SERVER POOL KERBEROS
AUTHENTICATION SCHEME

BACKGROUND

1. Field

The present disclosure relates to the authenticating a client against a pool of servers utilizing a secure authentication protocol, and, more specifically, to the authenticating a client against a pool of servers providing a common service, utilizing the Kerberos secure authentication protocol.

2. Background Information

Kerberos is a trusted third-party authentication protocol designed for client/server interactions. J. Kohl and B. Neuman, "*The Kerberos network authentication service (version 5)*," RFC-1510, 1993. Hereafter, a service that is substantially in compliance with the above Kerberos specification, its derivatives, or antecedents is simply referred to as "Kerberos." This includes imperfect or corrupted implementations.

A Kerberos service allows a person or client to access different machines on a network. Kerberos shares a different secret key with every entity on the network and knowledge of that secret key is considered proof of identity.

An example of a Kerberos session is illustrated in FIG. 1. A client **100** may wish to access a network service running on network server **120**. In order to do so, it must verify that it has the proper credentials to access the service utilizing the Kerberos Key Distribution Center (KDC) **110**.

Arrow **130** illustrates that in this example, when logging onto the network, the client may request a Ticket-Granting-Ticket (TGT) from the Authentication Service (AS) **113**. The client may do this by answering a challenge issued by the AS using a password. Of course, other techniques are often used and this is merely an illustrative example. Once the AS verifies that the client is a valid entity on the domain, arrow **135** illustrates that a Ticket-Granting-Ticket may be issued. This TGT is typically cached on the local machine and used to request network service sessions throughout the network.

The Ticket-Granting-Ticket usually includes two parts: a main portion of the TGT which is encrypted with a key that only the TGS **117** can decrypt, and a session key encrypted with the client's secret key. This session key is used to handle future communications with the KDC. Because the client cannot read the main portion of the TGT contents, it must blindly present the ticket to the Ticket Granting Service **117** for service tickets. In some embodiments, the TGT also includes time-to-live parameters, authorization data, or other data.

When the client **100** wishes to access a Network Service **120**, the client presents the Ticket-Granting-Ticket to the Ticket Granting Service (TGS) **117** and requests a Service Ticket, as illustrated by arrow **140**. The TGS receives the TGT and decrypts it using the TGS's secret key. The TGS determines which server provides the service the client is requesting a ticket for. The TGS then encrypts a session key with that server's secret key. This encrypted session key is incorporated into the Session Ticket. Arrow **145** illustrates that the TGS may respond to a valid request by returning a valid Service Ticket to the client.

Arrow **150** illustrates that this Service ticket may be presented to network server **120** by client **100**. The Network server may then decrypt the session key using the server's secret key. Arrow **155** illustrates that the client-server session may then be established. During each of the client-KDC and client-server transactions the various tickets may have

2

been also encrypted with the client's secret key, allowing the KDC and client to verify that the transaction was not intercepted nor involved a spoofed client or KDC.

This is merely an illustrative example of a Kerberos transaction. However, it does illustrate that the Kerberos protocol assumes that one, and only one, server provides each service. Therefore, if a service is to utilize a Kerberos protocol, it must be tied to a single server. This prevents the use of a server pool and the ability for a network to perform load balancing, among other tasks. Some techniques avoid this problem by sharing a single password among multiple servers. This technique, however, increases the manageability of the servers, for example, all server passwords must be synchronized, and decreases the security of the server pool, for example, compromising one server eases the compromising of the rest of the server pool.

BRIEF DESCRIPTION OF THE DRAWINGS

Subject matter is particularly pointed out and distinctly claimed in the concluding portions of the specification. The disclosed subject matter, however, both as to organization and the method of operation, together with objects, features and advantages thereof, may be best understood by a reference to the following detailed description when read with the accompanying drawings in which:

FIG. 1 is a block diagram illustrating an embodiment of a technique for the authenticating a client utilizing the Kerberos protocol;

FIG. 2 is a flowchart illustrating an embodiment of a technique for generating a Service Ticket to facilitate a client to authenticate against a pool of servers utilizing a secure authentication protocol in accordance with the disclosed subject matter;

FIG. 3 is a block diagram illustrating an embodiment of a Service Ticket to facilitate a client to authenticate against a pool of servers utilizing a secure authentication protocol in accordance with the disclosed subject matter;

FIG. 4 is a flowchart illustrating an embodiment of a technique for authenticating a client against a pool of servers utilizing a secure authentication protocol in accordance with the disclosed subject matter; and

FIG. 5 is a block diagram illustrating an embodiment of an apparatus and a system that allows for the authenticating a client against a pool of servers utilizing a secure authentication protocol in accordance with the disclosed subject matter.

DETAILED DESCRIPTION

In the following detailed description, numerous details are set forth in order to provide a thorough understanding of the present disclosed subject matter. However, it will be understood by those skilled in the art that the disclosed subject matter may be practiced without these specific details. In other instances, well-known methods, procedures, components, and circuits have not been described in detail so as to not obscure the disclosed subject matter.

Kerberos is a trusted third-party authentication protocol designed for client/server interactions. J. Kohl and B. Neuman, "*The Kerberos network authentication service (version 5)*," RFC-1510, 1993. Hereafter, a service that is substantially in compliance with the above Kerberos specification, its derivatives, or antecedents is simply referred to as "Kerberos." This includes imperfect or corrupted implementations.

FIG. 2 is a flowchart illustrating an embodiment of a technique for generating a Service Ticket to facilitate a client to authenticate against a pool of servers utilizing a secure authentication protocol in accordance with the disclosed subject matter. Block 210 illustrates that a Ticket Granting Service may receive a request for a Service Ticket. The Service Ticket may provide access to a client to a particular network service. In one embodiment, the Ticket Granting Service may, aside from the disclosed subject matter, substantially comply with the Kerberos protocol. It is also contemplated that the service be provided by the same machine as the requesting client. It is further contemplated that the client and server may be any physical or virtual machine including any architecture.

Block 220 illustrates that the Ticket Granting Service may determine if the requested service is provided a plurality of servers. In one embodiment, the Ticket Granting Service may utilize a Domain Name Server to determine if a generic domain name is aliased to a plurality of specific domain names. If so, the Granting Service may infer that multiple servers exist. In another embodiment, the Granting Service may refer to another database, such as, for example, a Kerberos Database, to determine if multiple servers exist. These are of course, merely a few non-limiting illustrative examples. It is contemplated that in one embodiment, the standard Kerberos database may be modified to include alias information that would facilitate the mapping of a generic server name to a plurality of specific server names.

Block 225 illustrates that, in one embodiment, if the service is provided by a single server, the Service Ticket request may be provided in single server mode. In one embodiment, the single server mode may include strict adherence to the standard Kerberos protocol. In another embodiment, the adherence to the Kerberos protocol may be less strict. It is contemplated that in yet another embodiment another technique may be used. It is also contemplated that in one embodiment, all Service Ticket requests may be processed in the same manner regardless of the number of servers utilized, and block 225 and, possibly, block 220 may not be used.

Block 230 illustrates that the Granting service may generate a random session key. Block 240 illustrates that a cipher text may be created or used. This cipher text may be encrypted with the session key. In one embodiment the cipher text may be an authenticator that includes, in one particular embodiment, the name of the client, the network address of the client, and a timestamp.

Block 260 illustrates that the session key may be encrypted with the secret key of the server providing the service. Block 250 illustrates that block 260 may be repeated for each providing server. In an illustrative embodiment, if there are, for example, 3 servers capable of providing the requested service, the Granting Service may encrypt the session key with the first server's secret key, resulting in a first encrypted session key. The session key may be encrypted with the second server's secret key, resulting in a second encrypted session key. Finally, the session key may be encrypted with the third server's secret key, resulting in a third encrypted session key. However, it is contemplated that any number of providing servers may be used and the illustrative embodiment is not meant to limit the disclosed subject matter to any particular number of providing servers.

In one embodiment, the secret keys of the providing servers may or may not be synchronized across all servers in the server pool. In another embodiment, only a portion of the providing server pool's secret keys may be synchronized. In another embodiment, sets of servers may be securely defined

with one secret key associated with each server. In one illustrative example, specific server ABC may be associated with both generic servers 123 and 789. Conversely specific server XYZ may only be associated with generic server 123. Therefore, if a client requests access to generic server 789, it would only be able to use gain access to specific server ABC, even though specific servers ABC & XYZ are pooled for generic server 123. In yet another embodiment, at least a portion of the server pool may function as a cluster server. It is also contemplated that, in some embodiments, the session key may be a one-time key.

Block 270 illustrates that a Service Ticket may be created that includes the number of providing servers, an encrypted session key for each server, and the encrypted cipher text. It is contemplated that, in one embodiment, the number of providing servers may be inherently included in the number of encrypted session keys. Therefore, in one embodiment, the Service Ticket may not include a field expressly stating the number of providing servers, but instead, may rely upon the number of encrypted session keys to provide that information. Block 280 illustrates that the Service Ticket may be transmitted, in one embodiment, to the requesting client.

FIG. 3 is a block diagram illustrating an embodiment of a Service Ticket 300 to facilitate a client to authenticate against a pool of servers utilizing a secure authentication protocol in accordance with the disclosed subject matter. The Service Ticket may include a field 310 expressly denoting the number of encrypted session keys or providing servers. A number of encrypted sessions keys may also be included, illustrated as fields 320, 330, & 380. While at least 3 encrypted session keys are illustrated in FIG. 3, it is understood that the disclosed subject matter is not limited to any number of encrypted session keys. Filed 390 may also include the encrypted cipher text. It is contemplated that the fields may be arranged in any easily determinable order and the disclosed subject matter is not limited to the arrangement illustrated. In one embodiment, the Service Ticket illustrated by FIG. 3 may have been generated in accordance with the technique illustrated in FIG. 2.

FIG. 4 is a flowchart illustrating an embodiment of a technique for authenticating a client against a pool of servers utilizing a secure authentication protocol in accordance with the disclosed subject matter. Block 410 illustrates that a providing server may receive a Service Ticket. In one embodiment, the Service Ticket may contain the fields illustrated in FIG. 3. However, other arrangements and fields are contemplated and within the scope of the disclosed subject matter.

Block 420 illustrates that the received ticket may be examined to determine if it includes encrypted session keys for multiple providing servers. If not, block 425 illustrates that the ticket may be processed in single server mode. In one embodiment, the single server mode may include strict adherence to the standard Kerberos protocol. In another embodiment, the adherence to the Kerberos protocol may be less strict. It is contemplated that in yet another embodiment another technique may be used. It is also contemplated that in one embodiment, all received Service Tickets may be processed in the same manner regardless of the number of servers utilized, and block 425 and, possibly, block 420 may not be used.

Block 430 illustrates that the number of encrypted session keys may be determined. In one embodiment the number of encrypted session keys, or servers, may be expressly noted within the Service Ticket. In another embodiment, the number of encrypted session keys may be dynamically determined by examining the Service Ticket.

5

Block 440 illustrates that the server may loop through each encrypted session key until the correct encrypted key is found. Block 445 illustrates that if the correct key is not found and error may be generated. In one embodiment, the server may silently ignore the client's request for the service. Conversely, in another embodiment, the server may report the unsuccessful access attempt to, for example, the client, or an agent that monitors the network security. However, other responses are contemplated and these are just a few non-limiting examples.

In one embodiment, the server may not need to enumerate through the encrypted session keys. For example, each encrypted key may be paired with a particular server identifier field. The server identifier field may express denote which encrypted session key utilizes the secret key of the receiving server. In one embodiment, the server identifying field may denote the Internet Protocol number of each server. The receiving server may then go directly to the encrypted session key associated with the receiving server's Internet Protocol number. As a result, block 440 would not be needed. In other embodiments, other techniques for determining which encrypted session key is associated with the receiving server may be used.

Block 450 illustrates that the server may attempt to decrypt the current encrypted session key with the server's secret key. Block 460 illustrates that an attempt to decrypt the cipher text may then be made utilizing the decrypted session key. If the session key was successfully decrypted, the cipher text should be successfully decrypted as well. If the session key was not encrypted with the receiving server's secret key, it will not successfully decrypt and the cipher text will also not successfully decrypt.

Block 470 illustrates that the server may determine if the cipher text was successfully decrypted. If not, the server will loop back to block 440 and attempt to decrypt the next encrypted session key, if any exist. If so, block 480 illustrates that client has gained access to the requested service and that the requested client-server transaction may continue.

FIG. 5 is a block diagram illustrating an embodiment of an apparatus 501 and a system 500 that allows for the authenticating a client against a pool of servers 550 utilizing a secure authentication protocol in accordance with the disclosed subject matter. In one embodiment, apparatus 501 may include a Key Distribution Center (KDC) 510 capable of generating a multi-server service ticket 540. In one embodiment, the KDC may be, aside from the capability to generate the multi-server service ticket, substantially in compliance with the Kerberos protocol.

Key Distribution Center (KDC) 510 may include an Authentication Service (AS) 520 and a Ticket Granting Service (TGS) 530. The AS may be capable of authenticating that a client 590 is legitimately accessing the KDC and/or the network domain and be capable of issuing a Ticket-Granting-Ticket to the client. In one embodiment, the AS these capabilities may be provided substantially in compliance with the Kerberos protocol. The TGS may be capable of receiving a request for a Service Ticket and issue a multi-server service ticket 540. In one embodiment, the TGS may be capable of performing the technique illustrated by FIG. 2. In one embodiment, the Multi-Server Service Ticket may include the fields illustrated by FIG. 3. In one embodiment, the request for a Service Ticket may include or utilize the Ticket-Granting-Ticket issued by the AS.

System 500 may include the apparatus 501 and a pool of servers 550. The pool of servers may be capable of receiving and utilizing a multi-server service ticket 540. In one

6

embodiment, the servers in the pool may be capable of performing the technique illustrated in FIG. 4. It is contemplated that while FIG. 5 shows three network servers 553, 555, & 559 in the server pool, the disclosed subject matter is not limited to any particular number of servers. It is contemplated that in a unique embodiment, only one server may exist in the pool at a particular time.

In an illustrative example, client 590 may authenticate itself on the network utilizing the Key Distribution Center (KDC) 510, and in particular, the Authentication Server (AS) 510. The client may receive a Ticket-Granting-Ticket (TGT). The client may use this TGI to request a Service Ticket from the Ticket Granting Service (TGS) 530. The TGS may determine that the service is provided by a server pool 550, and issue a Multi-Server Service Ticket 540. The client may present this Service Ticket to the server pool. The Second Network Server 555 may be selected by the manager of the server pool to process the client's request. The Second Network Server may authenticate the client's ability to receive the service and provide the service to the client. It is understood that the above example is merely one possible embodiment of the use of the apparatus 501 and system 500 and other uses are possible and contemplated.

It is also contemplated that the disclosed subject matter is not limited to any particular computing platform. While FIG. 5 utilizes representations of traditional personal computers the disclosed subject matter is not limited to any particular architecture and may include devices, such as, for example, a laptop computer, a handheld computer, a personal digital assistant, a wireless local area network (WLAN) device, and a computer peripheral, such as, for example, a printer or mouse. However, these are merely a few non-limiting examples of such a device.

The techniques described herein are not limited to any particular hardware or software configuration; they may find applicability in any computing or processing environment. The techniques may be implemented in hardware, software, firmware or a combination thereof. The techniques may be implemented in programs executing on programmable machines such as mobile or stationary computers, personal digital assistants, and similar devices that each include a processor, a storage medium readable or accessible by the processor (including volatile and non-volatile memory and/or storage elements), at least one input device, and one or more output devices. Program code is applied to the data entered using the input device to perform the functions described and to generate output information. The output information may be applied to one or more output devices.

Each program may be implemented in a high level procedural or object oriented programming language to communicate with a processing system. However, programs may be implemented in assembly or machine language, if desired. In any case, the language may be compiled or interpreted.

Each such program may be stored on a storage medium or device, e.g. compact read only memory (CD-ROM), digital versatile disk (DVD), hard disk, firmware, non-volatile memory, magnetic disk or similar medium or device, that is readable by a general or special purpose programmable machine for configuring and operating the machine when the storage medium or device is read by the computer to perform the procedures described herein. The system may also be considered to be implemented as a machine-readable or accessible storage medium, configured with a program, where the storage medium so configured causes a machine to operate in a specific manner. Other embodiments are within the scope of the following claims.

While certain features of the disclosed subject matter have been illustrated and described herein, many modifications, substitutions, changes, and equivalents will now occur to those skilled in the art. It is, therefore, to be understood that the appended claims are intended to cover all such modifications and changes that fall within the true spirit of the disclosed subject matter.

What is claimed is:

1. A method of generating a Service Ticket for a requested network service, comprising:

receiving, by a granting computing device, the granting computing device being different and distinct from a client computing device, a request for a Service Ticket for a requested network service from the client computing device;

in response to receiving the request for the Service Ticket from the client computing device, querying, by the granting computing device, a database that indicates which of one or more servers provides the requested network service;

determining, by the granting computing device based on the querying, that the requested network service is provided by a server pool comprising a plurality of servers, the plurality servers being to allow access by the client computing device to the requested network service only when presented with the Service Ticket and only when the Service Ticket includes a session key;

generating, by the granting computing device, the session key, to facilitate access of the requested network service by the client computing device to the plurality of servers;

for each respective server of the plurality of servers of the server pool, encrypting, by the granting computing device, a copy of the session key with a respective secret key associated with a respective one of the plurality of the servers of the server pool to create a set of respective encrypted session keys, wherein each respective encrypted session key in the set of respective encrypted session keys corresponds to one of the respective servers of the server pool;

creating, by the granting computing device, the Service Ticket that includes the set of respective encrypted session keys; and

transmitting, by the granting computing device, the created Service Ticket to the client computing device to allow the client computing device to access the requested network service at the plurality of servers, the access by the client computing device including provision, by the client computing device to one or more of the plurality of servers of the server pool, of the Service Ticket to access the requested network service.

2. The method of claim 1, further comprising:

generating, by the granting computing device, a Ticket-Granting-Ticket in compliance with the Kerberos protocol;

wherein receiving, by the granting computing device, the request for the Service Ticket from the client computing device includes the granting computing device receiving the Ticket-Granting-Ticket from the client computing device.

3. The method of claim 1, wherein the method further comprises, after determining, by the granting computing device, that the requested network service is provided by the server pool:

determining, by the granting computing device, a number of the plurality of servers of the server pool designated to provide the requested network service; and
encrypting, by the granting computing device, a cipher text with the session key;

wherein querying the database that indicates which of one or more servers provides the requested network service includes:

utilizing, by the granting computing device, a database that maps generic server names to specific server names, and

setting, by the granting computing device, the numbers of servers designated to provide the network service equal to a number of specific server names mapped to a generic server name that provides the requested network service.

4. The method of claim 3, wherein the database that maps generic server names to specific server names is selected from a group consisting essentially of:

a domain name server database,
a database associated with a Key Distribution Center, and
a Kerberos database.

5. The method of claim 1, wherein the respective secret keys associated with respective providing servers of the server pool are not synchronized across the respective providing servers.

6. The method of claim 3, wherein the created Service Ticket includes:

(1) a header that designates the Service Ticket as a format that includes multiple respective encrypted session keys,

(2) a field that expressly designates the number of respective encrypted session keys,

(3) the set of respective encrypted session keys, and

(4) the cipher text.

7. One or more non-transitory computer readable media having instructions thereon that, when executed by one or more processing devices of a computing device, cause the computing device to:

receive a request for a Service Ticket for a requested network service from a client computing device, the client computing device being different and distinct from the computing device;

in response to reception of the request for the Service Ticket from the client computing device, query a database that indicates which of one or more servers provides the requested network service;

determine, based on the query, that the requested network service is provided by a server pool comprising a plurality of servers, the plurality of servers being to allow access by the client computing device to the requested network service only when presented with the Service Ticket and only when the Service Ticket includes a session key;

generate the session key to facilitate access of the requested network service by the client computing device to the plurality of servers;

for each respective server of the plurality of servers of the server pool, encrypt a copy of the session key with a respective secret key associated with a respective one of the plurality of servers of the server pool to create a set of respective encrypted session keys, wherein each respective encrypted session key in the set of respective encrypted session keys corresponds to one of the respective servers of the server pool;

create the Service Ticket that includes each of the set of respective encrypted session keys; and

9

transmit the created Service Ticket to the client computing device to allow the client computing device to access the requested network service at the plurality of servers, the access by the client computing device including provision, by the client computing device to one or more of the plurality of servers of the server pool, of the Service Ticket to access the requested network service.

8. The one or more computer readable media of claim 7, further comprising instructions thereon that, when executed by the one or more processing devices of the computing device, cause the computing device to:

generate a Ticket-Granting-Ticket in compliance with a Kerberos protocol;

wherein receive the request for the Service Ticket from the client computing device includes receive the Ticket-Granting-Ticket from the client computing device.

9. The one or more computer readable media of claim 7, further comprising instructions thereon that, when executed by the one or more processing devices of the computing device, cause the computing device to, after determination that the requested network service is provided by a server pool:

determine a number of the plurality of servers of the server pool designated to provide the requested network service; and

encrypt a cipher text with the session key;

wherein query the database that indicates which of one or more servers provides the requested network service includes:

10

utilize a database that maps generic server names to specific server names, and

set the numbers of servers designated to provide the requested network service equal to a number of specific server names mapped to a generic server name that provides the requested network service.

10. The one or more computer readable media of claim 9, wherein the database that maps generic server names to specific server names is selected from a group consisting essentially of:

a domain name server database,

a database associated with a Key Distribution Center, and a Kerberos database.

11. The one or more computer readable media of claim 9, wherein the created Service Ticket includes:

(1) a header that designates the Service Ticket as a format that includes multiple respective encrypted session keys,

(2) a field that expressly designates a number of respective encrypted session keys,

(3) the set of respective encrypted session keys, and

(4) the cipher text.

12. The one or more computer readable media of claim 7, wherein the respective secret keys associated with respective providing servers are not synchronized across the respective providing servers.
