(57) **ABSTRACT**

There are provided a method of manufacturing a semiconductor device, a substrate processing apparatus, and a semiconductor device. The method allows rapid formation of a conductive film, which has a low concentration of impurities permeated from a source owing to its dense structure, and a low resistivity. The method is performed by simultaneously supplying two or more kinds of sources into a processing chamber to form a film on a substrate placed in the processing chamber. The method comprises: performing a first source supply process by supplying at least one kind of source into the processing chamber at a first supply flow rate; and performing a second source supply process by supplying the at least one kind of source into the processing chamber at a second supply flow rate different from the first supply flow rate.

METHOD OF MANUFACTURING SEMICONDUCTOR DEVICE AND SUBSTRATE PROCESSING APPARATUS

CROSS-REFERENCE TO RELATED PATENT APPLICATION

This U.S. non-provisional patent application is a continuation of U.S. patent application Ser. No. 12/849,398, filed Aug. 3, 2010; claims priority under 35 U.S.C. §119 of Japanese Patent Applications No. 2009-181637, filed on Aug. 4, 2009 and No. 2010-160873, filed on Jul. 15, 2010, in the Japanese Patent Office, the entire contents of which are hereby incorporated by reference.

BACKGROUND OF THE INVENTION

1. Field of the Invention

The present invention relates to a method of manufacturing a semiconductor device, a substrate processing apparatus, and a semiconductor device. More particularly, the present invention relates to a method of manufacturing a semiconductor device, the method including a process of forming a conductive film or an insulating film on a substrate (wafer) by using a metal halide compound or an organic metal compound as a source, a substrate processing apparatus configured to form a metal film or a metal compound film on a substrate, and a semiconductor device.

2. Description of the Related Art

As a method of forming a predetermined film on a substrate, there is a chemical vapor deposition (CVD) method. In a CVD method, two or more sources are caused to react with each other in a gaseous state or on the surface of a substrate to form a film including elements of source molecules on the substrate. As another method of forming a predetermined film on a substrate, there is an atomic layer deposition (ALD) method. In an ALD method, two or more film-forming sources are alternately supplied to a substrate under predetermined film formation conditions (temperature, time, etc.), and the sources are adsorbed on the substrate on an atomic layer basis to form a film by a surface reaction. As compared with a conventional CVD method, a process can be performed at a lower substrate temperature (process temperature), and the thickness of a film formed on the substrate can be controlled by adjusting the execution number of a film-forming cycle.

As an example of a conductive film that can be formed on a substrate, Patent document 1 discloses a titanium nitride (TiN) film. In addition, there are examples of other conductive films such as a Ta film, an Al film, a W film, a Mn film, a film made of a nitride thereof, and a Ti film. In addition, examples of insulating films include a Hf, Zr, or Al oxide film, and a nitride film.

[Patent Document 1] International Publication No. WO2007/020874

When a titanium nitride film is formed on a substrate as a conductive film, for example, titanium tetrachloride ($TiCl_4$) may be used as a titanium (Ti)-containing source, and ammonia (NH_3) may be used as a nitriding gas. However, if a titanium nitride film is formed by a CVD method, as compared with the case of forming a titanium nitride film by an ALD method, problems such as high resistivity may be caused, for example, because chlorine (Cl) easily permeates the film.

On the other hand, if a continuous titanium nitride film is formed by an ALD method, as compared with the case where a titanium nitride film formed by a CVD method, the surface of the titanium nitride film may be smooth, and the resistance of the titanium nitride film may be relatively low. In addition, satisfactory step coverage may be obtained. However, since the film growth rate is low as compared with the case of using a CVD method, it takes time to obtain a desired film thickness, and thermal budge of a substrate increases.

SUMMARY OF THE INVENTION

An object of the present invention is to provide a method of manufacturing a semiconductor device, a substrate processing apparatus, and a semiconductor device. The method allows rapid formation of a conductive film, which has a low concentration of impurities permeated from a source owing to its dense structure, and a low resistivity.

According to an aspect of the present invention, there is provided a method of manufacturing a semiconductor device by simultaneously supplying a first source gas and a second source gas into a processing chamber to form a film on a substrate placed in the processing chamber, the method comprising: (a) supplying the second source gas into the processing chamber at a second flow rate while supplying the first source gas into the processing chamber at a first flow rate to form a first film on the substrate; and (b) supplying the second source gas into the processing chamber at a fourth flow rate lower than the second flow rate while supplying the first source gas into the processing chamber at a third flow rate lower than the first flow rate to form a second film on the substrate, wherein the step (a) through the step (b) are sequentially performed.

According to another aspect of the present invention, there is provided a substrate processing apparatus comprising: a processing chamber configured to accommodate a substrate; a source supply system configured to supply a first source gas and a second source gas into the processing chamber; and a control unit configured to control the source supply system to perform: (a) supplying the second source gas into the processing chamber at a second flow rate while supplying the first source gas into the processing chamber at a first flow rate to form a first film on the substrate; and (b) supplying the second source gas into the processing chamber at a fourth flow rate lower than the second flow rate while supplying the first source gas into the processing chamber at a third flow rate lower than the first flow rate to form a second film on the substrate, wherein the step (a) through the step (b) are sequentially performed.

According to another aspect of the present invention, there is provided a semiconductor device manufactured by a semiconductor device manufacturing method in which two or more kinds of sources are simultaneously supplied into a processing chamber to form a film on a substrate placed in the processing chamber, the method comprising: performed a first source supply process by supplying at least one kind of source into the processing chamber at a first supply flow rate; and performing a second source supply process by supplying the at least one kind of source into the processing chamber at a second supply flow rate different from the first supply flow rate.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. **1** is a schematic perspective view illustrating a substrate processing apparatus that can be properly used according to an embodiment of the present invention.

FIG. **2** is a schematic view illustrating a process furnace and surrounding members that can be properly used accord-

ing to an embodiment of the present invention, in which a vertical section of the process furnace is illustrated.

FIG. **3** is a sectional view taken along line A-A of the process furnace of FIG. **2** that can be properly used according to an embodiment of the present invention.

FIG. **4** is a view illustrating a gas supply sequence of a film forming process according to a first embodiment of the present invention.

FIG. **5** is a view illustrating a gas supply sequence of a film forming process according to a second embodiment of the present invention.

FIG. **6** is a view illustrating a gas supply sequence of a film forming process according to a third embodiment of the present invention.

FIG. **7** is a view illustrating a gas supply sequence of a film forming process according to a fourth embodiment of the present invention.

FIG. **8** is a view illustrating a gas supply sequence of a film forming process according to a fifth embodiment of the present invention.

FIG. **9** is a view illustrating a gas supply sequence of a film forming process according to a sixth embodiment of the present invention.

FIG. **10** is a flowchart for explaining a substrate processing process according to the first embodiment of the present invention.

FIG. **11** is a flowchart for explaining a substrate processing process according to the second embodiment of the present invention.

FIG. **12** is a flowchart for explaining a substrate processing process according to the third embodiment of the present invention.

FIG. **13** is a flowchart for explaining a substrate processing process according to the fourth embodiment of the present invention.

FIG. **14** is a flowchart for explaining a substrate processing process according to the fifth embodiment of the present invention.

FIG. **15** is a flowchart for explaining a substrate processing process according to the sixth embodiment of the present invention.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

Hereinafter, preferred embodiments of the present invention will be explained with reference to the attached drawings.

A substrate processing apparatus of the current embodiment is configured as an example of a semiconductor manufacturing apparatus used to fabricate semiconductor devices (integrated circuits, ICs). In the following description, an explanation will be given on a vertical apparatus as an example of the substrate processing apparatus configured to perform a process such as a film forming process on a substrate. However, the present invention is not limited to the use of the vertical type apparatus. For example, the present invention can be applied to a single wafer type apparatus.

<Overall Structure of Apparatus>

As shown in FIG. **1**, in a substrate processing apparatus **101**, cassettes **110** are used to accommodate substrates such as wafers **200**. The wafers **200** are made of a material such as silicon. The substrate processing apparatus **101** includes a case **111**. In the case **111**, a cassette stage **114** is installed. The cassettes **110** are configured to be carried onto the cassette stage **114**, or carried away from the cassette stage **114**, by an in-process carrying device (not shown).

On the cassette stage **114**, a cassette **110** is placed by the in-process carrying device in a manner such that wafers **200** are vertically positioned in the cassette **110** and a wafer entrance of the cassette **110** is pointed upward. The cassette stage **114** is configured so that the cassette **110** is rotated 90° counterclockwise in a longitudinal direction to the backward of the case **111** so as to horizontally orient the wafers **200** of the cassette **110** and point the wafer entrance of the cassette **110** to the backward of the case **111**.

Near the inner center part of the case **111** in a front-to-back direction, a cassette shelf **105** is installed. The cassette shelf **105** is configured to store a plurality of the cassettes **110** in a plurality of stages and a plurality of rows. At the cassette shelf **105**, a transfer shelf **123** is installed to store cassettes **110** that are carrying objects of a wafer transfer mechanism **125**.

At the upper side of the cassette stage **114**, a standby cassette shelf **107** is installed. The standby cassette shelf **107** is configured to store standby cassettes **110**.

Between the cassette stage **114** and the cassette shelf **105**, a cassette carrying device **118** is installed. The cassette carrying device **118** includes a cassette elevator **118*a*** capable of moving upward and downward while holding a cassette **110**, and a cassette carrying mechanism **118*b***. The cassette carrying device **118** is configured to carry cassettes **110** among the cassette stage **114**, the cassette shelf **105**, and the standby cassette shelf **107** by continuous motions of the cassette elevator **118*a*** and the cassette carrying mechanism **118*b***.

At the backside of the cassette shelf **105**, the wafer transfer mechanism **125** is installed. The wafer transfer mechanism **125** includes a wafer transfer device **125*a*** capable of rotating or linearly moving wafers **200** in a horizontal direction, and a wafer transfer device elevator **125*b*** configured to move the wafer transfer device **125*a*** upward and downward. At the wafer transfer device **125*a***, tweezers **125*c*** are installed to pick up wafers **200**. The wafer transfer mechanism **125** is configured such that wafers **200** can be placed on the tweezers **125*c*** to charge the wafers **200** into a boat **217** or discharge the wafers **200** from the boat **217** by continuous motions of the wafer transfer device **125*a*** and the wafer transfer device elevator **125*b***.

At the upside of the rear part of the case **111**, a process furnace **202** is installed to perform a heat treatment process on wafers **200**, and the bottom side of the process furnace **202** is configured to be opened and closed by a furnace port shutter **147**.

At the downside of the process furnace **202**, a boat elevator **115** is installed to move the boat **217** upward to and downward from the process furnace **202**. An arm **128** is connected to an elevating table of the boat elevator **115**. A seal cap **219** is horizontally installed on the arm **128**. The seal cap **219** supports the boat **217** vertically, and is configured to seal the bottom side of the process furnace **202**.

The boat **217** includes a plurality of holding members and is configured to hold a plurality of wafers **200** (for example, about fifty to one hundred fifty wafers) horizontally in a state where the wafers **200** are vertically arranged with the centers of the wafers **200** being aligned.

At the upside of the cassette shelf **105**, a cleaning unit **134*a*** is installed to supply clean air as a purified atmosphere. The cleaning unit **134*a*** includes a supply fan and a dust filter to supply clean air to the inside of the case **111**.

At the left side end part of the case **111**, another cleaning unit **134***b* is installed to supply clean air. The cleaning system **134***b* includes a supply fan and a dust filter to supply clean air to the surrounding area of the wafer transfer device **125***a*, the boat **217**, and the like. After flowing around the wafer transfer device **125***a*, the boat **217**, and the like, the clean air is exhausted to the outside of the case **111**.

<Operation of Substrate Processing Apparatus>

Next, a main operation of the substrate processing apparatus **101** will be described.

A cassette **110** carried to the cassette stage **114** by the in-process carrying device (not shown) is placed on the cassette stage **114** in a state where wafers **200** inside the cassette **110** are vertically positioned and the wafer entrance of the cassette **110** is pointed upward. Thereafter, the cassette **110** is rotated counterclockwise by 90° in a longitudinal direction toward the backward of the case **111** by the cassette stage **114** so that the wafers **200** inside the cassette **110** are horizontally positioned and the wafer hole of the cassette **110** is pointed to the backward of the case **111**.

Then, the cassette **110** is automatically carried and placed by the cassette carrying device **118** to a specified shelf position of the cassette shelf **105** or the standby cassette shelf **107** where the **110** is temporarily stored. Thereafter, the cassette **110** is transferred to the transfer shelf **123** from the cassette shelf **105** or the standby cassette shelf **107** by the cassette carrying device **118**. Alternatively, the carry cassette **110** may be directly transferred to the transfer shelf **123** from the cassette stage **114**.

After the cassette **110** is transferred to the transfer shelf **123**, wafers **200** are picked up from the cassette **110** through the wafer entrance of the cassette **110** and are charged into the boat **217** by the tweezers **125***c* of the wafer transfer device **125***a*. After delivering the wafer **200** to the boat **217**, the wafer transfer device **125***a* returns to the cassette **110** so as to charge the next wafers **200** into the boat **217**.

After a predetermined number of wafers **200** are charged into the boat **217**, the bottom side of the process furnace **202** closed by the furnace port shutter **147** is opened by moving the furnace shutter **147**. Subsequently, the boat **217** in which a group of wafers **200** is held is loaded into the process furnace **202** by an ascending motion of the boat elevator **115**, and the bottom side of the process furnace **202** is closed by the seal cap **219**.

After the loading, a predetermined treatment process is performed on the wafers **200** charged in the process furnace **202**. Thereafter, the wafers **200** and the cassette **110** are carried to the outside of the case **111** in a reverse sequence of the above.

<Structure of Process Furnace>

Next, with reference to FIG. **2** and FIG. **3**, the process furnace **202** of the substrate processing apparatus **101** will be described.

As shown in FIG. **2** and FIG. **3**, at the process furnace **202**, a heater **207** is installed as a heating device (heating unit) to heat wafers **200**. The heater **207** includes an insulating member having a cylindrical shape with a closed top side, and a plurality of heating wires installed with respect to the insulating member to form a heating unit structure. Inside the heater **207**, a reaction tube **203** made of quartz is installed to process wafers **200**.

At the lower end of the reaction tube **203**, a manifold **209** made of a material such as stainless steel is installed in a manner such that an O-ring **220** is disposed therebetween as a sealing member. A bottom opening of the manifold **209** is hermetically closed by a cover such as the seal cap **219** with a sealing member such as an O-ring **220** being disposed therebetween. That is, at the lower side of the reaction tube **203**, the seal cap **219** is installed as a furnace port cover capable of hermetically closing a bottom opening of the reaction tube **203**. The seal cap **219** is configured to make contact with the bottom side of the reaction tube **203** in a perpendicular direction from the lower side. The seal cap **219** is made of a metal such as stainless steel and has a circular disk shape. On the surface of the seal cap **219**, the O-ring **220** is installed as a seal member configured to make contact with the bottom side of the reaction tube **203**. At the process furnace **202**, a processing chamber **201** is formed by at least the reaction tube **203**, the manifold **209**, and the seal cap **219**.

At a side of the seal cap **219** opposite to the processing chamber **201**, a rotary mechanism **267** is installed to rotate the boat **217**. A rotation shaft **255** of the rotary mechanism **267** penetrates the seal cap **219** and is connected to the boat **217** (described later) through a boat support **218** that supports the boat **217**. By rotating the boat **217** with the rotary mechanism **267**, wafers **200** can be rotated. The seal cap **219** is configured to be vertically moved by an elevator such as the boat elevator **115** installed outside the reaction tube **203**, so that the boat **217** can be loaded into and unloaded from the processing chamber **201**.

As shown in FIG. **1**, the boat **217** includes a bottom plate **210** fixed to the boat support **218**, a top plate **211** disposed at the top side of the boat **217**, and a plurality of pillars **212** installed between the bottom plate **210** and the top plate **211**. The boat **217** is configured to hold a plurality of wafers **200**. The plurality of wafers **200** are supported by the pillars **212** of the boat **217** in a state where the wafers **200** are arranged at regular intervals and horizontally oriented.

At the above-described process furnace **202**, in a state where a plurality of wafers **200** to be batch-processed are piled in multiple states inside the boat **217**, the boat **217** is inserted into the processing chamber **201** while being supported by the boat support **218**, and then the heater **207** heats the wafers **200** inserted in the processing chamber **201** to a predetermined temperature.

As shown in FIG. **2** and FIG. **3**, three gas supply pipes **310**, **320**, and **330** (a first gas supply pipe **310**, a second gas supply pipe **320**, and a third gas supply pipe **330**) are connected to the processing chamber **201** to supply source gases (reaction gases).

At the gas supply pipe **310**, a flow rate control device (flow rate control unit) such as a mass flow controller **312**, a vaporizing unit (vaporizing device) such as a vaporizer **700**, and an on-off valve such as a valve **314** are installed sequentially from the upstream side of the gas supply pipe **310**. The upstream end of a nozzle **410** (first nozzle **410**) is connected to the leading end (downstream end) of the gas supply pipe **310**. The nozzle **410** has an L-shape constituted by a vertical part and a horizontal part. The vertical part of the nozzle **410** extends in a vertical direction (stacked direction of wafers **200**) in the arc-shaped space between the reaction tube **203** constituting the processing chamber **201** and the wafers **200** along the inner wall of the reaction tube **203**. The horizontal part of the nozzle **410** is installed such that the horizontal part penetrates the side wall of the manifold **209**. A plurality of gas supply holes **410***a* are formed in the lateral side of the nozzle **410** to supply a source gas through the gas supply holes **410***a*. The sizes of the gas supply holes **410***a* are equal or varied from the lower side to the upper side, and the gas supply holes **410***a* are arranged at the same pitch.

In addition, a vent line **610**, which is connected to an exhaust pipe **231** (described later), and a valve **614** are

connected to the gas supply pipe **310** at a position between the vaporizer **700** and the valve **314**. When a source gas is not supplied into the processing chamber **201**, the source gas may be discharged to the vent line **610** through the valve **614** by opening the valve **614** in a state where the valves **314** and **324** are closed.

In addition, the downstream end of a carrier gas supply pipe **510** is connected to the downstream side of the valve **314** of the gas supply pipe **310** to supply an inert gas as a carrier gas. At the carrier gas supply pipe **510**, a mass flow controller **512** and a valve **514** are installed sequentially from the upstream side of the carrier gas supply pipe **510**.

In addition, the upstream end of the gas supply pipe **320** is connected to the gas supply pipe **310** between the valve **314** and a joint part of the vent line **610**. The valve **324** which is an on-off valve is installed at the gas supply pipe **320**. The upstream end of a nozzle **420** (second nozzle **420**) is connected to the leading end (downstream end) of the gas supply pipe **320**. The nozzle **420** has an L-shape constituted by a vertical part and a horizontal part. The vertical part of the nozzle **420** extends in a vertical direction (stacked direction of wafers **200**) in the arc-shaped space between the reaction tube **203** constituting the processing chamber **201** and the wafers **200** along the inner wall of the reaction tube **203**. The horizontal part of the nozzle **420** is installed such that the horizontal part penetrates the side wall of the manifold **209**. A plurality of gas supply holes **420***a* are formed in the lateral side of the nozzle **420** to supply a source gas through the gas supply holes **420***a*. The sizes of the gas supply holes **420***a* are equal or varied from the lower side to the upper side, and the gas supply holes **420***a* are arranged at the same pitch. In addition, it is preferable that the sizes (diameters) of the gas supply holes **410***a* are different from the sizes (diameters) of the gas supply holes **420***a*. For example, the sizes of the gas supply holes **410***a* are greater than the sizes of the gas supply holes **420***a*. Furthermore, in FIG. **2**, the vaporizer **700** and the mass flow controller **312** are connected to both the nozzles **410** and **420** as a common vaporizing unit and a common mass flow controller. However, separate vaporizing units and mass flow controllers may be connected independently to the nozzles **410** and **420**.

In addition, the downstream end of a carrier gas supply pipe **520** is connected to the downstream side of the valve **324** of the gas supply pipe **320** to supply an inert gas as a carrier gas. At the carrier gas supply pipe **520**, a mass flow controller **522** and a valve **524** are installed sequentially from the upstream side of the carrier gas supply pipe **520**.

At the gas supply pipe **330**, a flow rate control device (flow rate control unit) such as a mass flow controller **332**, and a valve **334** are installed sequentially from the upstream side of the gas supply pipe **330**. The upstream end of a nozzle **430** (third nozzle **430**) is connected to the leading end (downstream end) of the gas supply pipe **330**. The nozzle **430** has an L-shape constituted by a vertical part and a horizontal part. Like the nozzle **410**, the vertical part of the nozzle **430** extends in a vertical direction (stacked direction of wafers **200**) in the arc-shaped space between the reaction tube **203** constituting the processing chamber **201** and the wafers **200** along the inner wall of the reaction tube **203**. The horizontal part of the nozzle **430** is installed such that the horizontal part penetrates the side wall of the manifold **209**. A plurality of gas supply holes **430***a* are formed in the lateral side of the nozzle **430** to supply a source gas through the gas supply holes **430***a*. Like the gas supply holes **410***a*, the sizes of the gas supply holes **430***a* are equal or varied from the lower side to the upper side, and the gas supply holes **430***a* are arranged at the same pitch.

In addition, the downstream end of a carrier gas supply pipe **530** is connected to the downstream side of the valve **334** of the gas supply pipe **330** to supply an inert gas as a carrier gas. At the carrier gas supply pipe **530**, a mass flow controller **532** and a valve **534** are installed.

For example, if a source supplied from the gas supply pipe **310** is liquid, the liquid source is supplied to the vaporizer **700** while controlling the flow rate of the liquid source by using the mass flow controller **312**. A vaporized gas, which is a source gas (reaction gas) generated by vaporizing a liquid source at the vaporizer **700**, flows to the downstream side of the gas supply pipe **310** through the valve **314** where the vaporized gas is mixed with a carrier gas supplied from the carrier gas supply pipe **510**, and then the gas mixture is supplied into the processing chamber **201** through the nozzle **410**. In addition, by controlling the valves **314** and **324**, the vaporized gas which is a source gas (reaction gas) can be supplied into the processing chamber **201** either through the gas supply pipe **310** or the gas supply pipe **320** or both through the gas supply pipes **310** and **320**. In addition, if a source supplied from the gas supply pipe **310** is gas, the mass flow controller **312** may be replaced with a mass flow controller adapted to control the flow rate of gas, and the vaporizer **700** may be not used.

In addition, a source gas (reaction gas) supplied from the gas supply pipe **330** flows to the downstream side of the gas supply pipe **330** through the valve **334** while the flow rate of the source gas is controlled by the mass flow controller **332**, and then the source gas is mixed with a carrier gas supplied from the carrier gas supply pipe **530**. Then, the gas mixture is supplied into the processing chamber **201** through the nozzle **430**.

In the above-described structure, for example, a source such as a Ti source (e.g., titanium tetrachloride ($TiCl_4$), tetrakis(dimethylamido)titanium (TDMAT, $Ti[N(CH_3)_2]_4$), or tetrakis(diethylamino)titanium (TDEAT, $Ti[N(CH_2CH_3)_2]_4$) is introduced into the gas supply pipe **310**. For example, as a modification source, a nitriding source such as ammonia (NH_3), nitrogen (N_2), nitrous oxide (N_2O), monomethylhydrazine (CH_6N_2), or hydrogen (H_2) is introduced into the gas supply pipe **330**.

In the current embodiment, a source supply unit (source supply system) is constituted mainly by the gas supply pipe **310**, the mass flow controller **312**, the vaporizer **700**, the valve **314** (on-off valve), the nozzle **410**, the gas supply holes **410***a*, the gas supply pipe **320**, the valve **324**, the nozzle **420**, the gas supply holes **420***a*, the gas supply pipe **330**, the mass flow controller **332**, the valve **334**, the nozzle **430**, and the gas supply holes **430***a*. Furthermore, in the current embodiment, an inert gas supply unit (inert gas supply system) is constituted mainly by the carrier gas supply pipe **510**, the mass flow controller **512**, the valve **514**, the carrier gas supply pipe **520**, the mass flow controller **522**, the valve **524**, the carrier gas supply pipe **530**, the mass flow controller **532**, and the valve **534**.

At the reaction tube **203**, the exhaust pipe **231** is installed to exhaust the inside atmosphere of the processing chamber **201**. A pressure sensor **245** which is a pressure detector (pressure detecting part) configured to detect the inside pressure of the processing chamber **201**, an auto pressure controller (APC) valve **243** which is a pressure regulator (pressure regulating part), and a vacuum pump **246** which is a vacuum exhaust device are sequentially installed from the upstream side of the exhaust pipe **231**. By operating the vacuum pump **246** and controlling the degree of opening of

the APC valve **243** based on pressure information detected by the pressure sensor **245**, the inside of the processing chamber **201** can be vacuum-evacuated to a predetermined pressure (vacuum degree).

The APC valve **243** is an on-off valve, which can be opened and closed to start and stop vacuum evacuation of the inside of the processing chamber **201** and can be adjusted in degree of valve opening for pressure adjustment. An exhaust system is constituted mainly by the exhaust pipe **231**, the APC valve **243**, the vacuum pump **246**, and the pressure sensor **245**.

At the reaction tube **203**, a temperature sensor **263** is installed as a temperature detector. By controlling power supplied to the heater **207** based on temperature information detected by the temperature sensor **263**, desired temperature distribution can be obtained in the processing chamber **201**. Like the nozzles **410** and **420**, the temperature sensor **263** has an L-shape and is disposed along the inner wall of the reaction tube **203**.

At the center part inside the reaction tube **203**, the boat **217** is installed. As described above, the boat **217** is configured to be loaded into and unloaded from the reaction tube **203** by raising and lowering the seal cap **219** with the boat elevator **115**. In addition, as described above, the rotation shaft **255** of the (boat) rotary mechanism **267** is connected to the bottom side of the boat support **218** that supports the boat **217**, so as to improve processing uniformity by rotating the boat **217**. By operating the boat rotary mechanism **267**, the boat **217** supported by the boat support **218** can be rotated.

A controller **280** is connected to the above-described members such as the mass flow controllers **312**, **332**, **512**, **522**, and **532**, the valves **314**, **324**, **334**, **514**, **524**, **534**, **243**, and **614**, the heater **207**, the vacuum pump **246**, the boat rotary mechanism **267**, the boat elevator **115**, the pressure sensor **245**, and the temperature sensor **263**. The controller **280** is an example of a control unit (control device) used to control overall operations of the substrate processing apparatus **101**. For example, the controller **280** controls operations such as flow rate adjusting operations of the mass flow controllers **312**, **332**, **512**, **522**, and **532**; opening and closing operations of the valves **314**, **324**, **334**, **514**, **524**, **534**, and **614**; opening and closing operations of the valve **243** and a pressure adjusting operation of the valve **243** based on pressure information detected by the pressure sensor **245**; a temperature adjusting operation of the heater **207** based on temperature information detected by the temperature sensor **263**; start and stop operations of the vacuum pump **246**; a rotation speed adjusting operation of the boat rotary mechanism **267**; and an elevating operation of the boat elevator **115**.

<Method of Manufacturing Semiconductor Device>

Next, an explanation will be given on an exemplary method of forming an insulating film on a substrate by using the process furnace **202** of the substrate processing apparatus **101** in a semiconductor device manufacturing process such as a large scale integration (LSI) circuit manufacturing process. In the following description, the controller **280** controls parts of the substrate processing apparatus **101**.

First Embodiment

In the current embodiment, an explanation will be given on a method of forming a titanium nitride film on a substrate as a conductive film. FIG. **10** is a flowchart for explaining a substrate processing process as a semiconductor device manufacturing process according to the current embodiment. In addition, FIG. **4** is a view illustrating a gas supply sequence of a film forming process performed in the substrate processing process of the current embodiment.

According to the current embodiment, a titanium nitride film is formed on a substrate by two chemical vapor deposition (CVD) methods at different film growth rates. First, a titanium nitride film is formed on a wafer **200** in a first film forming process by a high-speed CVD method (step **11**). Next, a titanium nitride film is formed on the wafer **200** in a second film forming process by a low-speed CVD method which is realized by reducing the flow rate of a titanium-containing source relative to the flow rate of a nitriding gas while supplying the nitriding gas at a sufficient flow rate (step **12**). The first and second film forming processes are performed at least once in the same processing chamber **201** to form a titanium nitride layer on the wafer **200**. In the current embodiment, an explanation will be on an exemplary case of using $TiCl_4$ as a titanium (Ti)-containing source and NH_3 as a nitriding gas. Whether the film growth rate is high or low is determined by the supply amount of $TiCl_4$ which is a source gas. If the supply amount of a source gas is large, the film growth rate is high because the amount of adsorption (or amount of deposition) per unit time increases. On the other hand, if the supply amount of a source gas is small, the film growth rate is low because the amount of adsorption (or amount of deposition) per unit time decreases.

As shown in FIG. **10**, first, wafers **200** to be processed are charged into the boat **217** (wafer charging). Next, the boat elevator **115** is lifted to load the boat **217**, in which the wafers **200** are charged, into the processing chamber **201** and hermetically close the processing chamber **201** with the seal cap **219** (boat loading). After the wafers **200** are loaded, the rotary mechanism **267** is operated to rotate the wafers **200**.

Next, the APC valve **243** is opened in a state where the vacuum pump **246** is operated, so as to exhaust the inside of the processing chamber **201**. Subsequently, by controlling the degree of opening of the APC valve **243**, the inside pressure of the processing chamber **201** is adjusted to a predetermined level. Thereafter, the heater **207** is controlled to keep the inside of the processing chamber **201** at a temperature where a CVD reaction can occur, for example, in the range from 250° C. to 800° C. Preferably, the inside of the processing chamber **201** may be kept at a temperature lower than 700° C., more preferably, at 450° C. (Pressure and temperature adjustment). If the temperature of the wafers **200** reaches 450° C. and conditions such as a temperature condition are stabilized, the wafers **200** are processed according to a later-described sequence in a state where the inside of the processing chamber **201** is kept at 450° C.

To deposit a titanium nitride film by a CVD method, the controller **280** controls devices such as valves, mass flow controllers, and a vacuum pump to supply $TiCl_4$ and NH_3 into the processing chamber **201** according to predetermined timing so that the $TiCl_4$ and the NH_3 can exist together and cause a gaseous reaction (CVD reaction). Hereinafter, a film forming sequence will be explained in detail.

$TiCl_4$ is liquid at normal temperature. Thus, $TiCl_4$ may be supplied into the processing chamber **201** after vaporizing the $TiCl_4$ by heating the $TiCl_4$ or after vaporizing the $TiCl_4$ using the vaporizer **700**. That is, in the latter case, inert gas such as helium (He), neon (Ne), argon (Ar), or nitrogen (N_2) may be supplied as a carrier gas so that it passes through a $TiCl_4$ container of the vaporizer **700**, and then vaporized $TiCl_4$ may be supplied into the processing chamber **201**

together with the carrier gas. In the following description, the latter case will be explained as an example.

In the first film forming process (step **11**) and the second film forming process (step **12**) of the sequence, $TiCl_4$ and NH_3 are simultaneously supplied.

To supply $TiCl_4$ into the processing chamber **201**, $TiCl_4$ is supplied into the gas supply pipe **310** and/or the gas supply pipe **320** (that is, $TiCl_4$ is supplied into either the gas supply pipe **310** or the gas supply pipe **320** or both the gas supply pipes **310** and **320**), and a carrier gas is supply into the carrier gas supply pipe **510** and the carrier gas supply pipe **520**. Then, the valve **314** of the gas supply pipe **310** and/or the valve **324** of the gas supply pipe **320**, the valve **514** of the carrier gas supply pipe **510**, the valve **524** of the carrier gas supply pipe **520**, and the valve **243** of the exhaust pipe **231**. Carrier gas flows through the carrier gas supply pipe **510** and the carrier gas supply pipe **520**, and the flow rates of the carrier gas are controlled by the mass flow controllers **512** and **522**. $TiCl_4$ flows through the gas supply pipe **310** where the flow rate of the $TiCl_4$ is controlled by the mass flow controller **312** and the $TiCl_4$ is vaporized by the vaporizer **700**, and then the $TiCl_4$ is mixed with the carrier gas the flow rate of which is controlled. Then, the mixture is supplied into the processing chamber **201** through the gas supply holes **410***a* of the nozzle **410**. $TiCl_4$ directed to the gas supply pipe **320** is supplied into the processing chamber **201** through the gas supply holes **420***a* of the nozzle **420**.

The sizes of the gas supply holes **410***a* of the nozzle **410** may be greater than the sizes of the gas supply holes **420***a* of the nozzle **420**. In this case, since the sizes of the gas supply holes **410***a* are greater than the sizes of the gas supply holes **420***a*, in step **11** for forming a titanium nitride film by a high-speed CVD method, it may be preferable that $TiCl_4$ is supplied into the processing chamber **201** from the gas supply pipe **310** and the gas supply holes **410***a* of the nozzle **410** at a high flow rate, and in step **12** for forming a titanium nitride film by a low-speed CVD method, it may be preferable that $TiCl_4$ is supplied into the processing chamber **201** from the gas supply pipe **320** and the gas supply holes **420***a* of the nozzle **420** at a low flow rate.

In addition, NH_3 is supplied into the processing chamber **201** by supplying NH_3 to the gas supply pipe **330** and a carrier gas (N_2) to the carrier gas supply pipe **530**. The valve **334** of the gas supply pipe **330**, the valve **534** of the carrier gas supply pipe **530**, and the valve **243** of the exhaust pipe **231** are opened together. The carrier gas flows in the carrier gas supply pipe **530**, and the flow rate of the carrier gas is controlled by the mass flow controller **532**. The NH_3 flows in the gas supply pipe **330**, and the flow rate of the NH_3 is controlled by the mass flow controller **332**. Then the NH_3 is mixed with the carrier gas the flow rate of which is controlled, and the mixture is supplied into the processing chamber **201** through the gas supply holes **430***a* of the nozzle **430**.

Then, the $TiCl_4$ and NH_3 supplied into the processing chamber **201** are exhausted through the exhaust pipe **231**. At this time, the degree of opening of the valve **243** is properly controlled so as to keep the inside pressure of the processing chamber **201** in the range from 5 Pa to 50 Pa, for example, at 20 Pa. The supply flow rate of $TiCl_4$ is controlled by the mass flow controller **312** in the range from 0.8 g/min to 3.0 g/min when the $TiCl_4$ is supplied through the gas supply pipe **310** and in the range from 0.05 g/min to 0.3 g/min when the $TiCl_4$ is supplied through the gas supply pipe **320**. The supply flow rate of NH_3 is controlled by the mass flow controller **332** to the range from 0.3 slm to 15 slm. The wafers **200** are exposed to the $TiCl_4$ and NH_3 until films are formed on the wafers **200** to a desired thickness. At this time, the temperature of the heater **207** is set such that the temperature of the wafers **200** can be kept in the range from 250° C. to 800° C., for example, at 450° C. If the temperature of the wafers **200** is lower than, for example, 250° C., the rate of reaction between the $TiCl_4$ and NH_3 is low, and thus it is difficult to obtain a desired film thickness within a predetermined time for industrially practical use. Therefore, to cause a sufficient high-speed CVD reaction, it may be preferable that the temperature of the wafers **200** is kept in the range from 300° C. to 500° C.

Hereinafter, the first film forming process (step **11**) and the second film forming process (step **12**) will be explained in detail with reference to FIG. **10** and FIG. **4**.

(Step **11**)

In the first film forming process (step **11**), $TiCl_4$ and NH_3 are simultaneously supplied to form titanium nitride films on the wafers **200** by a high-speed CVD method. For example, $TiCl_4$ is supplied to the gas supply pipe **310**, NH_3 is supplied to the gas supply pipe **330**, and a carrier gas is supplied to the carrier gas supply pipe **510** and the carrier gas supply pipe **530**. That is, the valves **314** and **334** of the gas supply pipes **310** and **330**, the valves **514** and **534** of the carrier gas supply pipes **510** and **530**, and the valve **243** of the exhaust pipe **231** are opened together, and the valve **324** of the gas supply pipe **320** is closed. The carrier gas flows in the carrier gas supply pipes **510** and **530**, and the flow rates of the carrier gas are controlled by the mass flow controllers **512** and **532**.

The $TiCl_4$ flows in the gas supply pipe **310** where the flow rate of the TiCl4 is controlled by the mass flow controller **312** and the $TiCl_4$ is vaporized by the vaporizer **700**, and then the $TiCl_4$ is mixed with the carrier gas the flow rate of which is controlled. Then, while the mixture is supplied into the processing chamber **201** through the gas supply holes **410***a* of the nozzle **410**, the mixture is exhausted through the exhaust pipe **231**. The NH_3 flows in the gas supply pipe **330** where the flow rage of the NH_3 is controlled by the mass flow controller **332**, and then the NH_3 is mixed with the carrier gas the flow rate of which is controlled. Then, while the mixture is supplied into the processing chamber **201** through the gas supply holes **430***a* of the nozzle **430**, the mixture is exhausted through the exhaust pipe **231**.

At this time, the degree of opening of the valve **243** is properly controlled so as to keep the inside pressure of the processing chamber **201** in the range from 20 Pa to 50 Pa, for example, at 30 Pa. The supply flow rate of the $TiCl_4$ is controlled by the mass flow controller **312**, for example, in the range from 0.8 g/min to 1.5 g/min. The supply flow rate of NH_3 is controlled by the mass flow controller **332**, for example, in the range from 5.0 slm to 8.0 slm. The wafers **200** are exposed to the $TiCl_4$ and NH_3, for example, for 5 seconds to 30 seconds.

At this time, gases flowing in the processing chamber **201** are $TiCl_4$, NH_3, and inert gas such as N_2. Therefore, owing to a gaseous reaction (thermal CVD reaction) between the $TiCl_4$ and NH_3, titanium nitride layers are deposited on the surfaces or under-layer films of the wafers **200**. Herein, the term “titanium nitride layer” is used to denote a layer (film) made of titanium nitride, such as a continuous layer, a discontinuous layer, a thin film in which discontinuous layers are superimposed, and a thin film to which another element is added. In addition, a continuous layer made of titanium nitride may also be called “a titanium nitride thin film.”

At the same time, the valve **524** is opened to supply inert gas through the carrier gas supply pipe **520** which is con-

nected to the gas supply pipe **320**. By this, gases such as the $TiCl_4$ and NH_3 can be prevented from flowing to the gas supply pipe **320** from the processing chamber **201**.

(Step **12**)

In the second film forming process (step **12**), the supply flow rate of NH_3 is not changed but the supply flow rate of $TiCl_4$ is decreased to form titanium nitride films on the wafers **200** by a low-speed CVD method. The supply flow rate of $TiCl_4$ is decreased by supplying $TiCl_4$ not through the gas supply pipe **310** but only through the gas supply pipe **320** (in the case where the sizes of the gas supply holes **410***a* of the nozzle **410** are greater than the sizes of the gas supply holes **420***a* of the nozzle **420**). That is, the valve **314** of the gas supply pipe **310** is closed, and the valve **324** of the gas supply pipe **320** is opened. Alternatively, the supply flow rate of $TiCl_4$ may be decreased by another method: in step **11**, the valves **314** and **324** are opened to supply $TiCl_4$ through both the gas supply pipes **310** and **320**, and in step **12**, one of the valves **314** and **324** is closed. In addition, alternatively, the supply flow rate of $TiCl_4$ to the vaporizer **700** (the amount of vaporized gas) may be temporarily decreased by controlling the mass flow controller **312**. In addition, alternatively, a mass flow controller (not shown) may be installed between the downstream side of the vaporizer **700** of the gas supply pipe **310** and the upstream side of a joint position of the gas supply pipe **320** in order to decrease the supply flow rate of $TiCl_4$.

The $TiCl_4$ flows in the gas supply pipe **320** and is mixed with a carrier gas the flow rate of which is controlled, and while the mixture is supplied into the processing chamber **201** through the gas supply holes **420***a* of the nozzle **420**, the mixture is exhausted through the exhaust pipe **231**. The $TiCl_4$ is supplied into the processing chamber **201** in a supply flow rate range where a low-speed CVD reaction can occur, for example, in the range from 0.05 g/min to 0.3 g/min. The wafers **200** are exposed to the $TiCl_4$ and NH_3, for example, for 15 seconds to 120 seconds. Titanium nitride films formed at this time have a small amount of residue Cl and low-resistance, dense, continuous features as compared with the titanium nitride films formed by the high-speed CVD method. In addition, as compared with the amount of film formation, sufficiently excessive NH_3 permeates into films so that the amount of Cl included in the inner high-speed CVD films can be reduced.

At the same time, in a state where the valve **514** is kept opened, inert gas is supplied through the carrier gas supply pipe **510** connected to the gas supply pipe **310**. By this, gases such as the $TiCl_4$ and NH_3 can be prevented from flowing to the gas supply pipe **310** from the processing chamber **201**.

The above-described step **11** and step **12** are set as one cycle, and the cycle is performed at least once to form titanium nitride films on the wafers **200** to a predetermined thickness by two different CVD methods.

After the film forming process is performed to a titanium nitride to a predetermined thickness, in a state where the valves **514**, **524**, and **534** are opened, the valves **314**, **324**, and **334** are closed to supply inert gas such as N_2 gas into the processing chamber **201** and exhaust the inert gas from the processing chamber **201** so as to purge the inside of the processing chamber **201** with the inert gas (purge). If the inside atmosphere of the processing chamber **201** is replaced with the inert gas (replacement with inert gas), the degree of opening of the APC valve **243** is adjusted so that the inside pressure of the processing chamber **201** can return to normal pressure (return to atmospheric pressure). Thereafter, the seal cap **219** is lowered by the boat elevator **115** to open the bottom side of the reaction tube **203** and unload the boat **217** in which the processed wafers **200** are held to the outside of the reaction tube **203** through the bottom side of the reaction tube **203** (boat unloading). Thereafter, the processed wafers **200** are discharged from the boat **217** (wafer discharging).

In a CVD method, the thickness of a titanium nitride film is controlled by the supply time of gas. As the supply time of gas is increased, a thicker film can be formed, and as the supply time of gas is decreased, a thinner film can be formed. At this time, it is controlled that the thickness of the titanium nitride film formed by the high-speed CVD method in step **11** is equal to or greater than half the total thickness of the titanium nitride film. The reason for this is as follows. If the thickness of the titanium nitride film formed by the low-speed CVD method is relatively great, the film forming time increases. That is, if the film thickness by the low-speed CVD is great, the film forming time increases to consequently lower the effects of relatively high speed and high quality.

According to the current embodiment, in step **12**, NH_3 is excessively supplied as compared with $TiCl_4$ to attain effects such as removal of Cl from titanium nitride films and improve the film quality. It may be preferable that the supply flow rate of NH_3 is higher than that of $TiCl_4$.

Furthermore, in the case where film formation is repeated while varying the supply ratio of NH_3 to $TiCl_4$, since the quality of titanium nitride films formed during a low pulse of the supply ratio (step **11**) is improved by an excessive amount of NH_3 supplied during a high pulse of the supply ratio (step **12**), the overall film quality can be uniformly maintained (with less unevenness) by controlling the supply flow rates of gases.

In addition, according to the current embodiment, two or more kinds of sources, for example, $TiCl_4$ and NH_3, are simultaneously supplied into the processing chamber **201**. The sentence 「two or more kinds of sources are simultaneously supplied into the processing chamber **201**」 means that two or more kinds of sources are supplied into the processing chamber **201** in a mixed state so that the sources can react with each other (chemical vapor reaction) in the processing chamber **201** or on the surfaces of substrates. As long as chemical vapor reaction can occur in the processing chamber **201** or on the surfaces of substrates, the opening and closing timings of the source supply system may be misaligned.

Second Embodiment

In the description of the current embodiment, an explanation will be given on the different with the first embodiment. FIG. **11** is a flowchart for explaining a substrate processing process as a semiconductor device manufacturing process according to the current embodiment. In addition, FIG. **5** is a view illustrating a gas supply sequence of a film forming process performed in the substrate processing process of the current embodiment.

In the film forming process of the first embodiment, a low-speed CVD method is used in the second film forming process (step **12**) in a way of not changing the supply flow rate of NH_3 but reducing the supply flow rate of $TiCl_4$. However, in a film forming process of the current embodiment, a low-speed CVD method is executed in a second film forming process (step **22**) in a way of reducing the supply flow rate of $TiCl_4$ but increasing the supply flow rate of NH_3.

(Step **21**)

In a first film forming process (step **21**) of the current embodiment, to form titanium nitride films on wafers **200** by using a high-speed CVD method, $TiCl_4$ and NH_3 are simul-

taneously supplied under the same conditions as those used in step **11** of the previous embodiment.

(Step **22**)

In the second film forming process (step **22**) of the current embodiment, to form titanium nitride films on the wafers **200** by a low-speed CVD method, the supply flow rate of $TiCl_4$ is decreased, and simultaneously the supply flow rate of NH_3 is increased. The supply flow rate of $TiCl_4$ is decreased, for example, by supplying $TiCl_4$ not through the gas supply pipe **310** but through the gas supply pipe **320**. That is, the valve **314** of the gas supply pipe **310** is closed, and the valve **324** of the gas supply pipe **320** is opened. The $TiCl_4$ flows in the gas supply pipe **320** and is mixed with a carrier gas the flow rate of which is controlled, and while the mixture is supplied into the processing chamber **201** through the gas supply holes **420***a* of the nozzle **420**, the mixture is exhausted through the exhaust pipe **231**. The $TiCl_4$ is supplied into the processing chamber **201** in a supply flow rate range where a low-speed CVD reaction can occur, for example, in the range from 0.05 g/min to 0.3 g/min.

Besides, in step **22**, the supply flow rate of NH_3 is controlled by the mass flow controller **332** to increase the supply flow rate of NH_3, for example, in the range from 6.0 slm to 15 slm. The wafers **200** are exposed to the $TiCl_4$ and NH_3, for example, for 15 seconds to 120 seconds. Titanium nitride films formed at this time have a small amount of residue Cl and low-resistance, dense, continuous features as compared with the titanium nitride films formed by the high-speed CVD method. In addition, as compared with the amount of film formation, sufficiently excessive NH_3 permeates into films so that the amount of Cl included in the inner high-speed CVD films can be reduced.

At the same time, in a state where the valve **514** is kept opened, inert gas is supplied through the carrier gas supply pipe **510** connected to the gas supply pipe **310**. By this, gases such as the $TiCl_4$ and NH_3 can be prevented from flowing to the gas supply pipe **310** from the processing chamber **201**.

The above-described step **21** and step **22** are set as one cycle, and the cycle is performed at least once to form titanium nitride films on the wafers **200** to a predetermined thickness by two different CVD methods.

In a CVD method, the thickness of a titanium nitride film is controlled by the supply time of gas. As the supply time of gas is increased, a thicker film can be formed, and as the supply time of gas is decreased, a thinner film can be formed. At this time, it is controlled that the thickness of the titanium nitride film formed by the high-speed CVD method in step **21** is equal to or greater than half the total thickness of the titanium nitride film. The reason for this is as follows. If the thickness of the titanium nitride film formed by the low-speed CVD method is relatively great, the film forming time increases. That is, if the film thickness by the low-speed CVD is great, the film forming time increases to consequently lower the effects of relatively high speed and high quality.

According to the current embodiment, in step **22**, NH_3 is more excessively supplied as compared with $TiCl_4$, so that effects such as removal of Cl from titanium nitride films can be attained and the film quality can be further improved. It may be preferable that the supply rate of NH_3 is higher than the supply flow rate of $TiCl_4$. Furthermore, in the case where film formation is repeated while varying the supply ratio of NH_3 to $TiCl_4$, since the quality of titanium nitride films formed during a low pulse of the supply ratio (step **21**) is improved by an excessive amount of NH_3 supplied during a high pulse of the supply ratio (step **22**), the overall film quality can be uniformly maintained (with less unevenness) by controlling the supply flow rates of gases.

That is, in the current embodiment, by increasing the supply flow rate of NH_3 in step **22**, the amount of residue Cl included in the titanium nitride films formed in step **22** can be further reduced, and since excessive NH_3 permeates the under-laying titanium nitride films formed in step **21**, the amount of residue Cl of the films can be further reduced. At this time, if the supply flow rate of NH_3 is higher, larger effects may be attained.

Furthermore, in step **21**, $TiCl_4$ and NH_3 may be simultaneously supplied under conditions different from those of the step **11**.

Third Embodiment

In the description of the current embodiment, an explanation will be given on the different with the second embodiment. FIG. **12** is a flowchart for explaining a substrate processing process as a semiconductor device manufacturing process according to the current embodiment. In addition, FIG. **6** is a view illustrating a gas supply sequence of a film forming process performed in the substrate processing process of the current embodiment.

In the film forming process of the second embodiment, a low-speed CVD method is used in the second film forming process (step **22**) in a way of decreasing the supply flow rate of $TiCl_4$ but increasing the supply flow rate of NH_3. However, in a film forming process of the current embodiment, the supply flow rate of $TiCl_4$ is reduced and the supply flow rate of NH_3 is reduced for a predetermined time in a second film forming process (step **32**); in a state where the supply flow rate of $TiCl_4$ is kept at the reduced level, only the supply flow rate of NH_3 is increased for a predetermined time in a third film forming process (step **33**); and in a state where the supply flow rate of $TiCl_4$ is kept at the reduced level, the supply flow rate of NH_3 is reduced again for a predetermined in a fourth film forming process (step **34**), so as to execute a low-speed CVD method.

(Step **31**)

In a first film forming process (step **31**) of the current embodiment, to form titanium nitride films on wafers **200** by using a high-speed CVD method, $TiCl_4$ and NH_3 are simultaneously supplied under the same conditions as those used in step **11** and step **21** of the previous embodiments.

(Step **32**)

In the second film forming process (step **32**) of the current embodiment, to form titanium nitride films on the wafers **200** by a first low-speed CVD method, the supply flow rate of $TiCl_4$ is decreased, and simultaneously the supply flow rate of NH_3 is also decreased. The supply flow rate of TiCl4 is decreased, for example, by supplying $TiCl_4$ not through the gas supply pipe **310** but through the gas supply pipe **320**. That is, the valve **314** of the gas supply pipe **310** is closed, and the valve **324** of the gas supply pipe **320** is opened. The $TiCl_4$ flows in the gas supply pipe **320** and is mixed with a carrier gas the flow rate of which is controlled, and while the mixture is supplied into the processing chamber **201** through the gas supply holes **420***a* of the nozzle **420**, the mixture is exhausted through the exhaust pipe **231**. The $TiCl_4$ is supplied into the processing chamber **201** in a supply flow rate range where a low-speed CVD reaction can occur, for example, in the range from 0.05 g/min to 0.3 g/min.

At the same time, the supply flow rate of NH_3 is controlled by the mass flow controller **332** so as to reduce the supply flow rate of NH_3, for example, in the range from 0.3 slm to 1.6 slm. In this way, in step **32**, the supply flow rates

of $TiCl_4$ and NH_3 are reduced while maintaining the supply ratio of $TiCl_4/NH_3$ similar to the supply ratio of $TiCl_4/NH_3$ in step **31**. By reducing the introducing amounts of $TiCl_4$ and NH_3 which are reactive gases, reaction products can be efficiently discharged to the outside of the processing chamber **201**. This may produce effects such as reduction of residue Cl and reduction of contaminants. The wafers **200** are exposed to the $TiCl_4$ and NH_3, for example, for 5 seconds to 30 seconds.

At this time, since the supply flow rate of $TiCl_4$ is similar to that in a low-speed CVD method, the growth rate of titanium nitride films may be similar to the growth rate of titanium nitride films by a low-speed CVD method, and since the supply ratio of $TiCl_4/NH_3$ is similar to that in a high-speed CVD method, the quality of the titanium nitride films may be similar to the film quality in a high-speed CVD method. However, the film quality may be improved as much as the film growth rate decreases. The film quality may have a medium quality between those of a titanium nitride formed by a high-speed CVD method and a titanium nitride formed by a low-speed CVD method.

At the same time, in a state where the valve **514** is kept opened, inert gas is supplied through the carrier gas supply pipe **510** connected to the gas supply pipe **310**. By this, gases such as the $TiCl_4$ and NH_3 can be prevented from flowing to the gas supply pipe **310** from the processing chamber **201**.

(Step **33**)

In the third film forming process (step **33**) of the current embodiment, to form titanium nitride films on the wafers **200** by a second low-speed CVD method, the supply flow rate of $TiCl_4$ is not changed (from the reduced level) but the supply flow rate of NH_3 is increased for a predetermined time. That is, the supply flow rate of NH_3 is controlled by the mass flow controller **332** to increase the supply flow rate of NH_3, for example, to the range from 5 slm to 15 slm in consideration of the first embodiment and the second embodiment. The wafers **200** are exposed to the $TiCl_4$ and NH_3, for example, for 15 seconds to 120 seconds.

At this time, the titanium nitride films formed in step **33** can have a low residue Cl concentration, and since excessive NH_3 permeates the under-laying titanium nitride films formed in step **31** and step **32**, the amount of reside Cl of the under-laying titanium nitride films can also be reduced.

(Step **34**)

In the fourth film forming process (step **34**) of the current embodiment, to form titanium nitride films on the wafers **200** by a third low-speed CVD method, the supply flow rate of $TiCl_4$ is not changed (from the reduced level) but the supply flow rate of NH_3 is reduced again for a predetermined time. That is, the supply flow rate of NH_3 is controlled by the mass flow controller **332** to decrease the supply flow rate of NH_3, for example, to the range from 0.3 slm to 5.0 slm. The wafers **200** are exposed to the $TiCl_4$ and NH_3, for example, for 5 seconds to 30 seconds. At this time, since the supply flow rate of $TiCl_4$ is similar to that in a low-speed CVD method, the growth rate of titanium nitride films may be similar to the growth rate of titanium nitride films by a low-speed CVD method. Since the supply ratio of $TiCl_4/NH_3$ is intermediate between that in a high-speed CVD method and that in a low-speed CVD method, the quality of the titanium nitride films may be intermediate between the quality of titanium nitride films formed by a high-speed CVD method and the quality of titanium nitride films formed by a low-speed CVD method.

The above-described step **31** to step **34** are set as one cycle, and the cycle is performed at least once to form titanium nitride films on the wafers **200** to a predetermined thickness by a plurality of different CVD methods.

In a CVD method, the thickness of a titanium nitride film is controlled by the supply time of gas. As the supply time of gas is increased, a thicker film can be formed, and as the supply time of gas is decreased, a thinner film can be formed. At this time, the thickness ratio of the titanium nitride film formed by the high-speed CVD method in step **31** and the titanium nitride films formed by the first to third low-speed CVD methods in step **32** to step **34** is controlled such that the thickness of the titanium nitride film formed by the high-speed CVD method is equal to or greater than half the total thickness of the titanium nitride films. The reason for this is as follows. If the thickness of the titanium nitride film formed by the low-speed CVD method is relatively great, the film forming time increases. That is, if the film thickness by the low-speed CVD is great, the film forming time increases to consequently lower the effects of relatively high speed and high quality.

According to the current embodiment, in step **33**, NH_3 is excessively supplied as compared with $TiCl_4$ to attain effects such as removal of Cl from titanium nitride films and improve the film quality. It may be preferable that the supply rate of NH_3 is higher than the supply flow rate of $TiCl_4$. Furthermore, in the case where film formation is repeated while varying the supply ratio of NH_3 to $TiCl_4$, since the quality of titanium nitride films formed during a low pulse of the supply ratio (step **31**, step **32**, or step **34**) is improved by an excessive amount of NH_3 supplied during a high pulse of the supply ratio (step **33**), the overall film quality can be uniformly maintained (with less unevenness) by controlling the supply flow rates of gases.

In addition, according to the current embodiment, since the supply flow rate of NH_3 is reduced in step **32** and step **34**, reaction products can be easily discharged from the processing chamber **201**, and since the supply flow rate of NH_3 is increased in step **33**, Cl can be removed to improve the quality of titanium nitride films.

Furthermore, in step **31**, $TiCl_4$ and NH_3 may be simultaneously supplied under conditions different from those of the step **11**.

Fourth Embodiment

In the description of the current embodiment, an explanation will be given on the different with the first embodiment. FIG. **13** is a flowchart for explaining a substrate processing process as a semiconductor device manufacturing process according to the current embodiment. In addition, FIG. **7** is a view illustrating a gas supply sequence of a film forming process performed in the substrate processing process of the current embodiment.

In the film forming process of the first embodiment, both $TiCl_4$ and NH_3 are continuously supplied in the first film forming process (step **11**) and the second film forming process (step **12**). However, in a film forming process of the current embodiment, before and after a second film forming process (step **43**), supplies of $TiCl_4$ and NH_3 into the processing chamber **201** are stopped, and gas removing processes (step **42** and step **44**) are performed to remove gases remaining in the processing chamber **201**.

(Step **41**)

In a first film forming process (step **41**) of the current embodiment, to form titanium nitride films on wafers **200** by a high-speed CVD method, $TiCl_4$ and NH_3 are simultaneously supplied under the same conditions as those used in step **11**, step **21**, and step **31** of the previous embodiments.

(Step **42**)

In the gas removing process (step **42**) of the current embodiment, the valves **314** and **334** of the gas supply pipes **310** and **330** are closed to stop supplies of $TiCl_4$ and NH_3 into the processing chamber **201**, and valve **614** is opened so that $TiCl_4$ can flow to the vent line **610**. In this way, supply of $TiCl_4$ into the processing chamber **201** is interrupted without stopping vaporization of $TiCl_4$ so that $TiCl_4$ can be supplied again rapidly and stably in step **43** (described later). At this time, the valve **243** of the gas exhaust pipe **231** is kept open, and the inside of the processing chamber **201** is exhausted to a pressure equal to or lower than 20 Pa by using the vacuum pump **246** so as to exhaust $TiCl_4$ and NH_3 remaining in the processing chamber **201**. At this time, if inert gas such as N_2 is supplied into the processing chamber **201**, the remaining $TiCl_4$ and NH_3 can be removed more efficiently.

(Step **43**)

In the second film forming process (step **43**) of the current embodiment, to form titanium nitride films on the wafers **200** by a low-speed CVD method like in step **12** of the first embodiment, the supply flow rate of NH_3 is not changed but only the supply flow rate of $TiCl_4$ is decreased.

(Step **44**)

In the gas removing process (step **44**) of the current embodiment, the valves **314** and **334** of the gas supply pipes **310** and **330** are closed to stop supplies of $TiCl_4$ and NH_3 into the processing chamber **201**, and valve **614** is opened so that $TiCl_4$ can flow to the vent line **610**. In this way, supply of $TiCl_4$ into the processing chamber **201** is interrupted without stopping vaporization of $TiCl_4$ so that $TiCl_4$ can be supplied again rapidly and stably when the step **41** is performed again. At this time, the valve **243** of the gas exhaust pipe **231** is kept open, and the inside of the processing chamber **201** is exhausted to a pressure equal to or lower than 20 Pa by using the vacuum pump **246** so as to exhaust $TiCl_4$ and NH_3 remaining in the processing chamber **201**. At this time, if inert gas such as N_2 is supplied into the processing chamber **201**, the remaining $TiCl_4$ and NH_3 can be removed more efficiently.

The above-described step **41** to step **44** are set as one cycle, and the cycle is performed at least once so that while removing gases from the processing chamber **201**, titanium nitride films can be formed on the wafers **200** to a predetermined thickness by a plurality of different CVD methods.

According to the current embodiment, in step **43**, NH_3 is excessively supplied as compared with $TiCl_4$ so as to attain effects such as removal of Cl from titanium nitride films and improve the film quality. It may be preferable that the supply rate of NH_3 is higher than the supply flow rate of $TiCl_4$.

Furthermore, in the case where film formation is repeated while varying the supply ratio of NH_3 to $TiCl_4$, since the quality of titanium nitride films formed during a low pulse of the supply ratio (step **41**) is improved by an excessive amount of NH_3 supplied during a high pulse of the supply ratio (step **43**), the overall film quality can be uniformly maintained (with less unevenness) by controlling the supply flow rates of gases.

In addition, according to the current embodiment, introduction of reactive gases (source gases) is stopped at intervals (step **42** and step **44**) when CVD film forming processes (step **41** and step **43**) are performed under different conditions, so that reaction products can be efficiently discharged to the outside of the processing chamber **201**. In the current embodiment, reaction products can be discharged more efficiently as compared with the third embodiment, and thus effects such as reduction of residue Cl and reduction of contaminants can be attained. In addition, separation of two kinds of CVD conditions reduces the possibility of formation of an asymptotical titanium nitride film the quality of which cannot be controlled when a flow rate is changed, and thus the film quality can be effectively controlled. However, since films are not formed during the intervals (step **42** and step **44**), throughput may be decreased. Which of the embodiments is optimal may be determined by the balance between film quality requirements and throughput requirement.

Fifth Embodiment

In the description of the current embodiment, an explanation will be given on the different with the second embodiment. FIG. **14** is a flowchart for explaining a substrate processing process as a semiconductor device manufacturing process according to the current embodiment. In addition, FIG. **8** is a view illustrating a gas supply sequence of a film-forming process performed in the substrate processing process of the current embodiment.

In the film forming process of the second embodiment, both $TiCl_4$ and NH_3 are continuously supplied in the first film forming process (step **21**) and the second film forming process (step **22**). However, in a film forming process of the current embodiment, before and after a second film forming process (step **53**), supplies of $TiCl_4$ and NH_3 into the processing chamber **201** are stopped, and gas removing processes (step **52** and step **54**) are performed to remove gases remaining in the processing chamber **201** (this is the same as in the fourth embodiment). In the second film forming process (step **53**) of the current embodiment, like the second embodiment, the supply flow rate of $TiCl_4$ is decreased but the supply flow rate of NH_3 is increased to execute a low-speed CVD method (this is different from the fourth embodiment).

(Step **51**)

In a first film forming process (step **51**) of the current embodiment, to form titanium nitride films on wafers **200** by using a high-speed CVD method, $TiCl_4$ and NH_3 are simultaneously supplied under the same conditions as those used in step **11**, step **21**, and step **31** of the previous embodiments.

(Step **52**)

In the gas removing position (step **52**) of the current embodiment, the valves **314** and **334** of the gas supply pipes **310** and **330** are closed to stop supplies of $TiCl_4$ and NH_3 into the processing chamber **201**, and valve **614** is opened so that $TiCl_4$ can flow to the vent line **610**. In this way, supply of $TiCl_4$ into the processing chamber **201** is interrupted without stopping vaporization of $TiCl_4$ so that $TiCl_4$ can be supplied again rapidly and stably in step **53** (described later). At this time, the valve **243** of the gas exhaust pipe **231** is kept open, and the inside of the processing chamber **201** is exhausted to a pressure equal to or lower than 20 Pa by using the vacuum pump **246** so as to exhaust $TiCl_4$ and NH_3 remaining in the processing chamber **201**. At this time, if inert gas such as N_2 is supplied into the processing chamber **201**, the remaining $TiCl_4$ and NH_3 can be removed more efficiently.

(Step **53**)

In the second film forming process (step **53**) of the current embodiment, to form titanium nitride films on the wafers **200** by a low-speed CVD method like in step **22** of the second embodiment, $TiCl_4$ and NH_3 are supplied into the processing chamber **201** in a state where the supply flow rate

of $TiCl_4$ is decreased as compared with that in step **51** and the supply flow rate of NH_3 is increased as compared with that in step **51**.

(Step **54**)

In the gas removing process (step **54**) of the current embodiment, the valves **314** and **334** of the gas supply pipes **310** and **330** are closed to stop supplies of $TiCl_4$ and NH_3 into the processing chamber **201**, and valve **614** is opened so that $TiCl_4$ can flow to the vent line **610**. In this way, supply of $TiCl_4$ into the processing chamber **201** is interrupted without stopping vaporization of $TiCl_4$ so that $TiCl_4$ can be supplied again rapidly and stably when the step **51** is performed again. At this time, the valve **243** of the gas exhaust pipe **231** is kept open, and the inside of the processing chamber **201** is exhausted to a pressure equal to or lower than 20 Pa by using the vacuum pump **246** so as to exhaust $TiCl_4$ and NH_3 remaining in the processing chamber **201**. At this time, if inert gas such as N_2 is supplied into the processing chamber **201**, the remaining $TiCl_4$ and NH_3 can be removed more efficiently.

The above-described step **51** to step **54** are set as one cycle, and the cycle is performed at least once so that while removing gases from the processing chamber **201**, titanium nitride films can be formed on the wafers **200** to a predetermined thickness by a plurality of different CVD methods.

According to the current embodiment, in step **53**, NH_3 is excessively supplied as compared with $TiCl_4$ to attain effects such as removal of Cl from titanium nitride films and improve the film quality. It may be preferable that the supply rate of NH_3 is higher than the supply flow rate of $TiCl_4$. Furthermore, in the case where film formation is repeated while varying the supply ratio of NH_3 to $TiCl_4$, since the quality of titanium nitride films formed during a low pulse of the supply ratio (step **51**) is improved by an excessive amount of NH_3 supplied during a high pulse of the supply ratio (step **53**), the overall film quality can be uniformly maintained (with less unevenness) by controlling the supply flow rates of gases.

In addition, according to the current embodiment, like in the fourth embodiment, introduction of reactive gases (source gases) is stopped at intervals (step **52** and step **54**) when CVD film forming processes (step **51** and step **53**) are performed under different conditions, so that reaction products can be efficiently discharged to the outside of the processing chamber **201**. In this way, substances such as Cl can be prevented from remaining in the titanium nitride films.

Sixth Embodiment

In the description of the current embodiment, an explanation will be given on the different with the first embodiment. FIG. **15** is a flowchart for explaining a substrate processing process as a semiconductor device manufacturing process according to the current embodiment. In addition, FIG. **9** is a view illustrating a gas supply sequence of a film-forming process performed in the substrate processing process of the current embodiment.

In the film forming process of the first embodiment, the second film forming process (step **11**) and the second film forming process (step **12**) are set as one cycle, and the cycle is performed predetermined times. However, in the current embodiment, after a first film forming process (step **61**) and a second film forming process (step **62**) are performed, a gas removing process (step **63**) is performed by stopping supplies of $TiCl_4$ and NH_3 into the processing chamber **201** and removing gases remaining in the processing chamber **201**. The step **61** to step **63** are set as one cycle, and the cycle is performed predetermined times. This is different from the first embodiment.

(Step **61**)

In the first film forming process (step **61**) of the current embodiment, to form titanium nitride films on wafers **200** by a high-speed CVD method like in step **11** of the first embodiment, $TiCl_4$ and NH_3 are simultaneously supplied into the processing chamber **201**.

(Step **62**)

In the second film forming process (step **62**) of the current embodiment, to form titanium nitride films on the wafers **200** by a low-speed CVD method like in step **22** of the second embodiment, $TiCl_4$ and NH_3 are supplied into the processing chamber **201** in a state where the supply flow rate of $TiCl_4$ is decreased as compared with that in step **61** and the supply flow rate of NH_3 is not changed as compared with that in step **61**.

(Step **63**)

In the gas removing process (step **63**) of the current embodiment, the valves **314** and **334** of the gas supply pipes **310** and **330** are closed to stop supplies of $TiCl_4$ and NH_3 into the processing chamber **201**, and valve **614** is opened so that $TiCl_4$ can flow to the vent line **610**. In this way, supply of $TiCl_4$ into the processing chamber **201** is interrupted without stopping vaporization of $TiCl_4$ so that $TiCl_4$ can be supplied again rapidly and stably when the step **61** and step **62** are performed again. At this time, the valve **243** of the gas exhaust pipe **231** is kept open, and the inside of the processing chamber **201** is exhausted to a pressure equal to or lower than 20 Pa by using the vacuum pump **246** so as to exhaust $TiCl_4$ and NH_3 remaining in the processing chamber **201**. At this time, if inert gas such as N_2 is supplied into the processing chamber **201**, the remaining $TiCl_4$ and NH_3 can be removed more efficiently.

The above-described step **61** to step **63** are set as one cycle, and the cycle is performed at least once so that while removing gases from the processing chamber **201**, titanium nitride films can be formed on the wafers **200** to a predetermined thickness by a plurality of different CVD methods.

According to the current embodiment, in step **62**, NH_3 is excessively supplied as compared with $TiCl_4$ so as to attain effects such as removal of Cl from titanium nitride films and improve the film quality. It may be preferable that the supply rate of NH3 is higher than the supply flow rate of $TiCl_4$. Furthermore, in the case where film formation is repeated while varying the supply ratio of NH_3 to $TiCl_4$, since the quality of titanium nitride films formed during a low pulse of the supply ratio (step **61**) is improved by an excessive amount of NH_3 supplied during a high pulse of the supply ratio (step **62**), the overall film quality can be uniformly maintained (with less unevenness) by controlling the supply flow rates of gases.

In addition, according to the current embodiment, like in the fourth embodiment, introduction of reactive gases (source gases) is stopped at intervals (step **62**) while CVD film forming processes (step **61** and step **62**) are repeated under different conditions, thereby making it possible to attaining effects such as efficient discharging of reaction products to the outside of the processing chamber **201**. In the case of removing remaining gases, disadvantageously, throughput may be decreased. However, like the current embodiment, if the gas removing process is performed once (that is, if the gas removing process is performed only after the step **62** instead of performing the gas removing process after the step **61** the step **62**, respectively), throughput may be less decreased. Which of the embodiments is optimal may

be determined by the balance between film quality requirements and throughput requirement.

In addition, when a titanium nitride film is formed by a high-speed CVD method, $TiCl_4$ may be supplied to the gas supply pipe **320** as well as the gas supply pipe **310** to supply the $TiCl_4$ into the processing chamber **201** both through the nozzles **410** and **420**.

By repeating formation of a titanium nitride film by a high-speed CVD method and formation of a titanium nitride film by a low-speed CVD method, a titanium nitride film, the quality of which is good like in the case where a titanium nitride film is formed by an atomic layer deposition (ALD) method, can be formed at high throughput.

In addition, by forming a titanium nitride film by a low-speed CVD method on a titanium nitride film formed by a high-speed CVD method, the under-laying high-speed CVD titanium nitride film can be modified, and thus a denser continuous film can be formed.

Furthermore, according to the current embodiment, while maintaining the productivity, the quality of a titanium nitride film can be improved, for example, by reducing the resistance and chlorine (Cl) concentration of the titanium nitride film.

In the above description, a vertical batch type apparatus has been mainly described. However, when a titanium nitride film is formed by at least two different CVD methods according to the current embodiment, instead of the vertical batch type apparatus, other apparatuses such as a horizontal apparatus and a single wafer type apparatus can be used.

Furthermore, in the above description, a vertical thermal CVD apparatus has been mainly described. However, when a titanium nitride film is formed by at least two different CVD methods according to the current embodiment, instead of the vertical thermal CVD apparatus, other apparatuses such as a plasma CVD apparatus and an optical CVD apparatus can be used.

Furthermore, although explanations have been given mainly on titanium nitride films, the present invention is not limited thereto. That is, the present invention can be applied to other kinds of films. For example, the present invention can be applied to the case where a conductive film (such as Ti, TiN, TiAlN, TiSiN, Ta, TaN, TaSiN, Al, Cu, Mn, MnO, Ru, W, GeSb, or GeSbTe film) or an insulating film (such as HfO, HfON, HfSiO, HfSiON, HfAlO, HfAlON, ZrO, AlO, or AlN film) is formed on a substrate (wafer) by using a metal halide compound or an organic metal compound as a source. In addition, for example, the present invention can be applied to the case where a Si-based film is formed on a substrate by using a Si-based halide (such as dichlorosilane (DCS) and hexachlorodisilane (HCD)) or a Si-based organic material (such as tetraethyl orthosilicate (TEOS) and tetrakis (dimethylamido)titanium (TDMAT)).

In addition, the present invention can be applied to the case of using a source including at least one of Ti, Al, Si, Ta, Cu, Mn, Ru, W, Ge, Sb, Te, Hf, and Zr. Furthermore, as a source for modifying a film including a part of a metal halide compound or a metal organic compound formed on a substrate, an O-containing source or a N-containing source may be used as well as NH_3. For example, one of N_2, N_2O, CH_6N_2, O_2, O_3, H_2O, H_2O_2, and H_2 may be used.

According to the present invention, a titanium nitride film, the quality of which is better than the quality of a titanium nitride film formed by a conventional CVD method, can be formed at a higher growth rate than the growth rate of a titanium nitride film formed by a conventional ALD method. That is, a titanium nitride film can be formed with high productivity.

[Supplementary Note]

The present invention also includes the following preferred embodiments.

(Supplementary Note 1)

According to an embodiment of the present invention, there is provided an apparatus for forming a thin film on a substrate by a reaction between two or more kinds of gases, wherein at least one of the gases is supplied into a chamber in a pulse pattern, and two or more kinds of pulses are used in a series of film forming sequences to form a thin film.

(Supplementary Note 2)

Preferably, the apparatus may be a batch type apparatus configured to process five or more substrates at a time.

(Supplementary Note 3)

Preferably, the apparatus may comprise two kinds of gas introducing units configured to supply at least one kind of gas into the chamber.

(Supplementary Note 4)

Preferably, the gas introducing units may be two or more nozzles.

(Supplementary Note 5)

Preferably, the nozzles may be multi-hole nozzles having different hole diameters.

(Supplementary Note 6)

Preferably, the thin film may be a metal compound film.

(Supplementary Note 7)

Preferably, the thin film may be a titanium nitride (TiN) film.

(Supplementary Note 8)

Preferably, the gases may comprise $TiCl_4$ and NH_3.

(Supplementary Note 9)

Preferably, $TiCl_4$ may be supplied by using the two or more kinds of pulses in the series of film forming sequences.

(Supplementary Note 10)

Preferably, the apparatus may perform a batch process to process five or more substrates at a time.

(Supplementary Note 11)

Preferably, when at least one kind of gas is supplied into the chamber, the gas may be supplied through two or more kinds of nozzles having different shapes.

(Supplementary Note 12)

Preferably, the thin film may be a metal compound film.

(Supplementary Note 13)

Preferably, the thin film may be a titanium nitride (TiN) film.

(Supplementary Note 14)

According to another embodiment of the present embodiment, there is provided a method of manufacturing a semiconductor device by simultaneously supplying two or more kinds of sources into a processing chamber to form a film on a substrate placed in the processing chamber, the method comprising: performing a first source supply process by supplying at least one kind of source into the processing chamber at a first supply flow rate; and performing a second source supply process by supplying the at least one kind of source into the processing chamber at a second supply flow rate different from the first supply flow rate.

(Supplementary Note 15)

According to another embodiment of the present invention, there is provided a method of manufacturing a semiconductor device by simultaneously supplying two or more kinds of sources into a processing chamber to form a film on a substrate placed in the processing chamber, the method comprising: performing a first film forming process to form a film on the substrate by supplying a second source into the processing chamber at a second supply flow rate while supplying a first source into the processing chamber at a first

supply flow rate; and performing a second film forming process to form a film on the substrate by supplying the second source into the processing chamber at the second supply flow rate while supplying the first source into the processing chamber at a third supply flow rate different form the first supply flow rate.

(Supplementary Note 16)

Preferably, the first film forming process and the second film forming process may be consecutively performed.

(Supplementary Note 17)

Preferably, the first film forming process and the second film forming process may be alternately performed a plurality of times.

(Supplementary Note 18)

Preferably, the third supply flow rate may be lower than the first supply flow rate.

(Supplementary Note 19)

Preferably, the third supply flow rate may be lower than the second supply flow rate.

(Supplementary Note 20)

Preferably, the first source may include at least one of Ti, Al, Si, Ta, Cu, Mn, Ru, W, Ge, Sb, Te, Hf, and Zr.

(Supplementary Note 21)

Preferably, the first source may be a halogen compound or an organic compound.

(Supplementary Note 22)

Preferably, the first source may be a halogen-containing metal compound or an organic metal compound.

(Supplementary Note 23)

Preferably, the first source may be a halogen-containing Si compound or an organic Si compound.

(Supplementary Note 24)

Preferably, the second source may an O-containing source or a N-containing source.

(Supplementary Note 25)

Preferably, the second source may be NH_3, N_2, N_2O, CH_6N_2, O_2, O_3, H_2O, H_2O_2, or H_2.

(Supplementary Note 26)

Preferably, the film may be a conductive film or an insulating film.

(Supplementary Note 27)

Preferably, the film may be one of a Ti film, a TiN film, a TiAlN film, a TiSiN film, a Ta film, a TaN film, a TaSiN film, an Al film, a Cu film, a Mn film, a MnO film, a Ru film, a W film, a GeSb film, a GeSbTe film, a HfO film, a HfON film, a HfSiO film, a HfSiON film, a HfAlO film, a HfAlON film, a ZrO film, an AlO film, a MN film, a TiO film, a SiN film, and a SiO film.

(Supplementary Note 28)

According to another embodiment of the present invention, there is provided a method of manufacturing a semiconductor device by simultaneously supplying two or more kinds of sources into a processing chamber to form a film on a substrate placed in the processing chamber, the method comprising: performing a first film forming process to form a film on the substrate by supplying a second source into the processing chamber at a second supply flow rate while supplying a first source into the processing chamber at a first supply flow rate; and performing a second film forming process to form a film on the substrate by supplying the second source into the processing chamber at a fourth supply flow rate different from the second supply flow rate while supplying the first source into the processing chamber at a third supply flow rate different form the first supply flow rate.

(Supplementary Note 29)

Preferably, the first film forming process and the second film forming process may be consecutively performed.

(Supplementary Note 30)

Preferably, the first film forming process and the second film forming process may be alternately performed a plurality of times.

(Supplementary Note 31)

Preferably, the third supply flow rate may be lower than the first supply flow rate, and the fourth supply flow rate may be higher than the second supply flow rate.

(Supplementary Note 32)

Preferably, the third supply flow rate may be lower than the fourth supply flow rate.

(Supplementary Note 33)

According to another embodiment of the present invention, there is provided a method of manufacturing a semiconductor device by simultaneously supplying two or more kinds of sources into a processing chamber to form a film on a substrate placed in the processing chamber, the method comprising: performing a first film forming process to form a film on the substrate by supplying a second source into the processing chamber at a second supply flow rate while supplying a first source into the processing chamber at a first supply flow rate; performing a second film forming process to form a film on the substrate by supplying the second source into the processing chamber at a fourth supply flow rate lower than the second supply flow rate while supplying the first source into the processing chamber at a third supply flow rate lower than the first supply flow rate; performing a third film forming process to form a film on the substrate by supplying the second source into the processing chamber at a fifth supply flow rate higher than the second supply flow rate while supplying the first source into the processing chamber at the third supply flow rate; and performing a fourth film forming process to form a film on the substrate by supplying the second source into the processing chamber at the fourth supply flow rate while supplying the first source into the processing chamber at the third supply flow rate.

(Supplementary Note 34)

According to another embodiment of the present invention, there is provided a method of manufacturing a semiconductor device by simultaneously supplying two or more kinds of sources into a processing chamber to form a film on a substrate placed in the processing chamber, the method comprising: performing a first film forming process to form a film on the substrate by supplying at least one kind of source into the processing chamber at a first supply flow rate; performing a second film forming process to form a film on the substrate by supplying the at least one kind of source into the processing chamber at a second supply flow rate different from the first supply flow rate; and performing a source removing process to remove the two or more kinds of sources from the processing chamber.

(Supplementary Note 35)

According to another embodiment of the present invention, there is provided a method of manufacturing a semiconductor device by simultaneously supplying two or more kinds of sources into a processing chamber to form a film on a substrate placed in the processing chamber, the method comprising: loading the substrate into the processing chamber; and supplying at least one kind of source into the processing chamber in a pattern of continuous pulses of two different supply flow rates.

(Supplementary Note 36)

According to another embodiment of the present invention, there is provided a substrate processing apparatus

comprising: a processing chamber configured to accommodate a substrate; a source supply unit configured to simultaneously supply a plurality of sources into the processing chamber for forming a film on the substrate; and a control unit configured to control the source supply unit for forming a film on the substrate by supplying at least one kind of source into the processing chamber at a first supply flow rate and then supplying the at least one kind of source at a second supply flow rate different from the first supply flow rate.

(Supplementary Note 37)

According to another embodiment of the present invention, there is provided a substrate processing apparatus comprising: a processing chamber configured to accommodate a substrate; a source supply unit configured to simultaneously supply a plurality of sources into the processing chamber for forming a film on the substrate; and

a control unit configured to control the source supply unit for supplying at least one kind of source into the processing chamber in a pattern of continuous pulses of two different supply flow rates.

(Supplementary Note 38)

According to another embodiment of the present invention, there is provided a semiconductor device manufactured (formed) by a semiconductor device manufacturing method in which two or more kinds of sources are simultaneously supplied into a processing chamber to form a film on a substrate placed in the processing chamber, the method comprising: performed a first source supply process by supplying at least one kind of source into the processing chamber at a first supply flow rate; and performing a second source supply process by supplying the at least one kind of source into the processing chamber at a second supply flow rate different from the first supply flow rate.

(Supplementary Note 39)

According to another embodiment of the present invention, there is provided a semiconductor device manufactured (formed) by a semiconductor device manufacturing method in which two or more kinds of sources are simultaneously supplied into a processing chamber to form a film on a substrate placed in the processing chamber, the method comprising: loading the substrate into the processing chamber; and supplying at least one kind of source into the processing chamber in a pattern of continuous pulses of two different supply flow rates.

What is claimed is:

1. A method of manufacturing a semiconductor device by simultaneously supplying a first source gas and a second source gas into a processing chamber to form a film on a substrate placed in the processing chamber, the method comprising:

(a) supplying the second source gas into the processing chamber at a second flow rate while supplying the first source gas into the processing chamber at a first flow rate to form a first film on the substrate;

(b) supplying the second source gas into the processing chamber at a fourth flow rate lower than the second flow rate while supplying the first source gas into the processing chamber at a third flow rate lower than the first flow rate to form a second film on the substrate;

(c) supplying the second source gas into the processing chamber at a fifth flow rate greater than the second flow rate while supplying the first source gas into the processing chamber at the third flow rate to form a third film on the substrate; and

(d) supplying the second source gas into the processing chamber at the fourth flow rate while supplying the first source gas into the processing chamber at the third flow rate to form a fourth film on the substrate,

wherein the step (a) through the step (d) are sequentially performed.

2. The method of claim **1**, further comprising:

(e) removing the first source gas and the second source gas from the processing chamber.

3. The method of claim **1**, wherein the film comprises one selected from a group consisting of HfO, HfON, HfSiO, HfSiON, HfAlO, HfAlON, ZrO, AlO, and AlN film.

4. The method of claim **1**, wherein the first source gas comprises at least one selected from a group consisting of Ti, Al, Si, Ta, Cu, Mu, Ru, W, Ge, Sb, Te, Hf, and Zr.

5. The method of claim **1**, wherein the second source gas comprises one selected from a group consisting of an oxygen-containing gas and a nitrogen-containing gas.

6. The method of claim **1**, wherein the second source gas comprises one selected from a group consisting of N_2, N_2O, CH_6N_2, O_2, O_3, H_2O, H_2O_2, NH_3, and H_2.
