(57) **ABSTRACT**

A semiconductor device is provided as a back-illuminated solid-state imaging device. The device is manufactured by bonding a first semiconductor wafer with a pixel array in a half-finished product state and a second semiconductor wafer with a logic circuit in a half-finished product state together, making the first semiconductor wafer into a thin film, electrically connecting the pixel array and the logic circuit, making the pixel array and the logic circuit into a finished product state, and dividing the first semiconductor wafer and the second semiconductor being bonded together into microchips.

SEMICONDUCTOR DEVICE AND METHOD OF MANUFACTURING THE SAME, AND ELECTRONIC APPARATUS

BACKGROUND OF THE INVENTION

1. Field of the Invention

The present invention relates to a semiconductor device, such as a solid-state imaging device, and a method of manufacturing such a semiconductor device. The present invention also relates to an electronic apparatus, such as a camera, equipped with the semiconductor device.

2. Description of the Related Art

Solid-state imaging devices, which have been commonly used, include amplification-type solid-state imaging devices as typified by MOS image sensors such as complementary metal oxide semiconductors (CMOSs) and charge-transfer solid-state imaging devices as typified by charge coupled device (CCD) image sensors. These solid-state imaging devices have been widely used for digital still cameras, digital video cameras, and so on. Furthermore, in recent years, MOS image sensors have been used for most of solid-state imaging devices mounted on mobile devices such as camera cell-phones and PDAs (Personal Digital Assistants) because of their low power voltages, low consumption powers, and so on.

The MOS solid-state imaging device includes a pixel array (pixel region) where a plurality of unit pixels are arranged in a two-dimensional array, and a peripheral circuit region. The unit pixel is formed of a photodiode and a plurality of pixel transistors, serving as a photoelectric conversion part. The pixel transistors may be three MOS transistors: a transfer transistor, a reset transistor, and an amplification transistor, or may be four in which a selection transistor is further included.

Some of the MOS solid-state imaging devices are those in which a semiconductor chip with a pixel region on which a plurality of pixel is arranged is electrically connected to a semiconductor chip in which a logic circuit for signal processing is formed to form a single device. Various kinds of such a device have been proposed. For example, Japanese Unexamined Patent Application Publication No. 2006-49361 discloses a semiconductor module where a back-illuminated image sensor chip having a micro-pad for each pixel cell and a signal processing chip, on which a signal processing circuit is formed, having a micro-pad are connected to each other via a micro-bump. Japanese Unexamined Patent Application Publication No. 2007-13089 discloses a device on which a sensor chip and a signal processing chip are mounted on an interposer (intermediate substrate). The sensor chip is a back-illuminated MOS solid-state imaging device with an imaging pixel section and the signal processing chip is provided with a peripheral circuit performing signal processing. In Japanese Unexamined Patent Application Publication No. 2008-130603, an imaging device includes an image sensor chip, a thin-layer circuit board, and a logic circuit chip for signal processing. In addition, it also discloses the configuration of the device in which the thin-layer circuit board and the logic circuit chip are electrically connected to each other. In this case, the thin-layer circuit board is electrically connected from the backside of the image sensor chip through a through-hole-via.

In addition, Japanese Patent No. 4000507 discloses a solid-state imaging device provided with a penetration electrode on a solid-state imaging element supported on a transparent substrate, where the solid-state imaging element

is electrically connected to a flexible circuit substrate. Furthermore, Japanese Unexamined Patent Application Publication No. 2003-31785 discloses a back-illuminated solid-state imaging device provided with an electrode passing through a supporting substrate.

As described in Japanese Unexamined Patent Application Publication Nos. 2006-49361, 2007-13089, and 2008-130603, various technologies for combining an image sensor chip with different circuit chips such as logic circuit have been proposed. In these technologies, any of functional chips is almost completely built up in advance and then mounted on a substrate while being allowed to make a connection between the chips by the formation of a connection through hole.

SUMMARY OF THE INVENTION

As is evident from any of the above solid-state imaging devices, there is an idea of constructing a semiconductor device by making a connection between different microchips using a connection conductor passing through a substrate. However, a connection hole has to be formed deeply in a substrate while being insulated. Thus, it is practically difficult from the viewpoints of the processing of a connection hole and the cost effectiveness of a process for embedding a connection conductor.

On the other hand, the formation of a contact hole with a small diameter of about 1 micrometer uses the thinning of an upper chip to the minimum. In this case, however, some complicated steps, such as one for bonding the upper chip on a supporting substrate, may be desired, which causes an increase in cost. In order to embed the connection conductor in the connection hole with a high aspect ratio, the connection conductor materials are limited because it is necessary to use a CVD film with good coatability, such as tungsten (W), as a connection conductor.

In order to have economical efficiency simply applicable by mass production, it is desirable to choose such art that the aspect ratio of this connecting hole is lowered dramatically so as to form the hole easily and the hole is processed within a related-art wafer manufacturing process without using special connecting hole processing.

Furthermore, it is desirable to provide the solid-state imaging device with a high performance by designing both an imaging region and a logic circuit for signal processing to sufficiently exert their respective performances.

In addition to the solid-state imaging device, it is also desirable to provide any of other semiconductor devices having semiconductor integrated circuits with high performance by designing the circuits to sufficiently exert their respective performances.

The present invention has been made in consideration of the aforementioned desires and intends to provide a solid-state imaging device that allows its circuits to sufficiently exert their respective capabilities to attain mass productivity and cost reduction.

Also, the present invention intends to provide an electronic apparatus, such as a camera, equipped with the above solid-state imaging device.

According to an embodiment of the present invention, a semiconductor device is a back-illuminated solid-state imaging device that includes microchips prepared by bonding a first semiconductor wafer having a pixel array in a half-finished product state (hereinafter, also referred to as a half-finished pixel array) and a second semiconductor wafer having a logic circuit in a half-finished product state (hereinafter, also referred to as a half-finished logic circuit)

3

together and then completing the circuits to make them into microchips. The bonding may include bonding the semiconductor wafers together, thinning the first semiconductor wafer, and making an electric connection between the pixel array and the logic circuit.

In the semiconductor device according to the embodiment of the present invention, a pixel array is formed on a microchip part made of a first semiconductor wafer and a logic circuit is formed on a microchip part of a second semiconductor wafer. Thus, the pixel array and the logic circuit are formed under optimal conditions. Under the optimal process technology, the pixel array and the logic circuit that exert sufficient performance capabilities can be formed.

The second semiconductor wafer with the half-finished logic circuit can also serve as a substrate supporting the first semiconductor wafer to be thinned. Subsequently, the first semiconductor wafer with the half-finished pixel array and the second semiconductor wafer with the half-finished logic circuit are bonded together. Finally, the pixel array in a finished product state and the logic circuit in a finished product state are formed. Therefore, the back-illuminated solid-state imaging device suitable for mass production and cost reduction can be obtained.

A method of manufacturing a semiconductor device according to an embodiment of the present invention prepares a first semiconductor wafer with a half-finished pixel array and a second semiconductor wafer with a half-finished logic circuit. The method includes steps of bonding the first semiconductor wafer and the second semiconductor wafer together, thinning the first semiconductor wafer, and electrically connecting the pixel array and the logic circuit together. The method further includes steps of completing the first semiconductor wafer and the second semiconductor wafer which are bonded together and cutting them into pieces for the respective microchips. Consequently, the back-illuminated solid-state imaging device can be produced.

In the method of manufacturing the semiconductor device according to the embodiment of the present invention, the pixel array is formed on the microchip part of the first semiconductor wafer and the logic circuit is formed on the microchip part of the second semiconductor wafer. Both the pixel array and the logic circuit can be formed under optimum conditions. In other words, under the optimal process technology, the pixel array and the logic circuit that exert sufficient performance capabilities can be formed. In addition, the second semiconductor wafer with the half-finished logic circuit can also serve as a substrate supporting the first semiconductor wafer to be thinned. Subsequently, the first semiconductor wafer with the half-finished pixel array and the second semiconductor wafer with the half-finished logic circuit are bonded together, and then subjected to the thinning and the electric connection, followed by completing the wafers and dividing them into the respective microchips. Consequently, it becomes possible to mass-produce the back-illuminated solid-state imaging device. Thus, the solid-state imaging device can be produced at low cost.

An electronic apparatus according to an embodiment of the present invention includes a solid-state imaging device, an optical system that introduces incident light into a photodiode in the solid-state imaging device, and a signal-processing circuit that processes an output signal from the solid-state imaging device. In the electronic apparatus, the solid-state imaging device is a back-illuminated solid-state imaging device that includes microchips prepared by bond-

4

ing a first semiconductor wafer having a half-finished pixel array and a second semiconductor wafer having a half-finished logic circuit together and then completing the circuits to make them into microchips. The bonding may include bonding the semiconductor wafers together, thinning the first semiconductor wafer, and making an electric connection between the pixel array and the logic circuit. As the electronic apparatus of the present invention includes the solid-state imaging device of the embodiment of the present invention, the pixel array and the logic circuit that exert sufficient performance capabilities for the solid-state imaging device can be formed. In addition, the solid-state imaging device can be produced at low cost. Thus, the electronic apparatus can be produced at low cost.

According to an embodiment of the present invention, a semiconductor device includes microchips prepared by bonding a first semiconductor wafer having a half-finished first semiconductor integrated circuit and a second semiconductor wafer having a half-finished second semiconductor integrated circuit together and then completing the circuits to make them into microchips. The bonding may include bonding the semiconductor wafers together, thinning the first semiconductor wafer, and making an electric connection between the first semiconductor integrated circuit and the second semiconductor integrated circuit.

In the semiconductor device according to the embodiment of the present invention, a first semiconductor integrated circuit is formed on a microchip part made of a first semiconductor wafer and a second semiconductor integrated circuit is formed on a microchip part of a second semiconductor wafer. Thus, the first semiconductor integrated circuit and the second semiconductor integrated circuit are formed under optimal conditions. Under the optimal process technology, the first semiconductor integrated circuit and the second semiconductor integrated circuit that exert sufficient performance capabilities can be formed.

The second semiconductor wafer with the second semiconductor integrated circuit can also serve as a substrate supporting the first semiconductor wafer to be thinned.

Subsequently, the first semiconductor wafer with the half-finished first semiconductor integrated circuit and the second semiconductor wafer with the half-finished second semiconductor integrated circuit are bonded together to finally complete the semiconductor integrated circuits. Therefore, the semiconductor device suitable for mass production and cost reduction can be obtained.

A method of manufacturing a semiconductor device according to an embodiment of the present invention prepares a first semiconductor wafer with a half-finished first semiconductor integrated circuit and a second semiconductor wafer with a half-finished second semiconductor integrated circuit. The method includes steps of bonding the first semiconductor wafer and the second semiconductor wafer together, thinning the first semiconductor wafer, and electrically connecting the first semiconductor integrated circuit and the second semiconductor integrated circuit together. The method further includes steps of completing the first semiconductor wafer and the second semiconductor wafer which are bonded together and cutting them into pieces for the respective microchips.

In the method of producing the semiconductor device according to the embodiment of the present invention, a first semiconductor integrated circuit is formed on a microchip part made of a first semiconductor wafer and a second semiconductor integrated circuit is formed on a microchip part of a second semiconductor wafer. Thus, the first semiconductor integrated circuit and the second semiconductor

5

integrated circuit are formed under optimal conditions. Under the optimal process technology, the first semiconductor integrated circuit and the second semiconductor integrated circuit that exert sufficient performance capabilities can be formed.

In addition, the second semiconductor wafer with the half-finished second semiconductor integrated circuit can also serve as a substrate supporting the first semiconductor to be thinned. Subsequently, the first semiconductor wafer with the half-finished first semiconductor integrated circuit and the second semiconductor wafer with the half-finished second semiconductor integrated circuit are bonded together, and then subjected to the thinning and the electric connection, followed by completing the wafers and dividing them into the respective microchips. Consequently, it becomes possible to mass-produce the semiconductor device. Thus, the semiconductor device can be produced at low cost.

In the semiconductor device according to any of the embodiments of the present invention, the pixel array and the logic circuit that exert their respective sufficient performance capabilities are formed in each microchip part. Thus, a high-performance semiconductor device, or a back-illuminated solid-state imaging device, can be provided. In addition, the high-performance back-illuminated solid-state imaging device with excellent mass productivity and cost effectiveness can be provided.

In the semiconductor device according to any of the embodiments of the present invention, furthermore, the first semiconductor integrated circuit and the second semiconductor integrated circuit that exert their respective sufficient performance capabilities are formed in each microchip part. Therefore, a high-performance semiconductor device can be provided. In addition, the high-performance semiconductor device with excellent mass productivity and cost effectiveness can be provided.

In the method of manufacturing the semiconductor device according to any of the embodiments of the present invention, under the optimal process technology, a high-performance semiconductor device, or a high-performance back-illuminated solid-state imaging device, provided with the pixel array and the logic circuit that exert sufficient performance capabilities can be manufactured. In addition, the high-performance back-illuminated solid-state imaging device with excellent mass productivity and cost effectiveness can be provided.

In the method of manufacturing the semiconductor device according to any of the embodiments of the present invention, under the optimal process technology, a high-performance semiconductor provided with the first semiconductor integrated circuit and the second semiconductor integrated circuit that exert sufficient performance capabilities can be manufactured. In addition, the high-performance semiconductor device with excellent mass productivity and cost effectiveness can be produced.

The electronic apparatus according to the embodiment of the present invention includes a high-performance solid-state imaging device with a lower production cost.

Therefore, an inexpensive and reliable electronic apparatus can be provided.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 29 is a schematic diagram illustrating the configuration of an electronic apparatus according to a sixth embodiment of the present invention.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

Hereinafter, the best mode for carrying out the present invention will be described as embodiments thereof. The embodiments will be described in the following order:

1. Example of the schematic configuration of MOS solid-state imaging device;
2. First embodiment (an example of the configuration of a solid-state imaging device and the method of manufacturing the solid-state imaging device);
3. Second embodiment (an example of the configuration of a solid-state imaging device);
4. Third embodiment (an example of the configuration of a solid-state imaging device);
5. Fourth embodiment (an example of the configuration of a solid-state imaging apparatus and the method of manufacturing the solid-state imaging device);
6. Fifth embodiment (an example of the configuration of a semiconductor device and the method of manufacturing the solid-state imaging device); and
7. Sixth embodiment (an example of an electronic apparatus).

1. Example of the Schematic Configuration of MOS Solid-State Imaging Device

FIG. 1 is a schematic diagram illustrating an exemplary configuration of a MOS solid-state imaging device, which can be applied to a semiconductor device of any embodiment of the present invention. The configuration of the MOS solid-state imaging device illustrated in FIG. 1 is also applied to a solid-state imaging device according to each embodiment of the present invention. As shown in FIG. 1, the solid-state imaging device 1 includes a semiconductor substrate 11; a pixel section (so-called pixel array) 3, where a plurality of pixels 2 with photoelectric conversion parts are regularly placed on the silicon substrate 11, and a peripheral circuit section. Each pixel (i.e., unit pixel) 2 includes a photoelectric conversion part such as a photodiode and a plurality of pixel transistors (so-called MOS transistors). The plurality of pixel transistors may include, for example, three transistors: a transfer transistor, a reset transistor, and an amplification transistor. Alternatively, the plurality of pixel transistors may further include a selection transistor, thus including four transistors. The equivalent circuits of the unit pixel is the same as one typically used, so that the details thereof will be omitted in the following description. The

pixel 2 may be one unit pixel. Alternatively, the pixel 2 may have a shared pixel structure. The shared pixel structure includes a plurality of photodiodes, a plurality of transfer transistors, one shared floating diffusion, and each of shared other pixel transistors. In other words, the shared pixel structure includes photodiodes and transfer transistors, which constitute the plurality of unit pixels, and each of other shared pixel transistors.

The peripheral circuit section includes a vertical drive circuit 4, a column signal processing circuit 5, a horizontal drive circuit 6, an output circuit 7, a control circuit 8, and so on.

The control circuit 8 receives an input clock and data for the instruction of an operation mode and so on and outputs information such as the internal information of the solid-state imaging device. In other words, the control circuit 8 generates signals, such as a clock signal and a control signal to be referenced for driving the vertical drive circuit 4, the column signal processing circuit 5, the horizontal drive circuit 6, and so on. Then, the control unit 8 inputs these signals to the vertical drive circuit 4, the column signal processing circuit 5, the horizontal drive circuit 6, and so on.

The vertical drive circuit 4 includes a shift register or the like and drives pixels on a line by selecting a pixel-driving line and supplying a pulse for driving pixels to a selected pixel line-at-a-time. In other words, the vertical drive circuit 4 sequentially performs selective scanning of pixels 2 of the pixel region 3 line-at-a-time in the vertical direction. Then, the vertical drive circuit 4 supplies a pixel signal to the column signal processing circuit 5. Here, the pixel signal is based on a signal electric charge generated according to the amount of light received on the photoelectric transducer (e.g., photodiode) of each pixel 2 through a vertical signal line 9.

In this embodiment, for example, the column signal processing circuit 5 may be provided for each column of the pixels 2 and carries out signal processing, such as noise removal, of a signal output from each of the pixels 2 on one line. In other words, the column signal processing circuit 5 performs CDS (correlated double sampling) for removal of a fixed pattern noise specific to the pixel 2 and signal processing such as signal amplification and AD (analogue-to-digital) conversion. The output stage of the column signal processing circuit 5 is connected to a horizontal selection switch (not shown) which is located between the output stage and a horizontal signal line 10.

The horizontal drive circuit 6, which is constructed of a shift register or the like, sequentially outputs horizontal scanning pulses, selecting the respective column signal processing circuits 5 in order to output pixel signals thereof to the horizontal signal line 10.

The output circuit 7 carries out signal processing of signals sequentially supplied from the respective column signal processing circuits 5 through the horizontal signal line 10 and then outputs the processed signals. Specifically, for example, the output circuit 7 may only perform buffering or may perform black level adjustment, column variation compensation, various digital signal processing, and so on. An input/output terminal 12 carries out an exchange of signals between the device and the outside.

FIGS. 2A to 2C are schematic diagrams illustrating a fundamental configuration of a MOS solid-state imaging device according to an embodiment of the present invention. First, a typical MOS solid-state imaging device 151 will be described with reference to FIG. 2A. The typical MOS solid-state imaging device 151 includes a pixel region 153, a control circuit 154, and a logic circuit 155 for signal

processing, which are mounted on a single semiconductor chip **152**. In general, an image sensor **156** includes the pixel region **153** and the control circuit **154**. As shown in FIG. 2B, on the other hand, a MOS solid-state imaging device **21** according to the embodiment of the present invention includes a pixel region **23** and a control circuit (control region) **124** mounted on a first semiconductor chip section **22** and a logic circuit **25** including a signal processing circuit for signal processing mounted on a second semiconductor chip section **26**. The first semiconductor chip section **22** and the second semiconductor chip section **26** are electrically connected to each other to form a single semiconductor chip to provide the MOS solid-state imaging device **21**. As shown in FIG. 2C, in a MOS solid-state imaging device **27** according to another embodiment of the present invention, a pixel region **23** is mounted on a first semiconductor chip section **22**. Also, a control circuit **24** and a logic circuit **25** including signal processing circuit are mounted on a second semiconductor chip section **26**. The first semiconductor chip section **22** and the second semiconductor chip section **26** are electrically connected to each other to form a single semiconductor chip to provide the MOS solid-state imaging device **27**.

The features of the MOS solid-state imaging devices according to the above embodiments are found in their manufacturing methods and their configurations based on such methods as described later.

2. First Embodiment

Example of Configuration of Solid-State Imaging Device and Example of Method of Manufacturing the Solid-State Imaging Device

Referring now to FIG. 3 and FIGS. 4 to 13, a semiconductor device (i.e., a MOS solid-state imaging device) and a method of manufacturing the solid-state imaging device will be described.

In the first embodiment, first, as shown in FIG. 4, a half-finished image sensor, or an pixel array (hereinafter, also referred to as a pixel region) **23**, and a control circuit (control region) **24** are formed on a region to be provided as each microchip part of a first semiconductor wafer (hereinafter, also referred to as a semiconductor substrate) **31**. In other words, a photodiode (PD), which acts as a photoelectric conversion part of each pixel, is formed on a region to be formed as each microchip part of the semiconductor substrate (for example, a silicon substrate) **31**. Then, a source/drain region **33** of each pixel transistor is formed on a semiconductor well region **32** in the semiconductor substrate **31**. The semiconductor well region **32** is formed by introduction of first-conductivity type (e.g., p-type) impurities and the source/drain region **33** is formed by introduction of second-conductivity type (e.g., n-type) impurities. The photodiode (PD) and the source/drain region **33** of each pixel transistor are formed by ion implantation from the surface of the substrate **31**.

The photodiode (PD) includes an n-type semiconductor region **34** and a p-type semiconductor region **35**. Here, the p-type semiconductor region **35** is on the surface side of the substrate **31**. On the surface of the substrate **31** forming the pixel, a gate electrode **36** is formed on a gate insulating layer. Pixel transistors Tr1 and Tr2 are formed by the gate electrode **36** and the paired source/drain regions **33**. In FIG. 4, for simplifying the explanation, two pixel transistors Tr1 and Tr2 are illustrated on behalf of a plurality of pixel transistors. The pixel transistor Tr1 adjacent to the photo-

diode (PD) is equivalent to a transfer transistor and the source/drain region thereof is equivalent to a floating diffusion (FD). The unit pixels **30** are separated from one another by isolation regions **38** respectively. The isolation regions **38** are formed by LOCOS (Local Oxidation of Silicon), STI (Shallow Trench Isolation), or using an impurity diffusion layer having a conductivity type different from that of a diffusion layer formed as a node. LOCOS is a process where the semiconductor substrate **31** is oxidized to form a silicon oxide layer. STI is a process of providing trenches in the semiconductor substrate **31** and filling the trenches with a silicon oxide layer.

On the other hand, on the control circuit (control region) **24**, MOS transistors that constitute a control circuit are formed on the semiconductor substrate **31**. FIG. 4 illustrates the MOS transistors that constitute the control circuit (control region) **24**, as represented by MOS transistors Tr3 and Tr4. Each of the MOS transistors Tr3 and Tr4 includes an n-type source/drain region **33** and a gate electrode **36** on a gate insulating layer.

Subsequently, a first insulating interlayer **39** is formed on the surface of the semiconductor substrate **31** and connection holes are then formed in the insulating interlayer **39**, followed by the formation of connection conductors **44** connecting to the desired transistors through the connection holes. The formation of the connection conductors **44** with different heights may be performed by stacking a first insulation thin layer **43a**, such as a silicon dioxide film, and a second insulation thin layer **43b**, such as a silicon nitride film, on the entire surface of the semiconductor substrate **31** including the upper surfaces of the respective transistors. Here, the second insulation thin layer **43b** acts as an etching stopper in an etching process for providing a contact hole connected to the gate electrode **36** and source/drain region **33** and afterward filled with a connection conductor **44**. The first insulating interlayer **39** is formed on the second insulation thin layer **43b**. Then, the connection holes with different depths are selectively formed in the first insulating interlayer **39**, reaching to the second insulation thin layer **43b** provided as the etching stopper. Subsequently, additional connection holes are formed in the respective portions of the first and second insulation thin layers **43a** and **43b** having the same film thickness by selective etching so that these additional connection holes can be communicated with the forgoing connection holes, respectively. After that, the connection conductor **44** is embedded in each of the resulting connection holes. In the case where the contact hole is provided without using the etching stopper, the second insulation thin layer **43b** may not be formed.

Next, a plurality of layers is formed in the insulating interlayer **39** so that the layers can be connected to the respective connection conductors **44**. In this example, but not limited to, a multi-wiring layer **41** is formed by the formation of three metal wiring layers **40**. The metal wiring layer **40** is formed of a copper (CU) wiring line. In general, each copper wiring line is covered with a barrier metal layer that prevents Cu from dispersing. Thus, a cap layer, a so-called protective layer **42**, of the copper wiring line **40** is formed on the multi-wiring layer **41**. In the aforementioned steps, the first semiconductor substrate **31** having the half-finished pixel region **23** and control circuit **24** is formed.

On the other hand, as shown in FIG. 5, a half-finished logic circuit **25** including a signal processing circuit for signal processing is formed on a region to be provided as each of microchip parts on a second semiconductor substrate (semiconductor wafer) **45**. Furthermore, on a p-type semiconductor well region **46** on the surface side of the second

11

semiconductor substrate (for example, the silicon wafer) **45**, a plurality of MOS transistors, which forms a logic circuit, is formed so that the MOS transistors can be separated from each other by isolation regions **50**, respectively. Here, the plurality of the MOS transistors is represented by MOS transistors **Tr6**, **Tr7**, and **Tr8**. Each of the MOS transistors **Tr6**, **Tr7**, and **Tr8** is formed using a pair of n-type source/drain regions **47** and a gate electrode **48** formed on a gate insulation layer. The logic circuit **25** can be constructed of CMOS transistors.

Subsequently, a first insulating interlayer **49** is formed on the surface of the semiconductor substrate **45** and connection holes are then formed in the insulating interlayer **49**, followed by the formation of connection conductors **54** connecting to the desired transistors through the respective connection holes. The formation of the connection conductors **54** with different heights may be performed by stacking a first insulation thin layer **43a**, such as a silicon dioxide film, and a second insulation thin layer **43b**, such as a silicon nitride film, are stacked on the entire surface of the semiconductor substrate **45** including the upper surfaces of the respective transistors. Here, the second insulation thin layer **43b** acts as an etching stopper.

The first insulating interlayer **49** is formed on the second insulation thin layer **43b**. Then, the connection holes with different depths are selectively formed in the first insulating interlayer **49**, reaching to the second insulation thin layer **43b** provided as an etching stopper. Subsequently, additional connection holes are formed in the respective portions of the first and second insulation thin layers **43a** and **43b** having the same film thickness by selective etching so that these additional connection holes can be communicated with the forgoing connection holes, respectively. After that, a connection conductor **44** is embedded in each of the resulting connection holes.

On the other hand, at a desired position on the area to be provided as each of microchip parts, a connection hole is formed from the surface of the first insulating interlayer **49** to a predetermined depth position in the semiconductor substrate **45**. Then, a connection conductor **51** for extraction electrode is embedded in the resulting connection hole. The connection conductor **51** may be made of copper (Cu), tungsten (W), polysilicon, or the like. Before embedding the connection conductor **51**, an insulation layer **52** is formed on the inner wall surface of the connection hole to insulate the connection conductor **51** from the semiconductor substrate **45**.

Next, a plurality of layers is formed through the insulating interlayer **49** so that they can be connected to the respective connection conductors **54** and the extraction connection conductor **51**. In this example, but not limited to, a multi-wiring layer **55** is formed by the formation of three metal wiring layers **53**. The metal wiring layer **53** is formed of a copper (CU) wiring line. In a manner similar to one described above, a cap layer, a so-called protective layer **56**, of the copper wiring line **53** is formed on the multi-wiring layer **49**. In the aforementioned steps, the first semiconductor substrate **45** having the half-finished logic circuit **25** is formed.

Next, as shown in FIG. 6, the first semiconductor substrate **31** and the second semiconductor substrate **45** are bonded together so that their respective multi-wiring layers **41** and **55** can be faced with each other. The bonding may be performed using plasma bonding, an adhesive agent, or the like. In the case of the plasma bonding, as shown in FIG. 7, a layer **57**, such as a plasma TEOS film, a plasma SiN film, a SiON film (block film), or a SiC film, is formed on the

12

bonding surface of each of the first and second semiconductor wafers **31** and **45**. The bonding surfaces with the layers **57** are subjected to a plasma treatment and then placed over one another, followed by being bonded by an annealing treatment. Such bonding processing is preferably performed using a low-temperature process at 400° C. or less. Such a range of the temperature will not affect on the bonding processing, wiring, or the like. In the case of the adhesive agent, as shown in FIG. 8, an adhesive layer **58** is formed on one of the bonding surfaces of the first and second semiconductor wafers **31** and **45** and both the wafers are then placed over one another through the adhesive layer **58**. In this example, the bonding is performed using the plasma bonding.

Next, as shown in FIG. 9, grinding and polishing are performed from the back side **31b** of the first semiconductor substrate **31** to make the first semiconductor substrate **31** into a thin film. The thin-film processing is performed to close in the photodiode (PD). After the thin-film processing, a p-type semiconductor layer for dark current control is formed on the back side of the photodiode (PD). For example, the semiconductor substrate **31** with a thickness of about 600 μm may be thinned to about 1 to 10 μm , preferably about 1 to 5 μm . The thin-film processing has been commonly performed using a separately prepared supporting substrate for bonding them together. In the embodiment, however, the second semiconductor substrate **45** on which the logic circuit **25** is formed is also used as a supporting substrate to make the first semiconductor substrate **31** into a thin film. After the thin-film processing, an insulating interlayer **59**, such as a silicon dioxide film, is formed on the backside of the substrate **31**. In the back-illuminated solid-state imaging device, the back side **31b** of the first semiconductor substrate **31** serves as a light-incident surface.

Next, as shown in FIG. 10, a connection through-hole **61** is formed in the thin-filmed first semiconductor substrate **31** at a desired position of a region to be provided as each microchip part. The connection through-hole **61** extends from the back side **31b** to the uppermost layer of the wiring **53** of the second semiconductor substrate **45** through the first semiconductor substrate **31**. Simultaneously, a connection hole **62** is formed near the connection through-hole **61** in the first semiconductor substrate **31**, extending from the back side **31b** to the first layer wiring **40** on the first semiconductor substrate **31**. Each of the connection through-hole **61** and connection hole **62** may have a contact area of 1 to 5 μm in diameter. Since the connection through-hole **61** and the connection hole **62** are formed after making the first semiconductor substrate **31** into a thin film, these holes **61** and **62** can be formed as micropores with a smaller aspect ratio. For example, each of the connection through-hole **61** and the connection hole **62** may have a contact depth of about 5 to 15 μm . Subsequently, an insulating layer **63** for electric insulation with the semiconductor substrate **31** is formed on the inner wall surface of each of the connection through-hole **61** and the connection hole **62**.

At this time, the process for manufacturing a pixel array is incomplete because the steps of forming an on-chip color filter and an on-chip microlens are still untouched. In addition, both the connection holes **61** and **62** may be processed and formed in the extension of the typical wafer process. In the case of the logic circuit, the process up to the uppermost layer wiring **53** suitable for a circuit technology has been completed, but the whole manufacturing process has not been completed. Therefore, a decrease in manufacturing cost can be attained.

13

Next, as shown in FIG. 11, a through-connection conductor 64 and a connection conductor 65 are embedded in the connection through-hole 61 and the connection hole 62, respectively. Each of the through-connection conductor 64 and the connection conductor 65 may be made of a metal, such as copper (Cu) or tungsten (W). After that, an insulating protective layer 66 is formed on the entire back side of the first semiconductor substrate 31. The insulating protective layer 66 may be made of, for example, a SiCN film, a plasma silicon nitride film, or a SiC film.

Next, as shown in FIG. 12, a light-shielding layer 67 is formed on a region to be shielded from light. In this figure, the light-shielding layer 67 is formed above the control circuit 24. Alternatively, it may be also formed above other pixel transistors. The light-shielding layer 67 may be a metal layer such as a tungsten film. The light-shielding layer 67 is electrically connected to the semiconductor well region 32 having a ground potential and prevented from being in an electrically floating state. In addition, since the light-shielding layer 67 electrically connected to the semiconductor well region 32 is provided with the ground potential, the semiconductor well region 32 is prevented from being in an electrically floating state. A passivation layer 68 is formed on the whole surface of the light-shielding layer 67 so that it entirely covers the light-shielding layer 67. The passivation layer 68 may be, for example, a plasma silicon nitride film or a CVD-SiN film. Subsequently, connection holes 69 are formed in the portions of the passivation layer 68 and the insulating protective layer 66, which correspond to the through-connection conductor 64 and the connection conductor 65, respectively. Then, connection wiring 72, an aluminum film, is formed on a barrier metal layer 71 on the connection hole 69. The barrier metal layer 71 is formed, for example, by a stacked film of Ti (downside)/TiN (upside). The connection wiring 72 is connected to both the through-connection conductor 64 and the connection conductor 65 through the barrier metal layer 71. The connection wiring 72 is used for connecting the pixel region 23 and the control circuit 24 to the logic circuit 25 and serves as an extraction electrode from the upper side, or serves as a so-called electrode pad. Hereinafter, the connection wiring 72 is also referred to as an electrode pad.

Therefore, an image sensor constructed of the image region 23 and the control circuit 24 formed on the first semiconductor substrate 31 is electrically connected to the logic circuit 25 formed on the second semiconductor substrate 45 through the connection conductor 65, the electrode pad 72, and the through-connection conductor 64. After that, a planarizing layer 73 is formed on these structural components.

Next, as shown in FIG. 13, red (R), green (G), and blue (B) on-chip color filters 74 are formed on the planarizing layer 73, corresponding to the respective pixels, and on-chip microlenses 75 are then formed on the respective color filters 74. In other words, both the on-chip color filters 74 and the on-chip microlenses 75 are formed so that each of them corresponds to each unit pixel of the pixel array. Here, to facilitate understanding of the embodiments of the present invention, FIG. 12 is an enlarged cross-sectional diagram illustrating the configuration of the substrate, but the on-chip color filters 74 and on-chip microlenses 75 are not shown in the figure. Thus, the pitch sizes of the on-chip color filters 74 and the on-chip microlenses 75 are reduced with reference to the pitch size of the unit pixels.

Next, although not illustrated in FIG. 13, the electrode pad 72 is exposed by selectively removing a lens material layer 75a and the planarizing layer 73. On the other hand, on the

14

side of the second semiconductor substrate 45, the surface of the substrate 45 is ground and polished to expose the surface of the connection conductor 51 that serves as an extraction electrode. After forming a passivation layer 76 on the exposed surface of the connection conductor 51 of the second semiconductor substrate 45, an opening 77 corresponding to the connection conductor 51 is formed in the passivation layer 76. A spherical electrode bump 78 is formed so that it can be electrically connected to the connection conductor 51 through the opening 77 (see FIG. 3). In the first semiconductor substrate 31, therefore, both the pixel region 23 and the control circuit 24 are brought into a finished product state. In the second semiconductor substrate 45, the logic circuit 25 is brought into a finished product state.

Subsequently, the resulting product is divided into the respective microchips, thereby obtaining a desired back-illuminated solid-state imaging device 79 as shown in FIG. 3.

In the solid-state imaging device 79 of the first embodiment, if the electrode pad 72 is used, the device 79 can be electrically connected to external wiring by wire bonding to the electrode pad 72. If the electrode bump 78 is used, the device 78 can be electrically connected to external wiring by face-down bonding. The user may choose one of the electrode pad 72 and the electrode bump 78 according to user's wishes.

In the first embodiment, the solid-state imaging device can be inspected using the electrode pad 72 with respect to the semiconductor wafers. In addition, the inspection includes two inspection steps, one in the state of wafer and the other in the final module state after cutting into chips.

According to the solid-state imaging device 79 and the manufacturing method thereof according to the first embodiment of the present invention, both the pixel region 23 and the control circuit 24 are formed on the microchip part from the first semiconductor substrate 31. In addition, the logic circuit 25 for signal processing is formed on the microchip part from the second semiconductor substrate 45. In this way, the functions of the pixel array and the functions of the logic circuit are assigned on different microchip parts, so that suitable processing technologies can be individually applied to the pixel array and the logic circuit. Therefore, the performances of the pixel array and the logic circuit can be efficiently exerted. Thus, a high-performance solid-state imaging device can be provided.

In the case of the configuration of the device shown in FIG. 2C, only the pixel region 23 for receiving incident light may be formed on the side of the semiconductor chip section 22. Thus, the control circuit 24 and the logic circuit 25 can be separately formed on the semiconductor chip section 26. Therefore, processing technologies suitable for the respective functional microchips can be independently selected while the surface area of the product module can be also reduced.

Since the pixel array and the logic circuit can be mounted in combination using the typical wafer-processing technology, the production of the device can be also facilitated.

The first semiconductor substrate 31 having the pixel region 23 and the control circuit 24 in a half-finished state and the second semiconductor substrate 45 having the logic circuit 25 in a half-finished state are attached together, followed by making the first semiconductor substrate 31 into a thin film. In other words, the second semiconductor substrate 45 may be used as a supporting substrate for making the first semiconductor substrate 31 into a thin film. Therefore, it becomes possible to reduce the number of

15

structural members and reduce the number of manufacturing steps. Furthermore, since the connection through-hole is formed during the thin-film formation, the aspect ratio of the hole can be reduced and the formation of connection holes can be performed with high accuracy. Furthermore, the through-connection conductor **61** and the connection conductor **62** are embedded into the connection through-hole and the connection hole of small aspect ratios. Therefore, the metal materials which can be used may include those with low coatability, such as copper (Cu), as well as those with high coatability, such as tungsten (W). In other words, the connection conductor materials hardly impose restrictions on the device. Thus, the pixel region and the control circuit can be electrically connected to the logic circuit with high precision. Therefore, it becomes possible to manufacture a high performance solid-state imaging device with high mass productivity while keeping production costs down.

3. Second Embodiment

Example of Configuration of Solid-State Imaging Device

Referring now to FIG. **14**, a solid-state imaging device (i.e., a MOS solid-state imaging device) according to a second embodiment of the present invention will be described. The solid-state imaging device **81** according to the second embodiment of the present invention is constructed in a manner similar to that of the first embodiment, except for the followings: In this embodiment, only the electrode pad **72** on the side of the first semiconductor substrate **31** is formed, while the connection conductor **51**, the insulating layer **52**, and the electrode bump **78** on the side of the second semiconductor substrate **45** are omitted. In addition, a passivation layer **76** is formed on the back side of the second semiconductor substrate **45**. Other structural components are the same as those described in the first embodiment. Therefore, the corresponding structural components are designated by the same reference numerals as those in FIG. **3** to omit the duplicated explanations thereof. In addition, the manufacture of the solid-stage imaging device **81** is performed by the same method as that of the first embodiment shown in FIG. **4** to FIG. **13**, except for the followings: The method of the present embodiment does not include the steps of forming the connection conductor **51**, the insulating layer **52**, and the electrode bump **78** as well as the formation of the connection hole desired for forming the connection conductor **51**.

The solid-state imaging device of the second embodiment exerts the same advantageous effects as those of the first embodiment because of having the similar configuration to that of the first embodiment except for the electrode bump **78**. In the second embodiment, the connection hole, the insulating layer **62**, and the connection conductor **61** are not formed on the side of the logic circuit in advance. Thus, lower costs can be expected.

4. Third Embodiment

Example of Configuration of Solid-State Imaging Device

Referring now to FIG. **15**, a semiconductor device (i.e., a MOS solid-state imaging device) according to a third embodiment of the present invention will be described. In the solid-state imaging device **83** of the third embodiment, the pixel region **23** and the control circuit **24** formed on the

16

side of the first semiconductor substrate **31** are electrically connected to the logic circuit **25** on the side of the second semiconductor substrate **45** through one through-connection conductor **84** formed in the first semiconductor substrate **31**.

In other words, a connection through-hole **85** is formed such that it extends from the back side **31b** of the first semiconductor substrate to the uppermost layer of the wiring **53** of the second semiconductor substrate **45** through the first semiconductor substrate **31**. In addition, part of the connection through-hole **85** reaches to the uppermost layer of the wiring **40** of the first semiconductor substrate **31**. After the formation of the insulating layer **63** on the inner wall surface of the connection through-hole **85**, the through-connection conductor **84** is embedded in the connection through-hole **85** to connect the wiring **40** on the side of the pixel region **23** and the control circuit **24** to the wiring **53** on the side of the logic circuit **25**. In the above first embodiment, the connection conductor **65** is connected to the first layer of the wiring **40** while the connection conductor **65** serves as a connection end. However, in the second embodiment, the through-connection conductor **84** is connected to the uppermost layer of the wiring **40**. The respective layers of the wiring **40** are connected to one another so that the uppermost layer thereof connected to the through-connection conductor **84** will serve as a connection end.

In the present embodiment, the pixel region **23** and the control circuit **24** are connected to the logic circuit **25** through one through-connection conductor **84**. Thus, an electrode pad **72** that serves as the uppermost layer of the connection wiring as described in the first embodiment is not formed.

Other structural components are the same as those described in the first embodiment. Therefore, the corresponding structural components are designated by the same reference numerals as those in FIG. **3** to omit the duplicated explanations thereof. In addition, the manufacture of the solid-stage imaging device **83** is performed by the same method as that of the first embodiment shown in FIG. **4** to FIG. **13**, except for the steps of forming the connection conductor **65** and the electric pad **72** and the steps of selectively etching the lens material layer **75a** and the planarizing layer **73**.

In the third embodiment, the solid-state imaging device can be inspected using the electrode pump from the connection conductor **51**.

According to the solid-state imaging device **83** of the third embodiment, the pixel region **23** and the control circuit **24** are electrically connected to the logic circuit **25** through one through-connection conductor **84**. In addition, the electrode pad **72** is omitted. Thus, the configuration of the device is simplified compared with that of the first embodiment. Furthermore, the number of the manufacturing steps can be reduced. Therefore, a further reduction in manufacturing costs can be attained. In addition, the same effects as those described in the first embodiment can be exerted.

5. Fourth Embodiment

Example of Configuration of Solid-State Imaging Device and Example of Manufacturing Method Thereof

Referring now to FIG. **16** and FIGS. **17** to **21**, a semiconductor device (i.e., a MOS solid-state imaging device) according to a fourth embodiment of the present invention and a manufacturing method thereof will be described.

17

In the fourth embodiment, first, as shown in FIG. 17, a half-finished image sensor, or a pixel region 23, and a control circuit 24 are formed on a region to be provided as each microchip part of a first semiconductor substrate 31. The manufacturing steps in the present embodiment are the same as those illustrated in FIG. 4 of the aforementioned first embodiment. The same reference numerals as in FIG. 4 are used to denote the corresponding or similar portions. Thus, redundant descriptions will be omitted. However, in the present embodiment, the multi-wiring layer 41 is formed on the first semiconductor substrate 31. However, the process is completed at the time of forming the uppermost layer of the wiring 40. In other words, the process is completed when the uppermost layer of the wiring 40 is exposed. The protective layer 42 shown in FIG. 4 is not formed on the exposed layer.

On the other hand, as shown in FIG. 18, a half-finished logic circuit 25 for signal processing circuit is formed on a region to be provided as each of microchip parts on a second semiconductor substrate 45. The manufacturing steps in the present embodiment are the same as those illustrated in FIG. 5 of the aforementioned first embodiment. The same reference numerals as in FIG. 5 are used to denote the corresponding structural components. Thus, redundant descriptions will be omitted. However, in the present embodiment, the multi-wiring layer 55 is formed on the second semiconductor substrate 45 and the process is completed at the time of forming the uppermost layer of the wiring 53. In other words, the process is completed when the uppermost layer of the wiring 53 is exposed. The protective layer 56 shown in FIG. 5 is not formed on the exposed layer.

Next, as shown in FIG. 19, the first semiconductor substrate 31 and the second semiconductor substrate 45 are bonded together so that their respective multi-wiring layers 41 and 55 can be faced with each other, while their wiring 40 and 53 are connected to each other and their insulating interlayers 39 and 49 are connected to each other. In this bonding process, the wiring 40 and 53 are copper (Cu) wiring and the insulating interlayers 39 and 40 are silicon dioxide films. Furthermore, both the semiconductor substrates 31 and 45 are placed over one another and heated while receiving a predetermined load while their respective Cu wirings 40 and 50 are directly touched with each other. Simultaneously, the insulating interlayers 39 and 49 may be connected with each other. The heating temperature at this time is, for example, about 300° C., which prevents Cu wiring from being deteriorated.

Next, as shown in FIG. 20, grinding and polishing are performed from the back side 31b of the first semiconductor substrate 31 to thin the first semiconductor substrate 31. The thin-film processing is performed to close in the photodiode (PD). After the thin-film formation, an insulating interlayer 59, such as a silicon dioxide film, is formed on the backside of the substrate 31. Subsequently, a connection hole 88 is formed in the thin-filmed first semiconductor substrate 31. The connection hole 88 is located at a desired position in a region to be provided as each microchip part and extends from the back side 31b of the substrate 31 to the first layer of the wiring 40. An insulating layer 63 is formed on the inner wall surface of the connection hole 88. Then, the connection hole 62 and the connection through-hole 61 are formed. The connection through-hole 61 reaches to the uppermost layer of the wiring 53 on the side of the second semiconductor substrate 45. Next, a through-connection conductor 64 and a connection conductor 65 are embedded in the connection through-hole 61 and the connection hole 62, respectively. After that, an insulating protective layer 66

18

is formed on the entire surface on the back side 31b of the first semiconductor substrate 31. The manufacturing steps illustrated in FIG. 20 are the same as those illustrated in FIGS. 9 to 11. The same reference numerals as in FIGS. 9 to 11 are used to denote the corresponding structural components. Thus, redundant descriptions will be omitted.

Next, as shown in FIG. 21, an electronic pad 72 and a light-shielding layer 67 are formed on the side of the first semiconductor substrate 31. Here, the electric pad 72 is connected to the connection conductor 62 and the through-connection conductor 61. Furthermore, a planarizing layer 73, an on-chip color filter 74, and an on-chip microlens 74 are formed on the same side. On the other hand, on the side of the second semiconductor substrate 45, the back side of the substrate is ground and polished to expose the connection conductor 51. A passivation layer 76 is formed and an electrode bump 78 is then formed on the connection conductor 51 (see FIG. 16). The manufacturing steps illustrated in FIG. 21 are the same as those illustrated in FIG. 13 as described above. The same reference numerals as in FIG. 13 are used to denote the corresponding structural components. Thus, redundant descriptions will be omitted.

Subsequently, the resulting product is divided into the respective microchips, thereby obtaining a desired back-illuminated solid-state imaging device 91 as shown in FIG. 16. In this embodiment, the configuration of the device illustrated in FIG. 2B is employed. Alternatively, the configuration of the device illustrated in FIG. 2C may be employed.

According to the solid-state imaging device 91 and the manufacturing method thereof according to the fourth embodiment of the present invention, in the step of combining the first semiconductor substrate 31 and the second semiconductor substrate 45, simultaneously, the wiring 40 and the wiring 53 are directly connected to each other. Thus, the pixel region 23 and the control circuit 24 are electrically connected to the logic circuit 25, completing their electrical connection. Therefore, the number of the manufacturing steps can be further reduced and a further reduction in manufacturing costs can be also attained. In addition, the device of the present embodiment exerts the same advantageous effects as those described in the first embodiment.

6. Fifth Embodiment

Example of Configuration of Semiconductor Device and Example of Manufacturing Method Thereof

Referring now to FIG. 22 and FIGS. 23 to 28, a semiconductor device and a manufacturing method thereof in accordance with the fifth embodiment of the present invention will be described. The semiconductor device of the present embodiment is a semiconductor device on which a first semiconductor integrated circuit and a second semiconductor integrated circuit are mounted in combination.

In the fifth embodiment, first, as shown in FIG. 23, a half-finished first semiconductor integrated circuit (logic circuit 102 in this example) is formed on a region to be provided as each of microchip parts on a first semiconductor substrate (semiconductor wafer) 101. In other words, on the region to be provided as each of microchip parts on the semiconductor well region 104 formed in the semiconductor substrate (e.g., silicon substrate) 103, a plurality of MOS transistors Tr11, Tr12, and Tr13 are formed. Each of the MOS transistors Tr11 to Tr13 includes a pair of source/drain regions 105 and a gate electrode 106 with a gate insulating layer placed therebetween. The MOS transistors Tr11 to

Tr13 are separated from one another by the presence of isolation regions 107, respectively. Here, but not limited to, the MOS transistors are represented by MOS transistors Tr11 to Tr13. The logic circuit 102 includes CMOS transistors. Therefore, these MOS transistors may be n-channel MOS transistors or p-channel MOS transistors. Thus, when the n-channel MOS transistor is formed, an n-type source/drain region is formed on a p-type semiconductor well region. When a p-channel MOS transistor is formed, a p-type source/drain region is formed in an n-type semiconductor well region.

Furthermore, for example, the first semiconductor integrated circuit may be a semiconductor memory circuit instead of the logic circuit 102. In this case, the logic circuit to be used as a second semiconductor integrated circuit is subjected to the signal processing of the semiconductor memory circuit.

Next, a plurality of layers are formed on the conductive substrate 103 through an interlayer insulating layer 108. In this example, a multi-wiring layer 111 is formed by laminated three metal wiring layers 109. For example, the metal wiring 109 may be made of copper, or Cu wiring. In addition, the respective MOS transistors Tr11 to Tr13 are connected to one another through the desired first layer of the wiring 109 and a connection conductor 112. Furthermore, three layers of the wiring 109 are connected to one another through the connection conductor. A cap layer, a so-called protective layer 114 which prevents the copper wiring 109 from being dispersed, is formed on the multi-wiring layer 113.

On the other hand, as shown in FIG. 24, a half-finished second semiconductor integrated circuit, a logic circuit 117 is formed in a region to be provided as each microchip part of the second semiconductor substrate (semiconductor wafer) 116. In other words, as shown in FIG. 20, on the region to be provided as each of microchip parts on the semiconductor well region 119 formed in the semiconductor substrate (e.g., silicon substrate) 118, a plurality of n-channel MOS transistors Tr21, Tr22, and Tr23 are formed. Each of the MOS transistors Tr21 to Tr23 includes a pair of source/drain regions 121 and a gate electrode 122 with a gate insulating layer placed therebetween. The MOS transistors Tr21 to Tr23 are separated from one another by the presence of isolation regions 123, respectively. Here, but not limited to, the MOS transistors are represented by MOS transistors Tr21 to Tr23. The logic circuit 117 includes CMOS transistors. Therefore, these MOS transistors may be n-channel MOS transistors or p-channel MOS transistors. Thus, when the re-channel MOS transistor is formed, an n-type source/drain region is formed on a p-type semiconductor well region. When a p-channel MOS transistor is formed, a p-type source/drain region is formed in an n-type semiconductor well region.

Next, a plurality of layers is formed on the conductive substrate 118 through an interlayer insulating layer 124. In this example, a multi-wiring layer 126 is formed by laminated three metal wiring layers 125. For example, the metal wiring 125 may be made of copper, or Cu wiring. In addition, the respective MOS transistors Tr21 to Tr23 are connected to one another through the desired first layer of the wiring 125 and a connection conductor 112. Furthermore, three layers of the wiring 125 are connected to one another through the connection conductor.

On the semiconductor substrate 118, furthermore, at a desired position on the area to be provided as each of microchip parts, a connection hole is formed from the surface of the first insulating interlayer 124 to a predeter-

mined depth position in the semiconductor substrate 118. Then, a connection conductor 128 for extraction electrode is embedded in the resulting connection hole. The connection conductor 128 may be made of copper (Cu), tungsten (W), polysilicon, or the like. Before embedding the connection conductor 128, an insulation layer 129 is formed on the inner wall surface of the connection hole to insulate the connection conductor 128 from the semiconductor substrate 118. Then, a cap layer, a so-called protective layer 127 which prevent the copper wiring 125 from being dispersed, is formed on the multi-wiring layer 126.

Next, as shown in FIG. 25, the first semiconductor substrate 101 and the second semiconductor substrate 116 are bonded together so that their respective multi-wiring layers 111 and 126 can be faced with each other. Just as in the case with the aforementioned embodiment, the bonding may be performed using plasma bonding, an adhesive agent, or the like. In this example, on the bonding surface of each of the first and second semiconductor wafers 101 and 116, a layer 129, such as a plasma TEOS film, a plasma SiN film, a SiON film (block film), or a SiC film, is formed and bonded together by plasma bonding.

Next, as shown in FIG. 26, grinding and polishing are performed from the back side of the first semiconductor substrate 101 to thin the first semiconductor substrate 101. For example, the semiconductor substrate 101 with a thickness of 600 μm may be thinned to about 5 to 10 μm .

Next, as shown in FIG. 27, a connection through-hole 131 is formed in the thin-filmed first semiconductor substrate 101 at a desired position of a region to be provided as each microchip part. The connection through-hole 131 extends from the back side 101b to the uppermost layer of the wiring 125 of the second semiconductor substrate 116 through the first semiconductor substrate 101. Simultaneously, a connection hole 132 is formed near the connection through-hole 131 in the first semiconductor substrate 101, extending from the back side 101b to a first layer portion of wiring 109 on the first semiconductor substrate 101. Since the connection through-hole 131 and the connection hole 132 are formed after making the first semiconductor substrate 101 into a thin film, these holes 131 and 132 can be formed as micropores with a smaller aspect ratio. Subsequently, an insulating layer 133 for electric insulation with the semiconductor substrate 101 is formed on the inner wall surface of each of the connection through-hole 131 and the connection hole 132.

Next, a through-connection conductor 134 and a connection conductor 135 are embedded in the connection through-hole 131 and the connection hole 132, respectively. Each of the through-connection conductor 134 and the connection conductor 135 may be made of a metal, such as copper (Cu) or tungsten (W).

Next, as shown in FIG. 28, connection wiring 136 is formed on the back side of the first semiconductor substrate 101 to make a connection between the through-connection conductor 134 and the connection conductor 135. The first semiconductor integrated circuit 102 is electrically connected to the second semiconductor integrated circuit 117 through the connection conductor 135, the through-connection conductor 134, and the connection wiring 136. The connection wiring 136 serves as an electrode pad used as an extraction electrode. An insulating layer is applied to the surface except for the connection wiring 136 to form an overcoat layer 139. The overcoat layer 139 may be, for example, a plasma silicon nitride film. On the other hand, on the side of the second semiconductor substrate 116, the surface of the substrate 116 is ground to expose the surface of the connection conductor 128 that serves as an extraction

21

electrode. After forming a passivation layer 137 on the exposed surface of the connection conductor 128 of the second semiconductor substrate 116, a spherical electrode bump 138 is formed so that it can be electrically connected to the connection conductor 128 (see FIG. 22).

Subsequently, the resultant is divided into each chip and semiconductor device 140 to be shown in FIG. 22 is obtained.

According to the semiconductor device 140 and the manufacturing method thereof according to the fifth embodiment of the present invention, just as in the case with the aforementioned embodiments, the first semiconductor integrated circuit and the second semiconductor integrated circuit can be independently formed on different microchip parts by their optimal process technologies, respectively. Therefore, a high-performance semiconductor integrated circuit can be provided. In addition, a reduction in manufacturing costs can be attained by bonding and thinning the first and second semiconductor wafers together in a half-finished product state, electrically connecting the first and second integrated circuits to each other, and dividing the resulting combination in a completed product state into microchips.

In the fifth embodiment, just as in the case with the fourth embodiment, the first and second semiconductor substrates may be bonded together to directly connect the wiring layers of multi-layered wiring to each other. Such a configuration of the device can lead to a decrease in number of manufacturing steps and a further reduction in manufacturing costs.

Although the solid-state imaging device according to any of the above embodiments uses electrons as signal electric charges, a p-type as a first-conductivity type, and an n-type as a second-conductivity type, it may be also applied to one using electron holes as signal electronic charges. In this case, the conductivity types of the semiconductor substrates, semiconductor well regions, or semiconductor regions are reversed. Thus, the n-type is provided as the first-conductivity type and the p-type is provided as the second-conductivity type.

In the solid-state imaging device according to any of the above embodiments, the first semiconductor chip section 22 may have a thickness smaller than the thickness of the second semiconductor chip section 26.

7. Sixth Embodiment

Example of Configuration of Electronic Apparatus

The solid-state imaging devices according to the embodiments of the present invention can be applied to electronic apparatuses including camera systems such as digital cameras and video cameras, cellular phones with imaging functions, other apparatuses with imaging functions, and so on.

FIG. 29 illustrates the configuration of a camera as an exemplary electronic apparatus according to the sixth embodiment of the present invention. An example of the camera according to the present embodiment is a video camera which can shoot a still picture or video. The camera 141 of the present embodiment includes a solid-state imaging device 142, an optical system 143 that introduces incident light into a photoreceptor of the solid-state imaging device 142, and a shutter device 144. Furthermore, the camera 141 includes a drive circuit 145 for driving the solid-state imaging device 142 and a signal processing circuit 146 for processing an output signal from the solid-state imaging device 142.

22

The solid-state imaging device 142 is any of the solid-state imaging devices of the aforementioned embodiments. The optical system (optical lens) 143 carries out image formation of image light (incident light) from a photographic subject onto an imaging surface of the solid-state imaging device 142. Therefore, signal electric charges are accumulated in the solid-state imaging device 142 for a given period of time. The optical system 143 may be an optical lens system constructed of a plurality of optical lenses. The shutter device 144 controls a period of light irradiation on the solid-state imaging device 142 and a period of light shielding.

The drive circuit 145 supplies drive signals for controlling the transfer operation of the solid-state imaging device 142 and the shutter operation of the shutter device 144. The driving signals (timing signals) supplied from the drive circuit 145 allow the solid-state imaging device 142 to transmit signals. The signal-processing circuit 146 performs various kinds of signal processing. Video signals subjected to the signal processing are stored in a storage medium such as a memory or outputted to a monitor.

The electronic apparatus, such as a camera, according to the sixth embodiment of the present invention includes a high-performance solid-state imaging device 142 with a lower production cost. Therefore, an inexpensive and reliable electronic apparatus can be provided.

The present application contains subject matter related to that disclosed in Japanese Priority Patent Application JP 2009-068582 filed in the Japan Patent Office on Mar. 19, 2009, the entire content of which is hereby incorporated by reference.

It should be understood by those skilled in the art that various modifications, combinations, sub-combinations and alterations may occur depending on design requirements and other factors insofar as they are within the scope of the appended claims or the equivalents thereof.

What is claimed is:

1. A back-illuminated semiconductor device, comprising:
 - a first semiconductor wafer including:
 - a pixel array including a photodiode and at least one of a transfer transistor, a reset transistor, and an amplification transistor,
 - a first bonding layer including at least one of a plasma TEOS film, a plasma SiN film, SiON film, and SiC film, and
 - a first insulating layer including a plurality of wiring layers, wherein the first insulating layer is between the bonding layer and a light-incident surface of the first semiconductor wafer, and wherein at least one wiring layer of the plurality of wiring layers is connected to the pixel array;
 - a second semiconductor wafer including:
 - a logic circuit including a signal processing circuit,
 - a second insulating layer including a plurality of wiring layers, wherein at least one wiring layer of the plurality of wiring layers is electrically connected to the logic circuit, and
 - a second bonding layer including at least one of a plasma TEOS film, a plasma SiN film, SiON film, and SiC film, wherein the first bonding layer of the first semiconductor wafer and the second bonding layer of the second semiconductor wafer are bonded directly to each other using plasma bonding;
 - a through-connection conductor extending from a light-incident side of the first semiconductor wafer to the at least one wiring layer of the plurality of wiring

23

layers in the second semiconductor wafer by penetrating the first semiconductor wafer; and

- a third insulating layer disposed above the through-connection conductor, wherein the at least one wiring layer of the plurality of wiring layers of the first semiconductor wafer electrically connects the through-connection conductor to the pixel array.

2. The semiconductor device according to claim 1, further comprising a connection conductor disposed in the first semiconductor wafer and extending from the light-incident side of the first semiconductor wafer to the at least one wiring layer of the plurality of wiring layers in the first semiconductor wafer, the connection conductor electrically connecting the through-connection conductor to the at least one wiring layer of the plurality of wiring layers in the first semiconductor wafer.

3. The semiconductor device according to claim 2, wherein the through-connection conductor connects a lowermost wiring layer of the second semiconductor wafer and an uppermost wiring layer of the first semiconductor wafer.

4. The semiconductor device according to claim 2, wherein the third insulating layer is disposed on a top surface of the connection conductor.

5. The semiconductor device according to claim 2, further comprising a second connection conductor disposed in the second semiconductor wafer, wherein the second connection conductor electrically connects the through-connection conductor to an electrode bump.

6. The semiconductor device according to claim 5, wherein the electrode bump connects the second connection conductor to an external wiring.

7. The semiconductor device according to claim 2, further comprising a pad connected to the through-connection conductor and the connection conductor.

8. The semiconductor device according to claim 2, wherein the through-connection conductor is located outside of a pixel region in which the pixel array is located.

9. The semiconductor device according to claim 1, wherein the first semiconductor wafer has a thickness smaller than that of the second semiconductor wafer.

10. The semiconductor device according to claim 1, wherein the through-connection conductor extends through the bonding layer of the first semiconductor wafer and the bonding layer of the second semiconductor wafer.

11. The semiconductor device according to claim 1, wherein at least one photodiode of the pixel array is configured to receive incident light from an optical system.

12. An electronic apparatus, comprising:

an imaging device, including:

a first semiconductor wafer including:

- a pixel array including a photodiode and at least one of a transfer transistor, a reset transistor, and an amplification transistor,

- a first bonding layer including at least one of a plasma TEOS film, a plasma SiN film, SiON film, and SiC film, and

- a first insulating layer including a plurality of wiring layers, wherein the first insulating layer is between the bonding layer and a light-incident surface of the first semiconductor wafer, and wherein at least

24

one wiring layer of the plurality of wiring layers is connected to the pixel array;

a second semiconductor wafer including:

- a logic circuit including a signal processing circuit,
- a second insulating layer including a plurality of wiring layers, wherein at least one wiring layer of the plurality of wiring layers is electrically connected to the logic circuit, and

- a second bonding layer including at least one of a plasma TEOS film, a plasma SiN film, SiON film, and SiC film, wherein the first bonding layer of the first semiconductor wafer and the second bonding layer of the second semiconductor wafer are bonded directly to each other using plasma bonding;

- a through-connection conductor extending from a light-incident side of the first semiconductor wafer to the at least one wiring layer of the plurality of wiring layers in the second semiconductor wafer by penetrating the first semiconductor wafer; and

- a third insulating layer disposed above the through-connection conductor, wherein the at least one wiring layer of the plurality of wiring layers of the first semiconductor wafer electrically connects the through-connection conductor to the pixel array; and
- an optical system that introduces incident light into a photodiode in the imaging device.

13. The electronic apparatus according to claim 12, further comprising a connection conductor disposed in the first semiconductor wafer and extending from the light-incident side of the first semiconductor wafer to the at least one wiring layer of the plurality of wiring layers in the first semiconductor wafer, the connection conductor electrically connecting the through-connection conductor to the at least one wiring layer of the plurality of wiring layers in the first semiconductor wafer.

14. The electronic apparatus according to claim 13, wherein the through-connection conductor connects a lowermost wiring layer of the second semiconductor wafer and an uppermost wiring layer of the first semiconductor wafer.

15. The electronic apparatus according to claim 13, wherein the third insulating layer is disposed on a top surface of the connection conductor.

16. The electronic apparatus according to claim 13, further comprising a second connection conductor, wherein the second connection conductor electrically connects the through-connection conductor to an electrode bump.

17. The electronic apparatus according to claim 16, wherein the electrode bump connects the second connection conductor to an external wiring.

18. The electronic apparatus according to claim 13, further comprising a pad connected to the through-connection conductor and the connection conductor.

19. The electronic apparatus according to claim 12, wherein the through-connection conductor is located outside of a pixel region in which the pixel array is located.

20. The electronic apparatus according to claim 12, wherein the through-connection conductor extends through the bonding layer of the first semiconductor wafer and the bonding layer of the second semiconductor wafer.
