuring the additional resources for the customer based on the physical subscription footprint related to the subscription order.

13. The system of claim **10** wherein the computing device is configured to create accounting records for the customer concurrently with provisioning resources for the subscription order.

14. The system of claim **8** wherein the computing device is configured to notify the customer to utilize the ordered services in the subscription order upon completion of execution of the primary steps in the primary order workflow.

15. A computer-readable memory storing a plurality of instructions executable by one or more processors, the plurality of instructions comprising:

instructions that cause at least one processor from the one or more processors to receive a subscription order for a customer, the subscription order comprising subscription order information identifying a first service subscribed to by the customer from one or more services provided by a computing infrastructure system;

32

instructions that cause at least one processor from the one or more processors to identify based upon the subscription order information, a primary order workflow for processing the subscription order, the primary order workflow comprising one or more primary steps to be performed for processing the subscription order;

instructions that cause at least one processor from the one or more processors to identify based upon the subscription order information, a secondary order workflow for processing the subscription order, the secondary order workflow comprising one or more secondary steps to be performed for completing processing of the subscription order;

instructions that cause at least one processor from the one or more processors to execute the one or more primary steps in the primary order workflow;

instructions that cause at least one processor from the one or more processors to enable access to the first service after completion of execution of the one or more primary steps in the primary order workflow; and

instructions that cause at least one processor from the one or more processors to perform the one or more secondary steps, the one or more secondary steps comprising configuring additional resources for the customer.

16. The computer-readable memory of claim **15** wherein the instructions that cause at least one processor from the one or more processors to enable access to the ordered services comprise instructions to execute at least one or more of the secondary steps in the secondary order workflow concurrently with one or more of the primary steps in the primary order workflow to complete the processing of the subscription order.

17. The computer-readable memory of claim **15** wherein the instructions that cause at least one processor from the one or more processors to enable access to the first service comprise instructions to execute at least one or more of the secondary steps in the secondary order workflow after one or more of the primary steps in the primary order workflow to complete the processing of the subscription order.

18. The computer-readable memory of claim **15** wherein the one or more primary steps in the primary order workflow include at least one or more of creating a logical subscription footprint, a physical subscription footprint and an account administrator related to the subscription order.

19. The computer-readable memory of claim **15** wherein the one or more secondary steps in the secondary order workflow include at least one or more of creating an entitlement footprint and accounting records for the customer and configuring the additional resources for the customer based on the physical subscription footprint related to the subscription order.

20. The computer-readable memory of claim **15** wherein the instructions that cause at least one processor from the one or more processors to enable access to the first service comprise instructions to notify the customer to utilize the first service in the subscription order upon completion of execution of the primary steps in the primary order workflow.

UNITED STATES PATENT AND TRADEMARK OFFICE
CERTIFICATE OF CORRECTION

PATENT NO. : 9,397,884 B2
APPLICATION NO. : 13/841243
DATED : July 19, 2016
INVENTOR(S) : Chatterjee et al.

Page 1 of 1

It is certified that error appears in the above-identified patent and that said Letters Patent is hereby corrected as shown below:

On the Title Page

Page 4, item [56], Column 2, Line 34, delete “Idapsearch,” and insert -- ldapsearch, --, therefor.

In the Claims

Column 30, Line 64, Claim 8, after “more” insert -- services; --.

Column 31, Line 7, Claim 8, after “order” delete “prior to enabling use of the”.

Signed and Sealed this
