FIG. 1

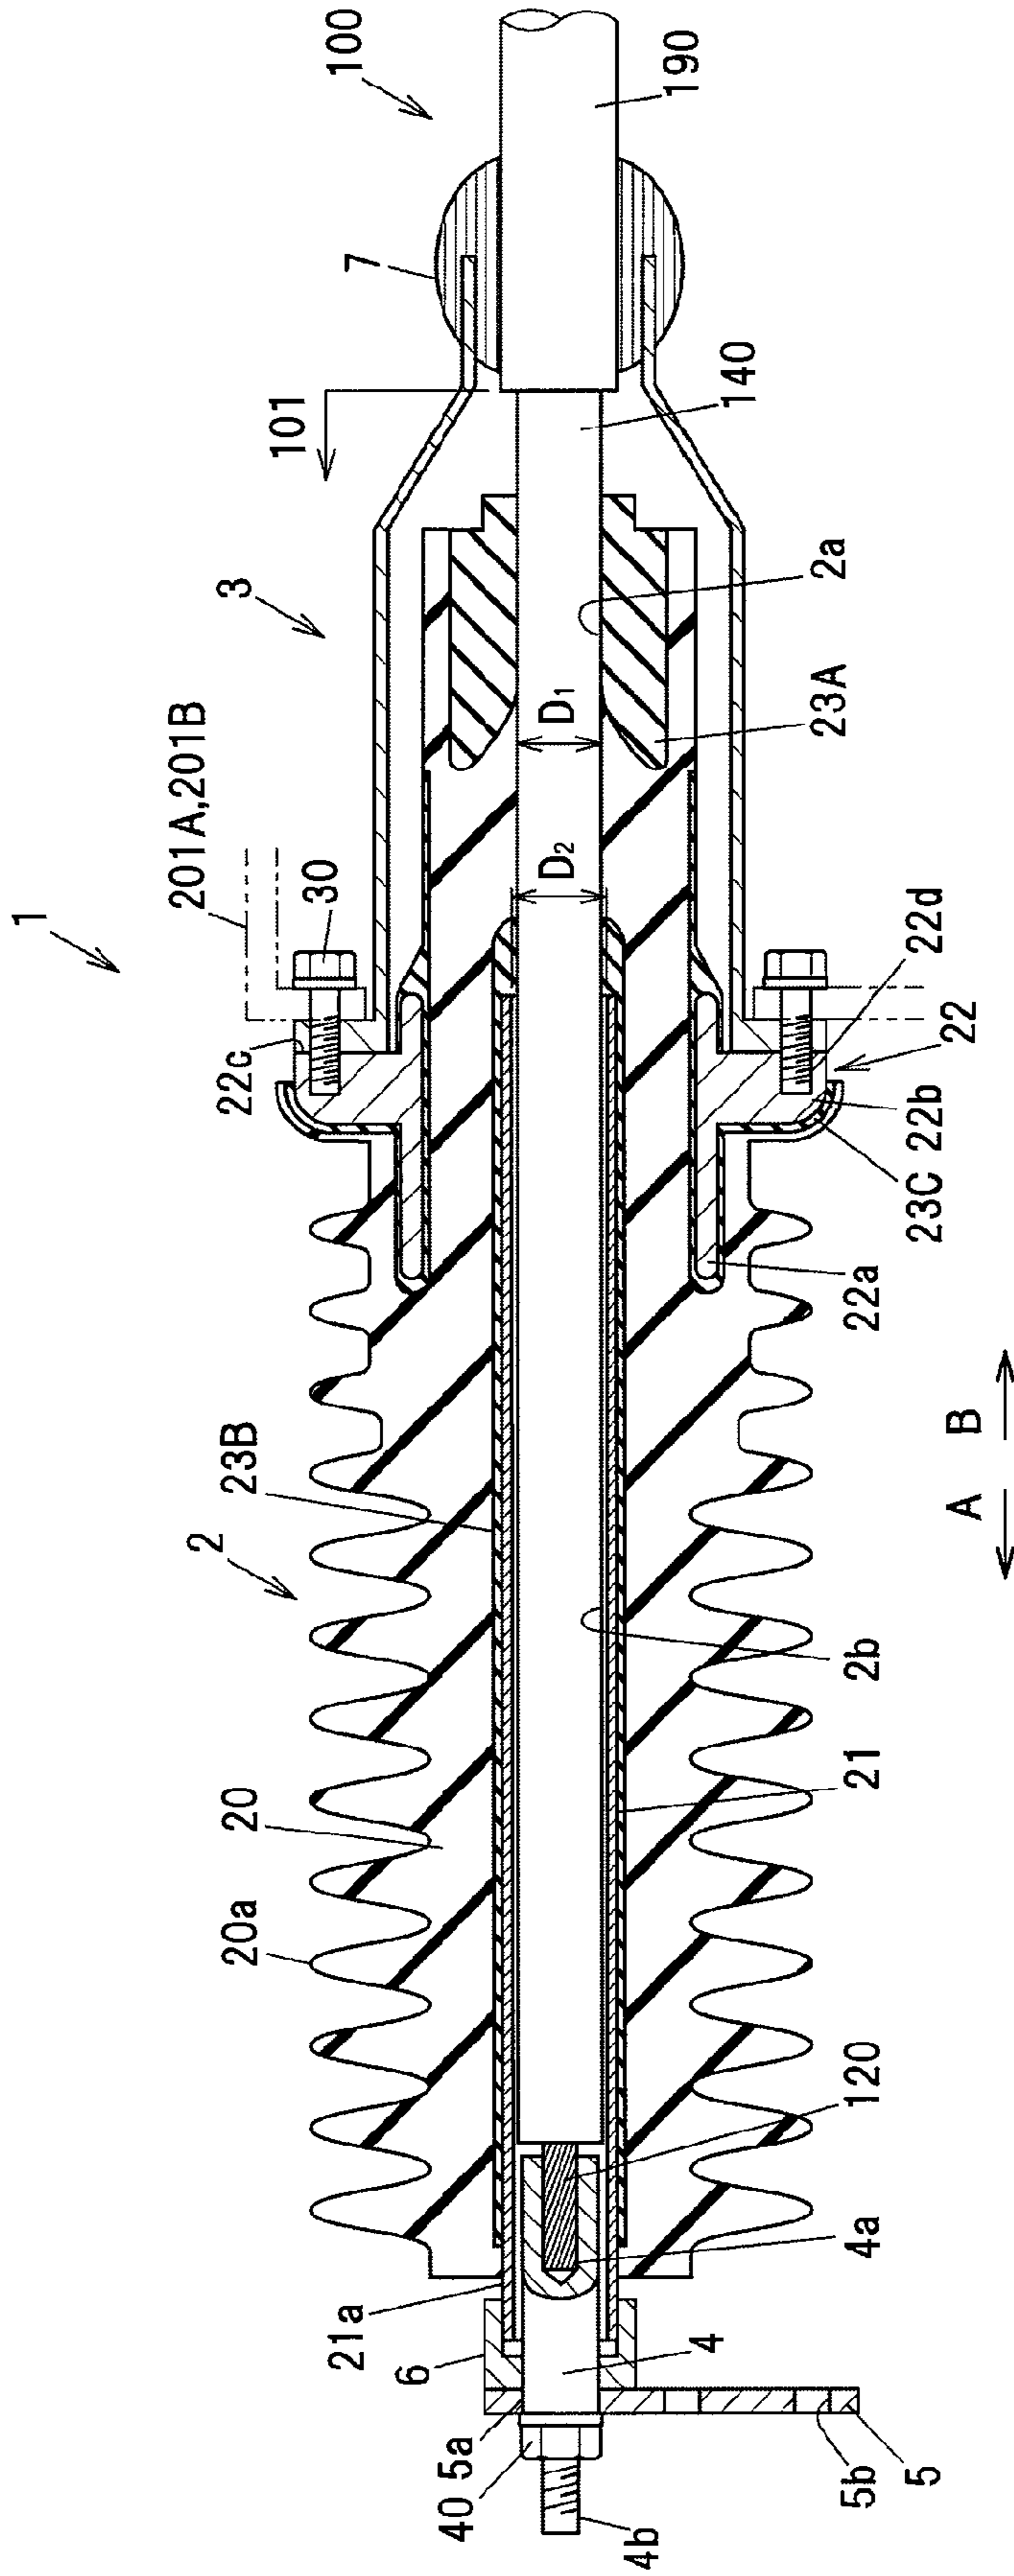

FIG. 2

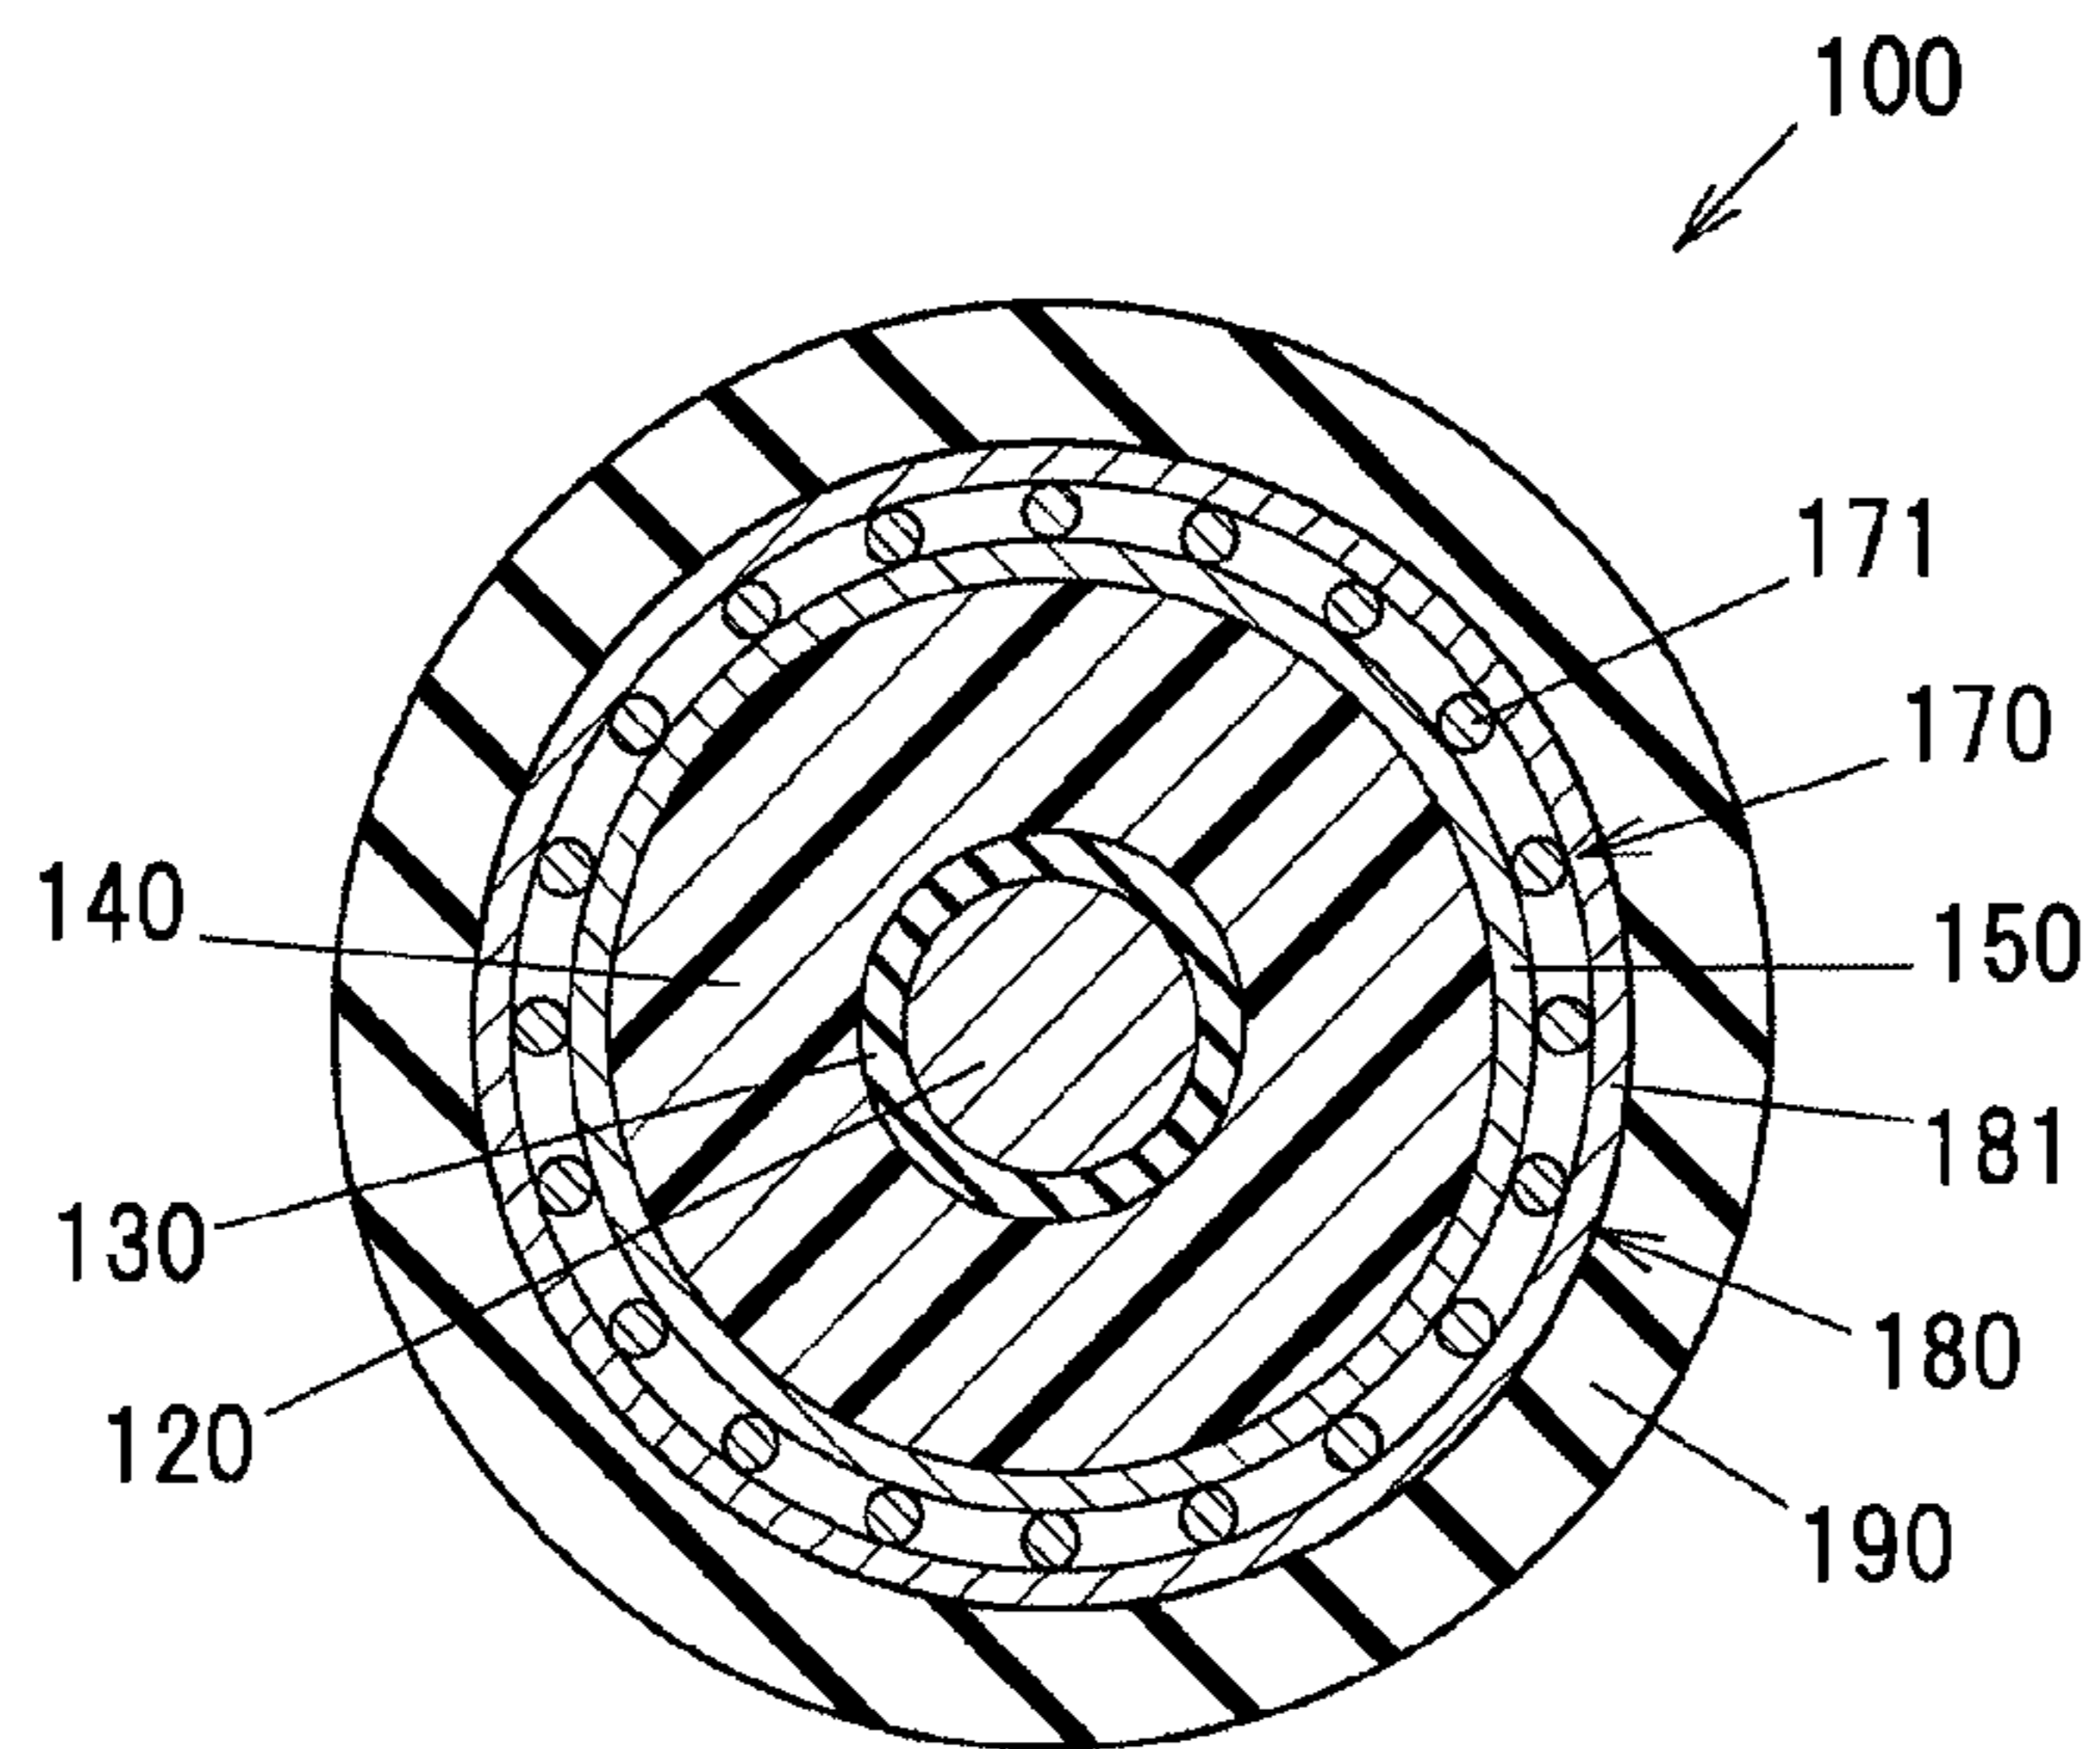

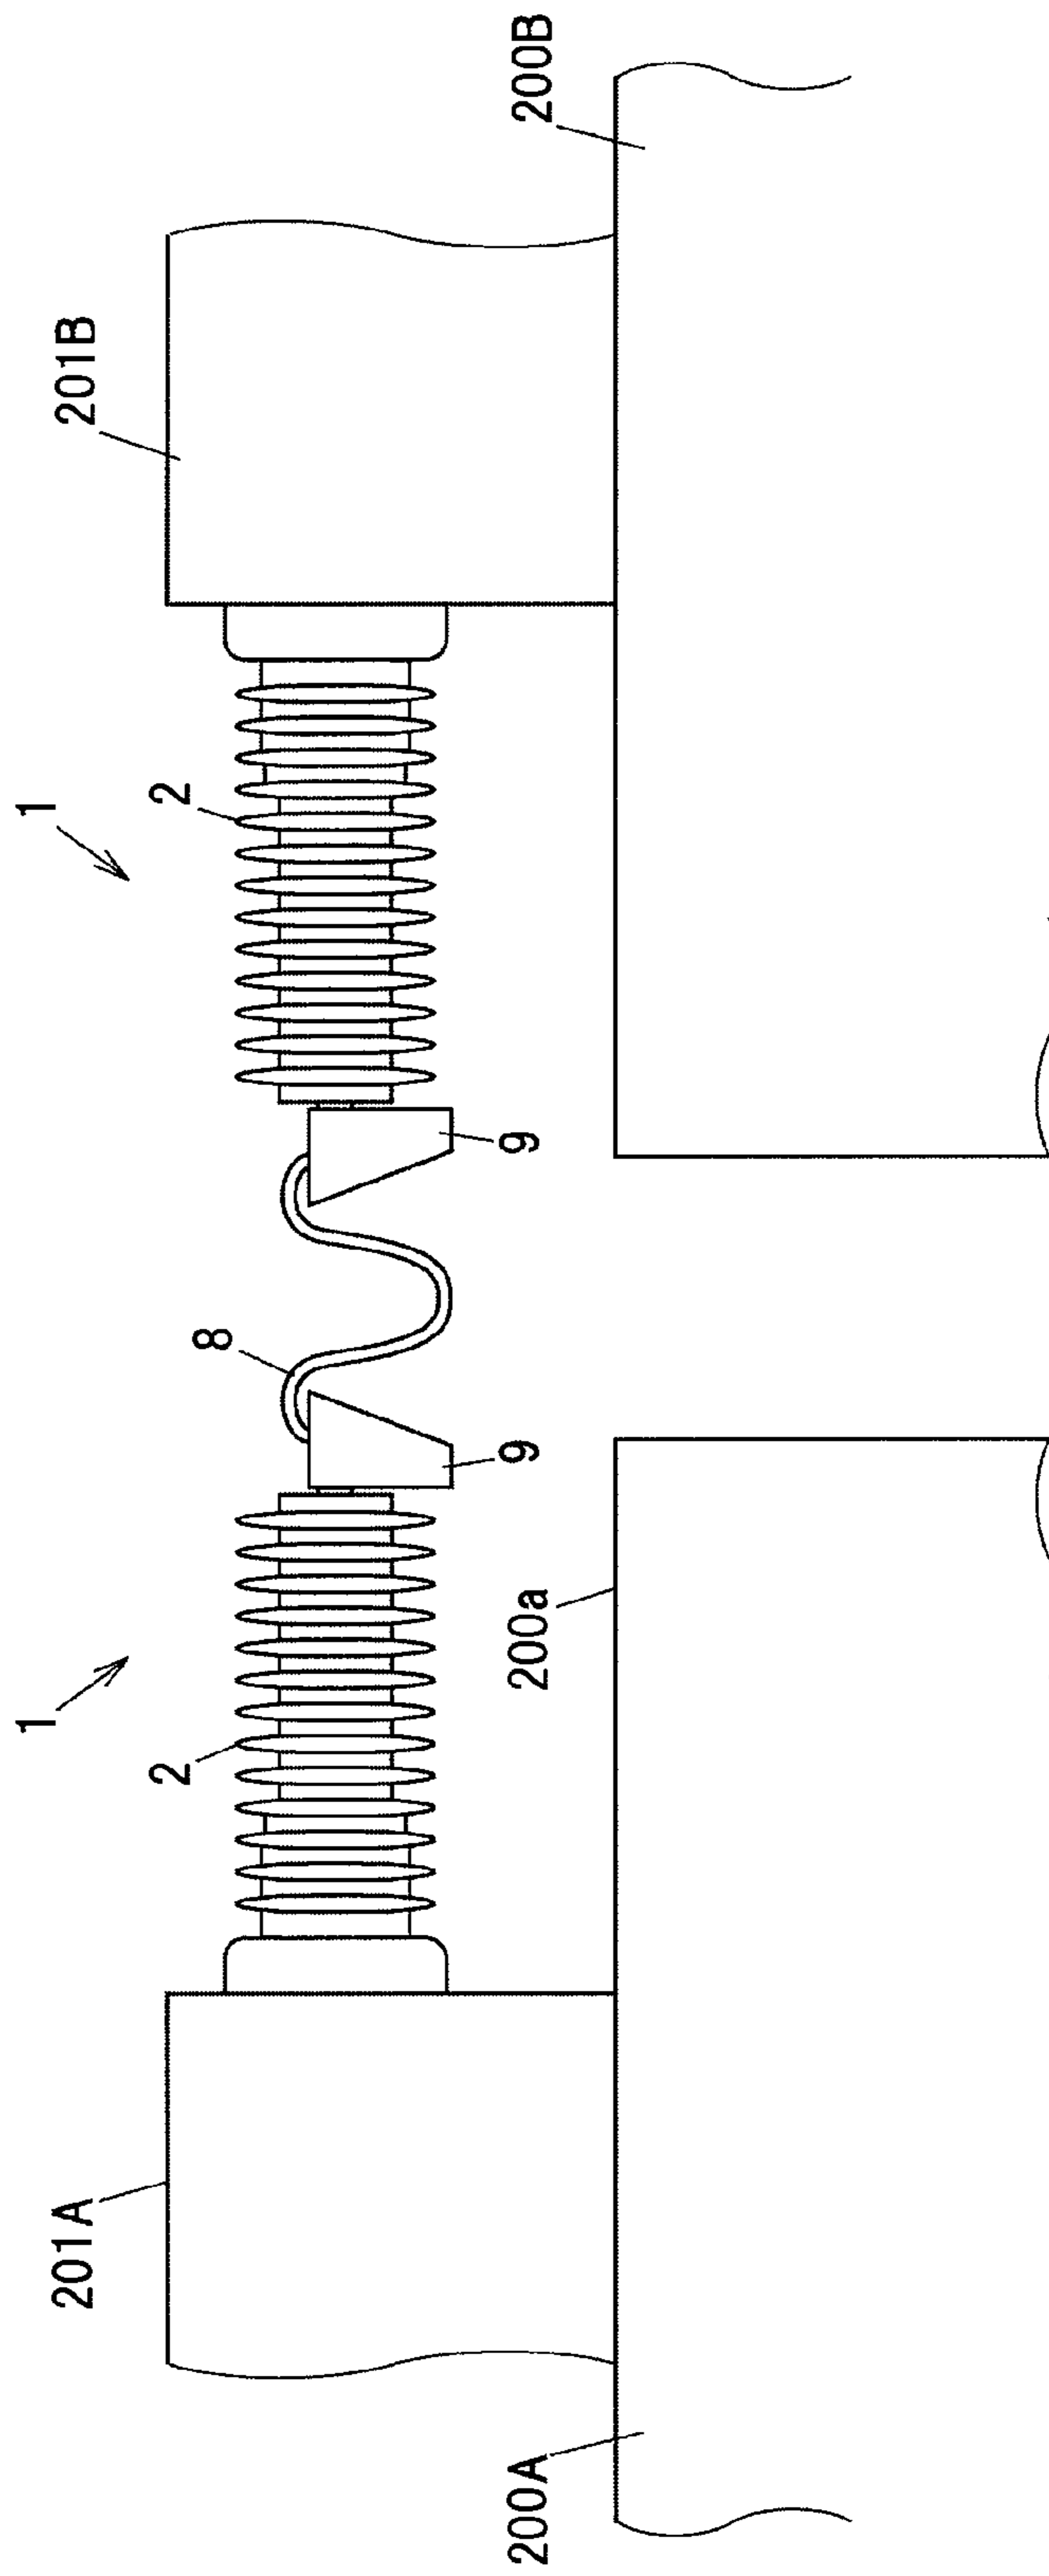

FIG. 3

1

POWER CABLE POLYMER CONNECTOR

TECHNICAL FIELD

The present invention relates to a power cable polymer connector using a polymeric insulating tube.

BACKGROUND ART

Since conventional porcelain insulator-type freestanding dry terminal connectors have a relatively heavy porcelain insulator, a freestanding dry terminal connector lighter than the porcelain insulator has been proposed (see e.g., PTL 1).

The freestanding dry terminal connector is composed of a flexible rubber insulation layer having cable insertion holes for insertion of an end side of a cable, and a freestanding resin tube which is integrally provided in the insulation layer in the middle of the thickness of the insulation layer so as to extend in an axial direction and has electrical insulating properties and rigidity.

By the above composition, the weight of the terminal connector can be reduced by using the light rubber insulation layer and the resin tube as a core. Also, the free-standing property to maintain a vertical upright position can be exerted by using the resin tube as the core. Thus, the installation on utility poles can be facilitated.

CITATION LIST

Patent Literature

[PTL 1]
JP-B-5060800

SUMMARY OF INVENTION

Technical Problem

The conventional freestanding dry terminal connectors, however, have the freestanding resin tube as the core formed of the resin, so that if the connectors are used horizontally it is difficult for them to maintain the horizontal position by itself and the tip portion thereof may hang down. Thus, the resin tube is not good enough for the core.

It is an object of the invention to provide a power cable polymer connector that has a lighter weight than the porcelain insulator and exerts the free-standing property to maintain a horizontal position even if it is used horizontally.

Solution to Problem

To solve the problems mentioned above, the present invention provides a power cable polymer connector comprising a polymeric insulating tube comprising a cable insertion hole to allow an insertion of an end of a power cable,

wherein the polymeric insulating tube further comprises an insulation comprising a polymer-based material and an embedded pipe comprising a metal and embedded on an inner peripheral surface of the insulation so as to face the end of the power cable.

The embedded pipe preferably comprises an outer peripheral surface not more than 6.3 μm in an arithmetic mean roughness Ra.

Advantageous Effects of Invention

According to the present invention, a power cable polymer connector can have a lighter weight than the porcelain

2

insulator and exert the free-standing property to maintain the horizontal position even if it is used horizontally.

BRIEF DESCRIPTION OF DRAWINGS

FIG. 1 is a longitudinal-sectional view showing a configuration example of a power cable polymer connector in a first embodiment of the present invention.

FIG. 2 is a cross-sectional view showing a power cable shown in FIG. 1.

FIG. 3 is a front view showing a main portion of a configuration example of vehicle-to-vehicle connector in a second embodiment of the invention.

DESCRIPTION OF EMBODIMENTS

Embodiments of the invention will be described below in reference to the drawings. Constituent elements having substantially the same functions are denoted by the same reference numerals in each drawing and the overlapping explanation thereof will be omitted.

First Embodiment

FIG. 1 is a longitudinal-sectional view showing a configuration example of a power cable polymer connector in the first embodiment of the invention. FIG. 2 is a cross-sectional view showing a power cable shown in FIG. 1.

A power cable polymer connector **1** is formed mainly of a polymer-based material (an insulating polymer material), and is provided with a polymeric insulating tube **2** having cable insertion holes **2a** and **2b** for insertion of a stripped end **101** of a power cable **100**, a protective metal fitting **3** for protecting a rear-end side B (opposite to an insertion direction A) of the polymeric insulating tube **2**, a conductor-connecting rod **4** connected to a conductor **120** of the power cable **100**, a fixing terminal **5** to which the conductor-connecting rod **4** is attached, a high-pressure shield **6** connected to the conductor-connecting rod **4** via the fixing terminal **5**, and a waterproofing portion **7** for sealing between the protective metal fitting **3** and the power cable **100**.

Configuration of Polymeric Insulating Tube

The polymeric insulating tube **2** is provided with a flexible insulation **20** formed of a polymer-based material, an embedded pipe **21** as a reinforcing member or a core formed of a metal and embedded on an inner peripheral surface of the insulation **20** so as to face an insulation layer **140** of the end **101** of the power cable **100**, an embedded flange **22** as a reinforcing member or a core formed of a metal and embedded in the insulation **20** on the outer peripheral side, a first semi-conductive portion **23A** for relaxing an electric field at the end **101** of the power cable **100**, a second semi-conductive portion **23B** for relaxing an electric field in the embedded pipe **21**, and a third semi-conductive portion **23C** for relaxing an electric field in the embedded flange **22**. The insulation **20**, the embedded pipe **21**, the embedded flange **22** and the first to third semi-conductive portions **23A** to **23C**, which constitute the polymeric insulating tube **2**, are integrally formed using a mold in a factory. The insulation **20** and the first to third semi-conductive portions **23A** to **23C** here are an example of insulation protective layer.

Plural umbrella portions **20a** are formed on the outer periphery of the insulation **20** at certain intervals. The

3

polymer-based material for forming the insulation **20** is, e.g., a silicone rubber, an ethylene-propylene rubber (EPM) or an ethylene-propylene-diene rubber (EPDM), etc.

The first cable insertion hole **2a** of the insulation protective layer located on the side B opposite to the insertion direction A has a smaller inner diameter than an outer diameter D_1 of the end **101** of the power cable **100**, i.e., of the insulation layer **140**, before insertion of the end **101** of the power cable **100**, and is tightly in contact with the insulation layer **140** once the insulation layer **140** of the power cable **100** is inserted.

The embedded pipe **21** is formed of, e.g., a metal such as brass or aluminum alloy. The embedded pipe **21** has, e.g., an outer diameter of 30 to 50 mm and a thickness of 2 to 5 mm. To facilitate insertion of the power cable **100**, the embedded pipe **21** has the second cable insertion hole **2b** having an inner diameter D_2 which is larger than the outer diameter of the insulation layer **140**. Since the outer peripheral surface of the embedded pipe **21** is covered with the second semi-conductive portion **23B**, it is possible to use a commercially available product as the embedded pipe **21**. Alternatively, the second semi-conductive portion **23B** can be omitted when the embedded pipe **21** is formed to have a smooth outer peripheral surface (e.g., with an arithmetic mean roughness Ra of not more than 6.3 μm).

The embedded pipe **21** also has a portion **21a** which is located at an end portion in the insertion direction A and is exposed from the insulation **20** in an axial direction of the cable. The exposed portion **21a** is connected to the high-pressure shield **6** as a connecting member, and the high-pressure shield **6** is connected to the conductor **120** of the power cable **100** via the fixing terminal **5** and the conductor-connecting rod **4**. As a result, the embedded pipe **21** exerts a shielding effect. That is, in case of a structure in which the embedded pipe **21** is not embedded on the inner peripheral surface of the insulation **20**, a space between the inner peripheral surface and the insulation layer **140** of the power cable **100** needs to be filled with an insulating compound to prevent insulation breakdown. On the other hand, in the present embodiment, since the embedded pipe **21** is embedded on the inner peripheral surface of the insulation **20** and is connected to the conductor **120** of the power cable **100**, a space between the embedded pipe **21** and the insulation layer **140** is a close space and there is no need to fill a compound between the embedded pipe **21** and the insulation layer **140**.

The embedded flange **22** is provided with a cylinder portion **22a** having a cylindrical shape and a flange portion **22b** provided on the outer peripheral surface of the cylinder portion **22a** all around the circumference. The embedded flange **22** is embedded in the insulation **20** on the outer peripheral side so that a mounting surface **22c** to be attached to another member is exposed from the insulation **20**. Female screws **22d** are formed on the mounting surface **22c** so that the embedded flange **22** can be attached to a case, etc., by bolts **30**. The embedded flange **22** having such a configuration is formed of, e.g., a metal such as brass or aluminum alloy and is connected to a ground when in use.

The first to third semi-conductive portions **23A** to **23C** are formed mainly of a polymer-based material. In detail, the first to third semi-conductive portions **23A** to **23C** are formed by extruding a polymer-based material which is obtained by, e.g., dispersing conductive powder such as carbon in a silicone rubber, EMP or EPDM, etc., and thus has conductivity.

The first semi-conductive portion **23A**, before insertion of the end **101** of the power cable **100**, has a smaller outer

4

diameter than the outer diameter D_1 of the insulation layer **140**. The second semi-conductive portion **23B** covers the outer peripheral surface of the embedded pipe **21** except an end portion on the insertion direction A side. The third semi-conductive portion **23C** covers a surface of the embedded flange **22** which is not exposed from the insulation **20**.

Other Configuration

The protective metal fitting **3** is formed of, e.g., a metal such as brass or aluminum alloy and is configured to allow the power cable polymer connector **1** to be attached to a case **201A** or **201B** (described later) by the bolts **30**.

The conductor-connecting rod **4** has a connection hole **4a** formed on the rear-end side and a male screw **4b** formed on the front-end side. After inserting the conductor **120** of the power cable **100** into the connection hole **4a** of the conductor-connecting rod **4**, the diameter of the connection hole **4a** is reduced by crimping the rear-end side of the conductor-connecting rod **4** and the conductor-connecting rod **4** is thereby connected to the conductor **120** of the power cable **100**.

The fixing terminal **5** has an insertion hole **5a** for inserting the conductor-connecting rod **4** and a connection hole **5b** to which an electric wire is connected. The conductor-connecting rod **4** is inserted into the insertion hole **5a**, the male screw **4b** is tightened with a nut **40**, and the fixing terminal **5** is thereby attached to the conductor-connecting rod **4**.

The high-pressure shield **6** is formed of a metal and has a cylindrical shape surrounding the conductor-connecting rod **4**. The high-pressure shield **6** connects the embedded pipe **21** to the fixing terminal **5** and the conductor-connecting rod **4** is thereby shielded.

The waterproofing portion **7** is formed by winding a highly waterproof member, e.g., a polyethylene tape or epoxy tape, etc., having an adhesive layer.

Configuration of Power Cable

The power cable **100** is composed of the conductor **120** formed of a twisted wire, an inner semi-conductive layer **130** formed around the conductor **120**, the insulation layer **140** formed around the inner semi-conductive layer **130**, an outer semi-conductive layer **150** formed around the insulation layer **140**, a shield layer **170** formed by winding wires **171** around the outer semi-conductive layer **150**, a binding tape layer **180** formed by winding a binding tape **181** around the shield layer **170**, and a sheath layer **190** formed around the binding tape layer **180**.

The conductor **120** is formed by twisting plural strands together. As the strand, it is possible to use a wire rod, e.g., a tin-plated soft copper wire, etc. The conductor **120** transmits electricity with a high voltage of, e.g., not less than 7000V.

The inner semi-conductive layer **130** and the outer semi-conductive layer **150** are provided to relax electric field concentration, is formed mainly of a polymer-based material, and is formed by extruding a material which is obtained by, e.g., dispersing conductive powder such as carbon in a rubber such as ethylene-propylene rubber, ethylene-vinyl acetate copolymer (EVA) resin or butyl rubber and thus has conductivity.

The insulation layer **140** is formed by extruding a material such as ethylene-propylene rubber, vinyl chloride, cross-linked polyethylene, silicone rubber or fluorine-based material, etc.

5

The shield layer **170** is formed by spirally winding the wires **171** around the outer semi-conductive layer **150** along the axial direction of the cable. The shield layer **170** is connected to a ground when in use.

The binding tape layer **180** is formed by spirally winding the binding tape **181**, with an overlap, around the shield layer **170** along the axial direction of the cable. The binding tape **181** used can be, e.g., a plastic or rayon tape having a thickness of 0.03 to 0.5 mm and a width of 50 to 90 mm.

The sheath layer **190** is formed by extruding a material formed by adding a cross-linking agent, etc., to a rubber such as natural rubber, butyl rubber, halogenated butyl rubber, ethylene-propylene rubber, chloroprene rubber, styrene-butadiene rubber, nitrile rubber, chlorosulfonated polyethylene, chlorinated polyethylene, epichlorohydrin rubber, acrylic rubber, silicone rubber, fluoro-rubber, urethane rubber or halogen-free polyolefin elastomer.

Functions and Effects of the First Embodiment

In the first embodiment, the following functions and effects are obtained.

(1) Since a polymer-based material, which is lighter than porcelain, is used as the insulation and also the thin embedded pipe **21** is used as a reinforcing member, the power cable polymer connector **1** of the invention is lighter than when using a porcelain insulator.

(2) The embedded pipe **21** formed of a metal is embedded on the inner peripheral surface of the insulation **20**. Therefore, even when used horizontally, the power cable polymer connector **1** of the invention exerts the free-standing property and can maintain the horizontal position.

(3) In addition to the embedded pipe **21**, the embedded flange **22** formed of a metal is also embedded in the insulation **20** on the outer peripheral side. Therefore, even when used horizontally, the power cable polymer connector **1** of the invention exerts the free-standing property and can maintain the horizontal position.

(4) The outer peripheral surface of the embedded pipe **21** is covered with the second semi-conductive portion **23B**. Therefore, even if the embedded pipe **21** has a flaw on the outer peripheral surface, electric field concentration due to the flaw can be relaxed.

(5) The surface of the embedded flange **22**, except a portion exposed from the insulation **20**, is covered with the third semi-conductive portion **23C**. Therefore, even if the embedded flange **22** has a flaw on the surface, electric field concentration due to the flaw can be relaxed.

(6) Since the embedded pipe **21** is connected to the conductor **120** of the power cable **100**, a space between the embedded pipe **21** and the insulation layer **140** is a close space and there is no need to fill a compound between the embedded pipe **21** and the insulation layer **140**.

Second Embodiment

FIG. 3 is a front view showing a main portion of an example of vehicle-to-vehicle connector in the second embodiment of the invention. The vehicle-to-vehicle connector, to which the power cable polymer connector in the first embodiment is applied, includes a power cable polymer connector **1A** attached to the case **201A** provided on a roof of a railway vehicle **200A** on one side, a power cable polymer connector **1B** attached to the case **201B** provided on a roof of a railway vehicle **200B** on the other side, a flexible electric wire **8** for connecting the two power cable polymer connectors **1A** and **1B**, and insulation covers **9**

6

covering the conductor-connecting portions **4**, the fixing terminals **5** and the high-pressure shields **6** of the power cable polymer connectors **1A** and **1B**.

To attach the power cable polymer connectors **1A** and **1B** to the cases **201A** and **201B**, the bolts **30** are screwed into the female screws **22d** of the embedded flange **22** and tightened with the protective metal fitting **3** in-between, as shown in FIG. 1.

The power cable polymer connectors **1A** and **1B** are connected to each other by attaching a conductor of the electric wire **8** to the respective fixing terminals **5**.

Functions and Effects of the Second Embodiment

In the second embodiment, the following functions and effects are obtained.

(1) In the power cable polymer connectors **1A** and **1B**, the embedded pipe **21** formed of a metal is embedded on the inner peripheral surface of the insulation **20** and also the embedded flange **22** formed of a metal is embedded in the insulation **20** on the outer peripheral side. Therefore, the power cable polymer connectors **1A** and **1B** hardly hang down on the tip side even when positioned horizontally and this allows the power cable polymer connectors **1A** and **1B** to be used in a horizontal position.

(2) The power cable polymer connectors **1A** and **1B** are connected to each other by the flexible electric wire **8**. Therefore, even when the railway vehicles **200A** and **200B** turn a curve, it is possible to follow the curve.

The present invention is not intended to be limited to the above-mentioned embodiments, and the various kinds of embodiments can be implemented. For example, although the cable terminal connector has been described in each embodiment, the invention is also applicable to a cable intermediate connector.

In addition, although horizontal use has been described in the second embodiment, the invention is also applicable to vertical use.

In addition, some of the constituent elements in the above-mentioned embodiments can be omitted or changed without changing the gist of the invention. For example, in the above-mentioned embodiments, the second semi-conductive portion **23B** may be omitted when forming the embedded pipe **21** to have a smooth or mirror outer peripheral surface. Also, in the above-mentioned embodiments, the third semi-conductive portion **23C** may be omitted when forming the embedded flange **22** to have a smooth or mirror surface.

The invention claimed is:

- 10 **1.** A power cable polymer connector, comprising a poly-
 meric insulating tube comprising a cable insertion hole to
 allow an insertion of a stripped end of a power cable,
 wherein the polymeric insulating tube further comprises
 an insulation comprising a polymer-based material and
 an embedded pipe comprising a metal and embedded
 on an inner peripheral surface of the insulation so as to
 15 face the end of the power cable.
- 2.** The power cable polymer connector according to claim
1, wherein the embedded pipe comprises an outer peripheral
 surface not more than 6.3 μm in an arithmetic mean rough-
 ness Ra.
