(57) **ABSTRACT**

A wearable device may include: a strap including a substantially polygonal opening and a buckle formed at one end thereof; a buckle part configured to fasten opposite ends of the strap to each other by binding the opposite ends of the strap; and a body configured to be coupled to the opening by being fitted into the opening or decoupled from the opening. The body may include a front surface and a rear surface, and a display having a substantially polygonal shape when viewed from the top on the front surface, and a biometric sensor disposed on the rear surface.

**CURVED BODY AND WEARABLE DEVICE  
THEREWITH**

CLAIM OF PRIORITY

The present application claims priority under 35 U.S.C. §119 to an application filed in the Korean Intellectual Property Office on Feb. 22, 2014 and assigned Serial No. 10-2014-0020974, the entire contents of which are incorporated herein by reference.

BACKGROUND

1. Technical Field

The present disclosure generally relates to an electronic device that is worn on a human body.

2. Description of the Related Art

Methods for a user to carry a portable electronic device include carrying the device in the user's pocket or bag, holding the device in the user's hand, or carrying the device by wearing it on a predetermined location of a human body. A wearable device can be worn on various parts of the human body and used.

Wearable devices may be worn on the human body in various ways as follows:

1. A wearable device may be worn on a human body such as a wrist like a watch or band;
2. A strap-type wearable device may be worn on a human body like a necklace; and
3. A glasses-type wearable device may be worn on user's face;
4. A clip-type wearable device may be worn by being clipped to a human body, clothing, or user's belongs; and
5. There are many other methods for attaching a wearable device to a human body, belongs, or an accessory directly or indirectly.

In addition, a wearable device may include a body and a wearing part (a strap or band), and may be worn on various parts of a human body according to a configuration of the wearing part. The wearable device may be one of the following structures:

1. a structure in which the body and the wearing part are integrally formed with each other and inseparable from each other;
2. a structure in which the body and the wearing part are separable from each other and thus are changeable.

Currently available wearable devices have several deficiencies. For example, the body of the wearable device is mostly designed regardless of design aspects and the exterior of the body and the inner wearing part are mostly formed according to the same flat/curved shape or a basic design shape.

Such a shape is not appropriate to the wearable device and acts as a factor delimiting functions and design of the wearable device.

In addition, where the wearable device has the body and the wearing part are integrally formed with each other, the body and the wearing part are not changeable and thus there is a limitation to providing various designs and customized functions. Furthermore, if the body and the wearing part are separable from each other and changeable, it would be possible to customize the wearable device according to a user's taste in view of an exterior design or function. However, there is a contradiction between the degree of fastening and convenience in removing the body, and deterioration of the wearing part caused by an individual using

pattern or frequent replacement may cause a serious problem in the fixing stability of the device.

SUMMARY

5

In an aspect of the present disclosure a wearable device is provided which has a body exterior configured to be easy to wear and to smoothly perform functions, and that facilitates housing electronic parts in the body of the device.

10 In another aspect of the present disclosure a wearable device that is easy for a user to wear on the user's wrist is provided.

Another aspect of the present disclosure may be to provide a wearable device that includes a removable body and includes a wearing part that may be changed according to a user's taste.

Another aspect of the present disclosure may be to provide a wearable device in which a place where a biometric sensor is mounted is configured to easily contact the skin of a human body, and where the biometric sensor can be used as a personal auxiliary medical device.

Another aspect of the present disclosure is to provide a wearable device, which provides coupling and decoupling directions of a body, and thus can prevent or inhibit the body from being decoupled when being worn on a wrist.

According to an aspect of the present disclosure, a wearable device may include: a strap having a first end and a second end. The strap may include a substantially polygonal opening and a buckle formed at one of the first and second ends of the strap. A buckle part may be configured to fasten the first and second ends of the strap to each other by binding the opposite ends (i.e., the first and second ends) of the strap. A body may be configured to be coupled to the opening by being fitted into the opening or decoupled from the opening. The body may include a front surface and a rear surface, and may also include a display having a substantially polygonal shape when viewed from the top, on the front surface. A biometric sensor may be disposed on the rear surface of the body.

According to another aspect of the present disclosure, a wearable device may include: a body housing; a curved display disposed on a front surface of the body housing; a curved battery layered under the curved display; and a curved body including one or a plurality of substrates arranged between the curved battery and the rear surface of the body housing.

According to an embodiment of the present disclosure, the wearable device may include a wearing part that is changeable or replaceable (e.g., decoupled from the body) such that a user may select a wearing part according to the user's taste. Thus, the user can select a wearing part reflecting consumer's personality.

Another aspect of the present disclosure may be to provide a wearable device provided with a wearing structure that is able to respond to various wrist curvatures. For example, the a wearing part may able to respond to various wrist curvatures, thereby improving wearability. The wearable device may include a body housing, a curved display disposed on a front surface of the body housing, a curved battery layered under the curved display, and a curved body comprising at least one substrate arranged between the curved battery and the rear surface of the body housing.

According to another embodiment of the present disclosure, the wearable device may include a wearable part and a body that may be coupled or decoupled from one another by moving the wearable part and the body relative to one another in either a coupling or decoupling direction. The

coupling and decoupling directions may be such that the body is inhibited from being inadvertently separated from the wrist and is stably worn on the user's wrist.

These and other aspects of the present disclosure will be more fully described with reference to the appended drawings.

#### BRIEF DESCRIPTION OF THE DRAWINGS

For a more complete understanding of the present disclosure and its advantages, reference is now made to the following description taken in conjunction with the accompanying drawings, in which like reference numerals represent like parts:

FIG. 1 is a block diagram schematically showing an inner configuration of a network environment including an electronic device;

FIG. 2 is a perspective view showing a wearable electronic device including a wearable part and a curved body according to an embodiment of the present disclosure;

FIG. 3 is a perspective view showing the wearable electronic device of FIG. 2 in which the body and the wearing part are separated from each other;

FIG. 4 is a perspective view showing a front surface of the curved body of FIG. 2;

FIG. 5 is a perspective view showing a rear surface of the body of FIG. 2;

FIG. 6 illustrates a side view of the body of FIG. 2;

FIG. 7 is a side cross-sectional view of the body of FIG. 2;

FIG. 8 is a side cross-sectional view of the body of FIG. 2 showing an inner bracket and a display, which are coupled to each other according to various embodiments of the present disclosure;

FIG. 9 illustrates a side view of the body of FIG. 2 with parts removed;

FIG. 10 is an exploded perspective view of a curved display according to an embodiment of the present disclosure;

FIG. 11 illustrates a perspective view of a curved battery according to an embodiment of the present disclosure;

FIG. 12 is a plan view showing a front surface of a body housing according to an embodiment of the present disclosure;

FIG. 13 is a partial cutaway perspective view showing a curved body prior to being mounted on a wearing part according to an embodiment of the present disclosure;

FIG. 14 is a partial cutaway perspective view showing a waterproof structure applied to a plurality of parts of a wearable device according to an embodiment of the present disclosure;

FIG. 15 is a partial cutaway perspective view showing a waterproof structure applied to a side key of a wearable device according to an embodiment of the present disclosure;

FIG. 16 is a partial cutaway perspective view showing a waterproof structure applied to a charging terminal of a wearable device according to various embodiments of the present disclosure;

FIG. 17A and FIG. 17B illustrate a section view showing boundary areas between a body and a wearing part according to various embodiments of the present disclosure;

FIG. 18 illustrates a view showing an example of an assembly order of a wearable device according to various embodiments of the present disclosure;

FIG. 19 is a side view showing a body and a wearing part of a wearable device, which are separated from each other, according to an embodiment of the present disclosure;

FIG. 20 illustrates a side view showing a curved body that is coupled to a wearing part according to an embodiment of the present disclosure;

FIG. 21 is a perspective view according to an embodiment of a wearing part provided on a wearable device according to an embodiment of the present disclosure;

FIG. 22 is a perspective view showing an embodiment of a wearing part provided on a wearable device according to an embodiment of the present disclosure;

FIG. 23A is a side view showing an embodiment of a wearing part provided on a wearable device according to an embodiment of the present disclosure;

FIG. 23B is a perspective view of the wearing part of FIG. 23A;

FIG. 24A is a perspective view showing an embodiment of a wearing part provided on a wearable device according to an embodiment of the present disclosure;

FIG. 24B is a side view of the wearing part of FIG. 24A;

FIG. 25 is a perspective view showing a wearable device that is coupled to a cradle according to various an embodiment of the present disclosure;

FIG. 26 is a perspective view showing a part of a cradle according to an embodiment of the present disclosure; and

FIG. 27 is a perspective view showing a part of a body housing of a wearable device according to an embodiment of the present disclosure.

#### DETAILED DESCRIPTION

Hereinafter, the present disclosure will be explained with reference to the accompanying drawings.

The term "substantially" used in the embodiments of present disclosure is used to imply that a cited characteristic, parameter, or value is not necessarily achieved exactly and that an allowable error, a measurement error, a limitation of measurement accuracy, a deviation or change including other elements known to a person skilled in the art, and an effect that a characteristic is to provide are not excluded.

Although specific embodiments of the present disclosure are illustrated in the drawings and relevant detailed descriptions are provided, various changes can be made and various embodiments may be provided. Accordingly, various embodiments of the present disclosure are not limited to the specific embodiments and should be construed as including all changes, equivalents or substitutes included in the ideas and technological scopes of embodiments of the present disclosure. In the explanation of the drawings, similar reference numerals are used for similar elements.

The terms "include" or "may include" used in the embodiments of the present disclosure indicate the presence of disclosed corresponding functions, operations, elements, and the like, and do not limit additional one or more functions, operations, elements, and the like. In addition, it should be understood that the terms "include" or "have" used in the embodiments of the present disclosure are to indicate the presence of features, numbers, steps, operations, elements, parts, or a combination thereof described in the specifications, and do not preclude the presence or addition of one or more other features, numbers, steps, operations, elements, parts, or a combination thereof.

The term "or" used in the embodiments of the present disclosure includes any and all combinations of words enumerated with it. For example, "A or B" means including A, including B, or including both A and B.

Although the terms such as “first” and “second” used in the various embodiments of the present disclosure may modify various elements of the various embodiments, these terms do not limit the corresponding elements. For example, these terms do not limit an order and/or importance of the corresponding elements. These terms may be used for the purpose of distinguishing one element from another element. For example, a first user device and a second user device all indicate user devices and may indicate different user devices. For example, a first element may be named a second element without departing from the scope of right of the various embodiments of the present invention, and similarly, a second element may be named a first element.

It will be understood that when an element is mentioned as being “connected” or “coupled” to another element, the element may be directly connected or coupled to another element, and there may be an intervening element between the element and another element. To the contrary, it will be understood that when an element is mentioned as being “directly connected” or “directly coupled” to another element, there is no intervening element between the element and another element.

The terms used in the various embodiments of the present disclosure are for the purpose of describing specific embodiments only and are not intended to limit the present disclosure. As used herein, the singular forms are intended to include the plural forms as well, unless the context clearly indicates otherwise.

All of the terms used herein including technical or scientific terms have the same meanings as those generally understood by an ordinary skilled person in the related art unless they are defined otherwise. The terms defined in a generally used dictionary should be interpreted as having the same meanings as the contextual meanings of the relevant technology and should not be interpreted as having ideal or exaggerated meanings unless they are clearly defined in the various embodiments.

An electronic device according to various embodiments of the present disclosure may be a device that is equipped with a communication function. For example, the electronic device may include at least one of a smartphone, a tablet personal computer (PC), a mobile phone, a video phone, an electronic book reader, a desktop PC, a laptop PC, a netbook computer, a Personal Digital Assistant (PDA), a Portable Multimedia Player (PMP), an MP3 player, a mobile medical machine, a camera, or a wearable device (e.g., a head-mounted-device (HMD) such as electronic glasses, electronic clothing, an electronic bracelet, an electronic necklace, an electronic appcessory (e.g., an accessory (e.g., a heart monitor) configured to work with an application of the electronic device), electronic tattoos, or a smartwatch).

According to an embodiment, the electronic device may be a smart home appliance that is equipped with a communication function. For example, the smart home appliance may include at least one of a television, a Digital Video Disk (DVD) player, a stereo, a refrigerator, an air conditioner, a cleaner, an oven, a microwave oven, a washing machine, an air cleaner, a set-top box, a TV box (for example, Samsung HomeSync™, Apple TV™, or Goggle TV™), a game console, an electronic dictionary, an electronic key, a camcorder, or an electronic album.

According to an embodiment, the electronic device may include at least one of various medical machines (for example, Magnetic Resonance Angiography (MRA), Magnetic Resonance Imaging (MRI), Computerized Tomography (CT), a tomograph, an ultrasound machine, and the like), a navigation device, a Global Positioning System

(GPS) receiver, an Event Data Recorder (EDR), a Flight Data Recorder (FDR), an automotive infotainment device, electronic equipment for ship (for example, a navigation equipment for ship, a gyro compass, and the like), avionics, a security device, or an industrial or home robot.

According to an embodiment, the electronic device may include at least one of a part of furniture or a building/a structure including a communication function, an electronic board, an electronic signature receiving device, a projector, and various measurement devices (for example, water, power, gas, radio waves, and the like). The electronic device according to various embodiment of the present disclosure may be one or a combination of one or more of the above-mentioned devices. In addition, it is obvious to an ordinary skilled person in the related art that the electronic device according to various embodiments of the present disclosure is not limited to the above-mentioned devices.

Hereinafter, an electronic device according to various embodiments will be explained with reference to the accompanying drawings. The term “user” used in the various embodiments may refer to a person who uses the electronic device or a device that uses the electronic device (for example, an artificial intelligence electronic device).

FIG. 1 illustrates a network environment **100A** including an electronic device **101A** according to various embodiments of the present disclosure. Referring to FIG. 1, the electronic device **101A** may include a bus **110A**, a processor **120A**, a memory **130A**, an input and output interface **140A**, a display **150A**, a communication interface **160A**, and a sensor module **170A**.

The bus **110A** may be a circuit, which connects the above-described elements with one another and transmits communication signals (for example, a control message) between the above-described elements.

The processor **120A** may receive instructions from the other elements (for example, the memory **130A**, the input and output interface **140A**, the display **150A**, the communication interface **160A**, or the sensor module **170A**) via the bus **110A**, decipher the instructions, and perform calculation or data processing according to the deciphered instructions.

The memory **130A** may store instructions or data which is received from or generated by the processor **120A** or the other elements (for example, the input and output interface **140A**, the display **150A**, the communication interface **160A**, the sensor module **170A**, and the like). For example, the memory **130A** may include programming modules such as a kernel **131A**, middleware **132A**, an Application Programming Interface (API) **133A**, an application **134A**, and the like. Each of the above-described programming modules may be configured by software, firmware, hardware, or a combination of two or more of them.

The kernel **131A** may control or manage system resources (for example, the bus **110A**, the processor **120A**, the memory **130A**, and the like) which are used for performing operations or functions implemented in the other programming modules, for example, the middleware **132A**, the API **133A**, or the application **134A**. In addition, the kernel **131A** may provide an interface for allowing the middleware **132A**, the API **133A**, or the application **134A** to access an individual element of the electronic device **101A** and control or manage the element.

The middleware **132A** may serve as an intermediary to allow the API **133A** or the application **134A** to communicate with the kernel **131A** and exchange data with the kernel **131A**. In addition, the middleware **132A** may perform controlling (for example, scheduling or load balancing) with respect to work requests received from the application **134A**,

for example, by giving priority to use the system resources of the electronic device **101** (for example, the bus **110A**, the processor **120A**, the memory **130A**, and the like) to at least one of the applications **134A**.

The API **133A** may be an interface for allowing the application **134A** to control a function provided by the kernel **131A** or the middleware **134A**, and, for example, may include at least one interface or function (for example, instructions) for controlling a file, controlling a window, processing an image, and/or controlling a text.

According to various embodiments, the application **134A** may include a Short Message Service (SMS)/Multimedia Messaging Service (MMS) application, an email application, a calendar application, a notification application, a health care application (for example, an application for measuring exercise or a blood sugar), an environment information application (for example, an application for providing information on atmospheric pressure, humidity, or temperature), and the like. Additionally or alternatively, the application **134A** may be an application related to information exchange between the electronic device **101A** and an external electronic device (for example, an electronic device **102A** or an electronic device **104A**). For example, the application related to the information exchange may include a notification relay application for relaying specific information to the external electronic device or a device management application for managing the external electronic device.

For example, the notification relay application may include a function of relaying notification information generated by other applications of the electronic device **101A** (for example, the SMS/MMS application, the email application, the health care application, the environment information application, and the like) to the external electronic device (for example, the electronic device **102A** or the electronic device **104A**). Additionally or alternatively, the notification relay application may receive notification information from the external electronic device (for example, the electronic device **102A** or the electronic device **104A**) and may provide the same to the user. For example, the device management application may manage (for example, install, delete or update) a function regarding at least part of the external electronic device (e.g., the electronic device **102A** or the electronic device **104A**) communicating with the electronic device **101A** (for example, turning on/off the external electronic device (or some parts) or adjusting brightness of a display), an application operating in the external electronic device or a service provided by the external electronic device (e.g.: a calling service or a message service).

According to various embodiments, the application **134A** may include an application specified according to an attribute (for example, a kind of an electronic device) of the external electronic device (for example, the electronic device **102A** or the electronic device **104A**). For example, when the external electronic device is an MP3 player, the application **134A** may include an application related to music replay. Similarly, when the external electronic device is a mobile medical device, the application **134A** may include an application related to health care. According to an embodiment, the application **134A** may include at least one of an application specified by the electronic device **101A** or an application received from the external electronic device (for example, a server **106A**, the electronic device **102A**, or the electronic device **104A**).

The input and output interface **140A** may transmit instructions or data input by a user through a sensor (for example,

an acceleration sensor or a gyro sensor) or an input device (for example, a keyboard or a touch screen) to the processor **120A**, the memory **130A**, or the communication interface **160A** through the bus **110A**, for example. For example, the input and output interface **140A** may provide data on a user's touch input through a touch screen to the processor **120A**. In addition, the input and output interface **140A** may output instructions or data received from the processor **120A**, the memory **130A**, the communication interface **160A**, or the sensor module **170A** through the bus **110A** through an output device (for example, a speaker or a display). For example, the input and output interface **140A** may output voice data processed through the processor **120A** to the user through a speaker.

The display **150** may display a variety of information (for example, multimedia data, text data, and the like) for the user.

The communication interface **160A** may connect communication between the electronic device **101A** and the external device (for example, the electronic device **102A**, the electronic device **104A**, or the server **106A**). For example, the communication interface **160A** may support network communication **162A** (for example, the Internet, a Local Area Network (LAN), A Wire Area Network (WAN), a telecommunication network, a cellular network, a satellite network, a Plain Old Telephone Service (POTS), and the like), and short-distance communication **164A** (for example, Wireless Fidelity (WiFi), Bluetooth (BT), Near Field Communication (NFC), or wired communication (for example, a Universal Serial Bus (USB), a High Definition Multimedia Interface (HDMI), a Recommended Standard 232 (RS-232), or POTS)). According to an embodiment, a protocol for communicating between the electronic device **101A** and the external device (for example, a short-distance communication protocol, a network communication protocol, or a wired communication protocol) may be supported in at least one of the API **133A** or the middleware **132A**. The electronic device **102A**, **104A** may be the same device as the electronic device **101A** (for example, the same type of device) or a different device (for example, a different type of device).

The sensor module **170A** may measure a physical quantity or detect an operation state of the electronic device, and may convert measured or detected information into electric signals. The sensor module **170A** may include at least one of a gesture sensor, a gyro sensor, a barometric pressure sensor, a magnetic sensor, an acceleration sensor, a grip sensor, a proximity sensor, a color sensor (for example, Red, Green, Blue (RGB) sensor), a biosensor, a temperature/humidity sensor, an illumination sensor, and a Ultraviolet (UV) sensor.

Additionally or alternatively, the sensor module **170A** may include an E-nose sensor, an electromyography (EMG) sensor, an electroencephalogram (EEG) sensor (not shown), an electrocardiogram (ECG) sensor (not shown), an infrared ray (IR) sensor, an iris sensor (not shown), a fingerprint sensor, and the like.

FIG. 2 is a perspective view showing a wearable device according to various embodiments of the present disclosure. FIG. 3 is a perspective view showing a wearable device in which a curved body **10** and a wearing part **20** are separated from each other according to various embodiments of the present disclosure.

Referring to FIGS. 2 and 3, a 3-dimensional X/Y/Z orthogonal coordinate system is illustrated. "Z-axis" is a vertical direction and means an up and down direction (thickness direction) of the body **10**, "X-axis" is a first horizontal direction and means a widthwise direction of the

body 10, and “Y-axis” is a second horizontal direction perpendicular to the first horizontal direction and means a lengthwise direction of the body 10.

The wearable device according to various embodiments of the present disclosure is a user device, which is worn on a human body, and may be an electronic device that is relatively easy to wear on a wrist like a watch or bracelet, a communication device, or an auxiliary medical device. However, the wearable device according to various embodiments of the present disclosure is not limited to the device that is worn on a wrist. For example, the wearable device according to various embodiments of the present disclosure can be equally applied to any part of the human body where a curvature exists. For example, examples of a part of the human body where a curvature exists may be a wrist, an arm, an ankle, or the like. In addition, the wearable device according to various embodiments of the present disclosure can be stably worn on various parts of the body when the wearing part 20 is configured in various ways.

The wearable device according to various embodiments of the present invention may include the body 10 (function device part) and the wearing part 20 (including a band or strap). The body 10 may be configured to be forcibly coupled to or decoupled from the wearing part 20. The body 10 may include a display 11 for externally displaying a variety of information, and a press key (e.g., a side key) (k), a sensor (s), a touch input part, and the like for inputting a variety of information. The body 10 may be formed in a bar shape and may also have a curvature. Specifically, the body 10 may have a shape extending in the lengthwise direction (Y-axis direction) and may have a curvature.

The wearing part 20 may be made of an elastic material and allows the body 10 to be worn on a human body stably and brings the body 10 into close contact with the skin of the human body. In addition, since the wearing part 20 is changeable, the wearing part 20 may function as an accessory reflecting user’s personality or taste. However, a part (seating part) of the wearing part 20, which is coupled to the body 10, may be configured to be elastically deformable and a wearing surface part, which is in close contact with the human body, may not be made of an elastic material. The wearing part 20 may be provided with an opening 21 which is opened in the up and down directions, and may include a seating part 22 which is elastically deformable along a circumference of the opening 21. The wearing part 20 includes an elastic member (seating part) at least around the opening 21, and, when the body 10 is coupled to the wearing part 20, at least part of the seating part including the elastic member may be fitted into or mated with a seating recess which extends along a side surface of the body 10.

The opening 21 is an open space into which the body 10 is fitted and has a shape enclosed by the seating part 22. The opening 21 according to the present embodiment may be formed in a substantially rectangular shape having a thickness. The opening 21 may have a substantially rectangular shape when viewed from the top, having the side in a first direction longer than the side in the direction perpendicular to the first direction. In addition, the opening 21 includes at least one linear portion enclosing the opening 21. Two linear portions may be provided and configured in parallel with each other, facing each other. The wearing part 20 may include a buckle part for fastening both ends of the wearing part 20 by binding the ends. The wearing part 20 may be configured to include a band extending in the first direction (Y-axis direction). The band includes an opening formed on a part thereof, and includes a buckle part formed at one end thereof and a fastening part formed at the other end to be

removably fastened to the buckle part. In addition, the curved display 11 may be configured to have a substantially rectangular shape smaller than the opening 21, when viewed from the top.

In addition, the wearable device according to embodiments of the present disclosure may include a removable structure which enables the body 10 to be mechanically coupled/decoupled, and the removable structure includes a seating recess 13 provided on the body 10, and the opening 21 and the seating part 22 provided on the wearing part 20.

The wearable device may include the seating recess 13 formed along the circumference of the side surface of the surfaces of a body housing, and the seating part 22 formed on the wearing part 20 to be fitted into the seating recess 13. After the body 10 is fitted into the seating part 22, the body 10 can be more securely fixed to the wearing part 20 by other means (not shown).

The body 10 may be curved and hereinafter is referred to as a curved body. However, it is to be understood that the body 10 is not limited to a curved configuration and may instead, for example, be generally planar, flat, and/or rectangular. The curved body 10 will be explained in detail below. The seating part 22 is made of an elastic material and may be elastically deformable, the curved body 10 is removable from the seating part 22. In addition, due to the shape of the curved body 10 and the removable structure, the body 10 may be forcibly coupled to or decoupled from the wearing part with directions.

The wearing part 20 may be changeable, and may be changed according to a user’s taste when the wearing part 20. The wearing part 20 may be implemented in various designs or colors such that the wearing part 20 may be regarded as an accessory reflecting the user’s own personality and tastes.

FIG. 4 is a perspective view showing a front surface 120 of the curved body 10 according to various embodiments of the present disclosure. FIG. 5 is a perspective view showing a rear surface 121 of the curved body 10 according to various embodiments of the present disclosure. FIG. 6 is a side view showing the curved body 10, which is coupled to the seating part of the wearing part 20, according to various embodiments of the present disclosure. The exterior configuration of the curved body 10 will be explained in detail with reference to FIGS. 4 to 6.

The curved body 10 according to various embodiments of the present disclosure is formed in a bar shape such as a rectangular shape, extends in a curved direction, and has an elongated shape, while having a curvature. The curved body 10 may include a body housing 12 and a display 11, which may be mounted in the body housing 12. The body housing 12 includes a front surface 120, a rear surface 121, and a side surface 122, and the front surface 120 and the rear surface 121 each has a curvature. The front surface 120 is a surface where the display 11 is mounted, and the rear surface 121 is a wearing surface which is in contact with a human body. The front surface 120 has a first curvature and the rear surface 121 has a second curvature. The first and second curvatures may be determined to facilitate improved consumer wearability by having a shape or configuration to ergonomically correspond to various consumers’ wrists. In the present embodiment, the first curvature is smaller than the second curvature. In other words, the front surface 120 of the curved body 10 according to the present embodiment has the display 11 mounted therein and thus should make it easy for a user to view a displayed screen, and the rear surface 121 should make the user feel good when the user

## 11

wears the device on user's wrist, and has a sensor mounted thereon and thus should provide a shape closely contacting user's wrist.

The curved body 10 may be configured to gradually become thinner from the center toward the opposite sides thereof. The curved body 10 may be relatively thick on the center and may gradually become thinner toward the sides. In addition, although the rear surface 121 has the second curvature in the above-described embodiment, the rear surface 121 may be a substantially flat surface without a curvature.

The exterior structure of the curved body 10 can ergonomically improve a sensation that a user may feel when wearing the device and can improve compatibility in response to various consumers' wrists. The curved body 10 may be provided with the curved display 11 on the front surface 120 and may include a skin contact surface provided with a sensor 13 (an interface of the sensor is seen in FIG. 4) on the rear surface 121, so that the degree of freedom of the exterior design can be maximized and optimal sensor performance can be provided to all of the users. In particular, the rear surface 121 of the curved body 10, which is the skin contact surface, may be configured as a nearly flat surface in comparison to the free shape of the exterior design of the curved body 10, and may have the sensor (s) arranged thereon to respond to all of the various body curvatures appropriately.

In addition, the curved body housing 12 in the present embodiment may have a sensor interface (SW) formed on the rear surface thereof which is in close contact with user's skin, and has the display, a touch input part, a button key, a charging terminal, and an information interface formed on a surface other than the skin contact surface (bottom surface of the body housing).

The display 11 is formed in a shape reflecting a curved shape of the human body and may be formed in a flat shape (Liquid Crystal Display (LCD), Organic Light Emitting Diode (OLED)) or a curved shape (flexible OLED). Although the display 11 is provided in the present embodiment is described as being curved, the display 11 may instead be configured as a flat display.

A seating recess 13 may be formed on the side surface of the curved body housing 12. The seating recess 13 extends along the side surface 122 of the curved body housing 12. An exterior side surface of the side surfaces of the curved body housing 12 that is seen by the user has a curvature. The seating recess 13 has the same curvature as the first curvature of the front surface 120 of the curved body housing 12. However, the curvature of the seating recess 13 may be the same as the first curvature, but may be larger or smaller than the first curvature since men and woman have various wrist curvatures. In FIG. 6, the curvature of the seating recess 13 is the same as the first curvature. As will be described, the seating recess 13 includes a top surface curvature and a bottom surface curvature in some section. The bottom surface curvature may vary to respond to various wrist curvatures. The top surface curvature and the bottom surface curvature of the seating recess 13 may vary in a boundary area with the body according to a wrist curvature of a user who wears the wearable device.

In the above-described embodiment, the seating recess 13 has a curvature, and a top surface 33a and a bottom surface 33b of the seating recess 13 have the same curvature. The seating recess 13 formed on the outside surface of the body housing 12 may extend to have the curvature with the same width and the same thickness and thus the top surface 33a

## 12

and the bottom surface 33b of the seating recess 13 have the same curvature as the first curvature.

FIG. 7 is a section view showing arrangement of electronic parts provided in the curved body 10 according to various embodiments of the present disclosure. FIG. 8 is a side view showing the curved body 10 according to various embodiments of the present disclosure. FIG. 9 is a side view showing arrangement of substrates and electronic parts provided in the curved body 10 according to various embodiments of the present disclosure.

Arrangement of electronic parts mounted in the curved body 10 will be explained with reference to FIGS. 7 to 9. In the present embodiment, a curved battery 14 is mounted under the display 11 in a layered structure, such that the curved body 10 gradually becomes thinner from the center toward the opposite sides. That is, the curved body 10 has the curved display 11, the curved battery 14, and substrates P1-P3 layered therein one on another.

In the present embodiment, the curved body 10 may be configured such that an exterior surface which is easily seen with user's eyes (for example, a display screen) and a contact surface which is worn on a human body and is in close contact with a skin (a rear surface of the body housing) have different curvatures, and has an optimum layered structure of electronic parts mounted therein. The curved body 10 according to the present embodiment is provided with the display 11 having the highest degree of freedom of manufacturing a curved surface on the exterior surface having the largest curvature, and has the battery 14 installed inside the display 11. In this case, the battery 14 has a curved shape and has the same curvature as the first curvature. The battery 14 may be mounted with reference to the center of the curved display 11, and facilitates providing or guaranteeing mounting spaces that are formed at both ends of the battery. The mounting spaces may be used as spaces for compensating for reduction in the curvature of the skin contact surface (rear surface). The above-described mounting structure results in reduction in the thickness at the both ends in comparison to the center of the curved body 10, thereby achieving a good design and minimizing a step height which may be generated with respect to the wearing part 20.

Hereinafter, the arrangement of various electronic parts and substrates mounted in the curved body 10 will be explained.

The curved battery 14, a plurality of electronic parts s, m, and c and a plurality of substrates P1, P2, and P3 are arranged in the curved body 10. The curved display 11, the curved battery 14, and the plurality of substrates P1, P2, and P3 are arranged in the curved body 10 in a vertically layered structure. In particular, the battery 14 according to the present embodiment is disposed on an intermediate layer between the curved display 11 and the substrate P1. This structure is to serve as a safety device for preventing a low temperature burn caused by heat emitted from the battery and minimizing any damage to the user caused by explosion of the battery, and may be a vertically layered structure.

The curved body 10 includes the curved body housing 12 and an inner bracket 15. The curved body 10 forms a single body by coupling the inner bracket 15 to the curved body housing 12. The body housing 12 and the inner bracket 15 may be independently manufactured and coupled to each other. However, the inner bracket 15 may be included in the body housing 12. The curved display 11 may be attached to the front surface of the body housing 12 by an adhesive tape (double-sided waterproof tape), and the inner bracket 15 may be received in and fixed to the body housing 12. The

inner bracket **15** may receive the curved battery which is layered under the curved display **11** and one or the plurality of substrates **P1**, **P2**, and **P4** arranged between the front surface **120** and the rear surface **121** of the body housing **12**.

In addition, according to the present embodiment, the plurality of substrates **P1**, **P2**, and **P4** may be arranged in the inner space of the body housing **12**, specifically, in the inner bracket **15**. In this case, a segmental (articular) structure substrate may be applied, thereby improving efficiency of mounting of the electronic parts. The above-mentioned segmental structure substrate appropriately provides rigid substrates **P1**, **P2**, and **P3** and flexible substrates **F1** and **F2** to sections where the substrates are needed, thereby smoothly implementing a curved design, and may have the electronic parts directly arranged in respective segmental sections separately according to a required condition, thereby improving performance of the electronic device. For example, a part vulnerable to a noise and a noise generating part may be arranged on separate substrates and a part vulnerable to a shock and a shock generating part may be arranged on separate substrates. Such arrangement of the electronic parts may naturally separate a noise generating section and a noise sensitive section from each other and may block a vibration shock transmitted through the rigid substrates **P1**, **P2**, and **P3** in the section of the flexible substrates **F1** and **F2**, thereby achieving a design for optimizing electrical performance of the electronic device and durability. In the future, a curved rigid or flexible substrate will be applicable instead of the above-described rigid substrate thanks to the technology development. In the above-described substrate segmental structure, a non-contact sensor such as a gyro sensor, an acceleration sensor, and/or other optical sensors may be further provided in addition to the basic parts related to communication or input and output.

The plurality of substrates may include the plurality of rigid substrates (for example, Printed Circuit Boards (PCBs)) and the plurality of flexible substrates (PCBs), and the rigid substrates **P1**, **P2**, and **P3** are substrates where various electronic parts are mounted and the electronic parts may be mounted on both the top surface and the bottom surface of each of the rigid substrates **P1**, **P2**, and **P3**. In FIG. **7**, three rigid substrates are mounted and are referred to as a first substrate **P1**, a second substrate **P2**, and a third substrate **P3**. The first substrate **P1** is disposed in the center, the second substrate **P2** is disposed on the right of the first substrate **P1**, and the third substrate **P3** is disposed on the left of the first substrate **P1**. A substrate connecting the first substrate **P1** and the second substrate **P2** is referred to as a first flexible substrate **F1**, and a substrate connecting the first substrate **P1** and the third substrate **P3** is referred to as a second flexible substrate **F2**. The first, second, and third substrates **P1**, **P2**, and **P3** and the first and second flexible substrates **F1** and **F2** are connected with one another, thereby configuring the segmental substrate.

In addition, when various electronic parts are arranged on the first, second, and third substrates **P1**, **P2**, and **P3**, parts vulnerable to a noise and noise generating parts may be arranged on separate substrates, and parts vulnerable to a shock and shock generating parts may be arranged on separate substrates.

For example, out of the electronic parts mounted on the substrates, a part vulnerable to a noise (PAM) and a noise generating part (AP, CP) may be separately arranged on the first and second rigid substrates **P1** and **P2**, respectively, and a part vulnerable to a shock (a BGA part such as AP and CP) and a shock generating part (for example, a vibrator or a

vibration motor) may be separately mounted on the second and third substrates **P2** and **P3**, respectively. Such inner arrangement of the electronic parts can naturally separate a noise generating section and a noise sensitive section from each other, and block a vibration shock transmitted through the rigid substrates in the flexible substrate section, thereby achieving a design for optimizing electrical performance of the electronic device and durability.

In addition, at least one of the rigid substrates disposed on the rear surface **121** of the body housing **12** may be horizontally placed or may be slantingly placed. The first substrate **P1** is disposed in the center and has a first sensor (s) (which is exposed from the rear surface of the body housing and is in close contact with a skin of a human body to acquire a variety of information on the human body) disposed thereon. Therefore, the first substrate **P1** should be placed horizontally along with the first sensor (s). The first sensor (s) may be exposed from the rear surface of the body housing and may be disposed on a location where the first sensor (s) is in the closest contact with the skin. That is, the first sensor (s) may be horizontally disposed substantially on the center of the rear surface **121** of the body housing. The first sensor (s) may be mounted on the rear surface of the first substrate **P1** and a sensor interface (sensor interface window) may further be provided. In addition, even when a PCB is mounted slantingly with respect to the exterior surface of the housing, a balance can be maintained by using an interposer between the PCB and the first sensor. The first sensor (s) may have the sensor interface window exposed from the rear surface **121** of the body and may be horizontally disposed. The sensor interface window may be provided on the sensor or may be attached to the exterior of the body housing. For example, the first sensor (s) may be a Heart Rate Monitor (HRM) or a vein sensor which can acquire information from user's skin or body.

Additionally, the first sensor (s) which is exposed from the rear surface **121** of the body housing may further include a protrusion **125** protruding toward the rear surface, while enclosing the circumference of the first sensor (s) with a predetermined thickness. The protrusion **125** may make the sensor interface, for example, the sensor interface window (SW), exposed and more brought into close contact with the skin. The sensor interface (SW) is located on a flat surface of the rear surface **121** and the flat surface is located on the center.

In the present embodiment, even when the segmental structure substrates are used, at least a horizontal and flat part seating plane part (an area where the first substrate is mounted in the body housing) should be provided to mount electronic parts, and the plane part requires a plane seating structure for performing a function such as a function of a sensor. In the present embodiment, when a space guaranteed at the both ends of the curved battery **14** is used as a mounting area, a loss in the mounting space caused by the substrate being mounted on the plane can be offset. In particular, when a relatively thick part such as a vibrator (m) or a connector is placed, an inevitable increase in the total thickness of the curved body can be prevented. Although not shown, various mechanism configurations such as a sub battery or a hook assembly can be mounted in the guaranteed space.

In the curved body **10** according to the present embodiment, the third substrate **P3** is disposed between the lower side of the display **11** and one side area of the battery **14** (Y-axis direction), and the motor (m) is disposed on the third substrate **P3** and the charging terminal (c) is disposed on the first substrate **P1**. The motor (m) is horizontally disposed in

## 15

parallel with the battery **14** and the charging terminal (c) is horizontally disposed in parallel with the battery **14**. The motor (m) is disposed on the top surface of the third substrate **P3** and the charging terminal (c) is disposed on the bottom surface of the first substrate **P1**. The charging terminal (c) is exposed from the rear surface **121** of the body housing. Since the motor (m) is a relatively thick part or a part of a great volume, it is advantageous to dispose the motor (m) on the second substrate **P2** or the third substrate **P3** in view of the efficiency of mounting.

As other input devices mounted in the substrates, an electric switch interface using a touch sensor, a pressure sensor, a temperature sensor, and the like, and a physical switch interface such as a tact dome key may be disposed on one surface of the body housing, on which the user can manipulate. Charging and interface terminals may further be disposed on a location of the front surface or the rear surface of the body housing that does not deface the exterior. In the present embodiment, the charging terminal (c) is disposed on the rear surface **121** of the body housing. According to the present embodiment, the surface that does not deface the exterior of the wearable device may be the rear surface of the body housing, that is, the surface which is in contact with the human body.

Hereinafter, the configuration of the display **11** disposed on the front surface of the curved body **10** will be explained.

FIG. **10** is an exploded perspective view showing the configuration of the curved display **11** provided in the curved body according to various embodiments. Referring to FIG. **10**, the display **11** applies a flexible LCD **110** having a curvature and a curved window **112** having the same curvature as that of the flexible LCD **110** to achieve a curved design having a curvature. The curved window **112** includes a rigid or flexible layer.

The display **11** has a shape reflecting a curved part of a human body and may include a curved LCD (flexible OLED). The design of the front surface of the body can be achieved by the curved surface of the LCD or the curved window **112** presenting a curved surface. The display **111** may further include a sensor for detecting a touch, pressure, or temperature in addition to the curved flexible LCD **110**, thereby providing a Perceptual User Interface (PUI) optimized to use of various user interface (UIs). In addition, the window **112** may provide a layer made of a ceramic material such as glass and a sheet material such as PET, PC, and the like to protect the surface.

FIG. **11** is a perspective view showing the curved battery **14** provided in the curved body according to various embodiments of the present disclosure. Referring to FIG. **11**, the battery **14** according to an embodiment of the present disclosure applies a curved battery pack, thereby improving efficiency of mounting of the electronic parts in the body. The curved battery **14** may be mounted in a bent state. This is a factor that is optimized to realize the exterior design of the curved body and mount an HW part of the wearable electronic device worn on the human body.

The battery **14** may be manufactured in a bent shape and configured to have a predetermined curvature. The front surface and the rear surface of the battery **14** each have a curvature. The curvature of the battery **14** may be the same as the curvature of the display and thus the battery **14** may be disposed to face the rear surface of the display. A mounting space may be formed on the center of the rear surface of the battery **14** and can be utilized effectively by mounting a hardware electronic part therein. The battery **14** may not have the same curvature as that of the display. In addition, although the battery **14** may be disposed between

## 16

the display and the substrate, the battery **14** may be configured in a flat shape and may be disposed on the bottom surface of the substrate.

Referring back to FIG. **7**, a separate layer part **142** may be added between the curved battery **14** and the first substrate **P1** to prevent breakage of parts of the first substrate **P1** and the battery caused by volume expansion of the curved battery **14**. The layer part **142** stops volume expansion of the battery **14**. The layer part **142** may act as a physical support structure or a buffering section for the curved battery **14** and the first substrate **P1**, and may be provided in the form of a barrier for preventing a battery liquid from leaking to the lower side. The layer part **142** may be provided as a conductive or metal piece or an injection molding piece.

FIG. **12** is a plan view showing the front surface **120** of the body housing according to an embodiment of the present disclosure. In the present embodiment, an assembly structure of the body housing **12** without a screw boss is provided. The inner bracket in which electronic parts are modularized and the body housing **12** may be fixed by a hook and the display window and the front surface **120** of the body housing may be assembled with each other by using a waterproof tape. Therefore, the inner mounting space can be maximized and the waterproof function can be maximized by excluding a screw boss. Reference numeral **120a** indicates a surface to which the waterproof tape is attached.

FIG. **13** is a partial cutaway perspective view showing the curved body prior to being mounted on the wearing part according to various embodiments of the present disclosure. Referring to FIG. **13**, a body removable structure provided in the wearable device according to an embodiment of the present disclosure and a direction of removal will be explained. In the present embodiment, an undue bending operation may occur between the body **10** and the seating part **22** due to a shape characteristic of the bar type body **10** having a curvature and various characteristics of body shape of the user. In this case, a structure may be configured to provide a removal force according to a direction of the present embodiment needs to fix the longitudinal end of the body **10** more tightly. The size of the seating part is designed to be smaller than the longitudinal size of the body so that the side surface of the body can be hold relatively stronger by elasticity of the wearing part. In addition, a separate bending prevention protrusion structure may be added to a certain section of the seating part facing the body with respect to the section where an undue bending operation occurs when the wearable device is worn on the human body.

Referring to FIG. **13**, the body **10**, that is, the body housing **12**, may be removable from the wearing part **20**. The direction of removal may include a coupling direction (that is the relative direction that the body housing **12** and the wearing part **20** move to effect coupling) in which the body **10** moves from bottom to top and is coupled to the seating part **22**, and a decoupling direction (that is the relative direction that the body housing **12** and the wearing part **20** move to effect decoupling) in which the body is pushed down and is decoupled from the wearing part **20**. The coupling direction refers to a direction in which the body coupled to the wearing part **20** is prevented or inhibited from being separated from the human body.

The curved body housing **12** may have a widthwise direction in which the width is gradually reduced from the rear surface or the center to the front surface, such that removal of the body housing **12** from the wearing part **20** may be accomplished by moving the body housing **12** and

the wearing part **20** apart from each other in a first direction but not in a second direction that is opposite that of the first direction, thereby providing a first removal direction. The width **W2** of the body housing **12** on the front surface in the widthwise direction (X-axis direction) is smaller than the width **W1** on the center (including the rear surface) in the widthwise direction. The body housing **12** having the above-described shape should be moved from bottom to top with reference to the seating part to be coupled to the seating part. The side surface of the body housing includes a first part enclosing between the recess **13** and the front surface **120** and a second part enclosing a part between the recess **13** and the rear surface **121**, and the width **W2** of the first part is set to be smaller than the width **W1** of the second part when viewed in a cross section of the body housing **12** cut perpendicularly to the first direction (Y-axis direction). The above-described structure provides the first removal direction.

In addition, the removal structure for coupling or decoupling the curved body housing **10** to or from the seating part **22** may be formed along the circumference of the opening provides a second direction of removal. The removal structure includes the seating recess **13** and the seating part **22**. The seating recess **13** may extend along the circumference of the side surface **122** of the curved body housing and continuously extends with the same curvature as the first curvature. The seating part **22** may be tightly coupled to the seating recess **13** to fix the curved body housing **10** to the opening **21**. The seating part **22** may be made of an elastic material and is elastically deformable according to whether the seating part **22** is coupled to the seating recess **13** or not, and the opening of the seating part is configured to be slightly smaller than the curved body housing so that the seating part is tightly coupled to the seating recess **13**. In particular, the seating part **22** may be coupled to the seating recess formed along the outer circumference of the side surface of the side surfaces **122** of the curved body housing to have the same curvature as the first curvature.

The seating recess **13** may be provided with a first close contact surface including a first top surface **130**, a first intermediate surface **131**, and a first bottom surface **132**. The seating recess **13** may be configured to have the horizontal width of the exterior corresponding to the first bottom surface **132** wider than the horizontal width of the exterior corresponding to the first top surface **130**. The first top surface **130** may be configured to be horizontally flat or substantially horizontally flat, and the first bottom surface **132** may be configured to be horizontally flat or substantially horizontally flat.

In addition, the seating part **22** includes a second close contact surface including a second top surface **220**, a second intermediate surface **221**, and a second bottom surface **222** and which is in close contact with the first close contact surface. The second top surface **220** may be configured to be horizontally flat or substantially horizontally flat and the second bottom surface **222** may be configured to be horizontally flat or substantially horizontally flat. The seating part **22** is configured to have the horizontal width of the exterior corresponding to the second bottom surface **222** wider than the horizontal width of the exterior corresponding to the first top surface **220** such that removal may be accomplished by moving the body **10** relative to the seating part **22** in one direction but is inhibited in the opposite direction, thereby providing the second removal direction.

The second close contact surface of the seating part **22** is formed in a shape corresponding to the first close contact surface of the seating recess **13**, so that the body can be

safely coupled to the wearing part and safely decoupled from the wearing part when necessary. Such a removal structure can prevent unexpected removal caused by a wearing pressure when the user does physical activity (can prevent the body from being decoupled from the wearing part).

Hereinafter, a waterproof structure of a wearable device according to an embodiment of the present disclosure will be explained with reference to FIGS. **14** to **16**. FIG. **14** is a partial cutaway perspective view showing a waterproof structure applied to a plurality of parts of the wearable device according to various embodiments of the present disclosure. FIG. **15** is a partial cutaway perspective view showing a waterproof structure applied to a side key of the wearable device according to various embodiments of the present disclosure. FIG. **16** is a partial cutaway perspective view showing a waterproof structure applied to a charging terminal of the wearable device according to various embodiments of the present disclosure. As shown in FIGS. **14** to **16**, the wearable device according to the present disclosure applies a uni body structure by coupling the body housing and the battery bracket, thereby minimizing the number of waterproof points. The wearable device according to the present disclosure includes a plurality of waterproof structures. The waterproof structure of the wearable device according to the present disclosure is applied to a place where the curved window **112** is disposed, a place where the side key (k) is disposed, a place where the sensor (s) is disposed, and a place where the charging terminal (c) is disposed.

First, the waterproof structure for the curved window **112** mounted on the front surface **120** of the body housing applies a waterproof tape (T1). The curved window **112** is attached to an adhesive surface of the circumference of the front surface **120** to which the waterproof tape T is attached by using the waterproof tape T1. The waterproof tape T1 is a double-sided tape and has an upper surface attached to the curved window **112** and a lower surface attached to the adhesive surface **120a** of the front surface (shown in FIG. **12**). Water is prevented from entering the body housing **12** by the waterproof tape T1.

Secondly, the waterproof structure for the side key (k) disposed on the side surface **122** of the body housing applies a waterproof tape T2. The waterproof tape T2 may be a double-sided tape and may be provided to enclose the side key (k). One surface of the waterproof tape T2 may be attached to the inner surface of the body housing where the side key is disposed, and the other surface is attached to a silicon rubber, so that water is prevented or inhibited from entering by the waterproof tape T2. In addition, the side key (k) includes a silicon rubber for providing a restoring force when it is pressed, and a waterproof protrusion P is tightly arranged along the circumference of the silicon rubber (see FIG. **15**) so that water is prevented from entering between the silicon rubber and the inner surface of the body housing. The silicon rubber prevents water from entering through the lower side by using the waterproof protrusion P and prevents water from entering the upper side by using the waterproof tape T2 placed on the lower side.

Thirdly, a waterproof structure using a waterproof tape T3 is applied to the sensor (s) disposed on the rear surface **121** of the body housing. The sensor (s) is provided with a sensor interface (sensor window) and the waterproof tape T3 is a double-sided tape and has one surface attached to the inner surface of the body housing and the other surface attached to the bottom surface of the sensor interface (sw). The

19

waterproof tape T3 is attached along the lower circumference of the sensor interface (sw).

Fourthly, a waterproof structure is applied to the charging terminal (c) disposed on the rear surface 121 of the body housing. The waterproof structure for the charging terminal (c) may be achieved by fitting a high elastic waterproof part R made of rubber or silicon material into the charging terminal (c). The waterproof part R is disposed between the side surface of the charging terminal and the inner wall of the body housing to prevent water from entering the charging terminal. In addition, a waterproof tape P4 is attached between the body of the charging terminal and the inner surface of the body housing to prevent water from entering the body of the charging terminal (c). In addition to the waterproof tape, various kinds of adhesive such as a bond, silicon, and the like may be used as a waterproof member.

FIGS. 17A and B is a section view showing a boundary area A between the body and the wearing part according to various embodiments of the present disclosure. Referring to FIGS. 17A and B, the configuration of the wearing part 20 according to various embodiments of the present disclosure will be explained. The wearing part includes a seating part and a band. When a user wears the wearable device on user's wrist, the wearing part 20 is subject to a pulling force in the boundary area A between the body 10 and the wearing part 20. In this state, there may be a gap between the body 10 and the wearing part 20 (the pulling force is concentrated) and the gap may deface the exterior. To prevent this problem, a coring section in the form of a cavity is provided on the inner surface of the end of the wearing part 20 in the boundary area, that is, on a certain section of a wearing surface. The end of the wearing surface is relatively thinner than the other parts by the coring section. Therefore, when the user wears the wearable device on the user's wrist, the wearing part, which is relatively thin, may be relatively more bent such that a gap is inhibited or prevented from being generated between the body 10 and the wearing part 20.

FIG. 18 is a view showing an example of an assembly order of the wearable device according to various embodiments of the present disclosure. An assembly process of the wearable device according to the present embodiment will be explained with reference to FIG. 18. Referring to FIG. 18, a battery bracket (inner bracket) for fixing electronic parts is further provided in the present embodiment. A structure by coupling the body housing and the battery bracket to each other is to guarantee assembly of a uni-body housing structure optimized to waterproofing. In addition, various electronic parts may be fixed to the battery bracket by assembling, attaching, fusing, riveting, screwing, and the like. The present embodiment may provide an assembly structure that excludes a screw boss. The battery bracket in which the electronic parts are modularized and the body housing are fixed by a hook and a gap between the curved window and the body housing is finished by a waterproof tape, so that the inner mounting space can be maximized and the waterproof performance can be maximized by excluding a screw boss. First, the battery is mounted in the battery bracket and a conductive or metal piece is fixed to the center of the rear surface of the battery. Next, a substrate assembly is assembled with the battery bracket and the display is fixed to the battery bracket. Finally, the body housing is assembled with the battery bracket assembly and a final assembly is completed.

FIG. 19 is a side view showing a wearable device according to various embodiments of the present disclosure, in which a body 30 and a wearing part 40 is decoupled from each other. FIG. 20 is a side view showing the body 30 and

20

the wearing part 40 which are coupled to each other according to various embodiments of the present disclosure. In explaining the configuration of the wearable device according to the present embodiment with reference to FIGS. 19 and 20, redundant explanation of the same elements as those of FIGS. 2 and 3 will be omitted and only differences will be explained.

In general, users' wrists have different curvatures when users wear wearable devices on their wrists. Since the respective curvatures of the users' wrists are different, a wearing sensation that each user can feel may be different. In particular, since woman's wrist is thinner than man's wrist, the wearable device cannot fit all of the users. However, since the wearable device according to the present embodiment has a structure in which the wearing part 40 is removable from the body 30 and the wearing part is changeable, users can select the wearing part to fit their respective body sizes.

The wearing part 40 of the wearable device according to the present embodiment of FIGS. 19 and 20 has a different curvature from the wrist curvature provided by the wearing part of the wearable device shown in FIGS. 2 and 3. The wearable device according to the present embodiment includes the wearing part 40 and the body 30 which can be coupled to or decoupled from the wearing part 40. The end of the wearing part 40 provides a varying curvature in the boundary area A where the body 30 and the wearing part 40 are coupled to each other, so that the wearable device can respond to various wrist curvatures.

The wearing part 40 includes a seating part 42 and a band part 41 and is configured to have a different curvature from the first curvature of the body (the curvature of the front surface of the body housing and the curved display) in the boundary area A between the seating part 42 and the band part 41. In addition, the curvature of a seating recess 33 on the side surface of the body is different from the first curvature in the boundary area A. When the curvature provided by the seating recess 33 and the seating part 42 in the boundary area A is smaller than the first curvature provided by the body 30, the wearable device makes a user who has a small wrist curvature feel good when the user wears it. When the curvature provided by the seating recess 33 and the seating part 42 in the boundary area A is greater than the first curvature provided by the body 30, the wearable device makes a user who has a large wrist curvature feel good when the user wears it.

In addition, the seating recess 33 of the body 30 includes a curvature of a top surface 33a and a curvature of a bottom surface 33b, and the curvature of the bottom surface 33b is smaller than the curvature of the top surface 33a in the boundary area A, so that the wearable device can respond to a user's wrist curvature.

As a result, the curvatures provided by the seating recess 33 and the seating part 42 of the wearing part do not need to be uniform and the wearable device can respond to various users' wrist curvatures by partially varying the curvature of the seating recess 33 or the curvature of the bottom surface 33b of the seating recess in the boundary area A.

The configuration of a wearing part according to various embodiments of the present disclosure will be explained with reference to FIGS. 21 to 24.

A wearing part shown in FIG. 21 includes first and second bands 51 and 52 and an area or a form 53 for arranging the first and second bands 51 and 52 as a single body. When a user wears the wearable device on user's wrist, the first and second bands 51 and 52 are arranged as a single body by the

clip **53**. The clip **53** is an accessory for clipping the first and second bands **51** and **52** and has a part opened. The first band **51** may be provided with a plurality of fastening holes in a lengthwise direction.

A wearing part shown in FIG. **22** includes first and second bands **61** and **62** and an area or a form **63** for arranging the first and second bands **61** and **62** as a single body. When a user wears the wearable device on user's wrist, the first and second bands **61** and **62** are arranged as a single body by the clip **63**. The clip **63** is an accessory for clipping the first and second bands **61** and **62** and has a part opened more than the clip **53** of FIG. **20**.

A wearing part shown in FIGS. **23A** and **B** includes first and second bands **71** and **72** and an area or a form **73** for arranging the first and second bands **71** and **72** as a single body. When a user wears the wearable device on user's wrist, the first and second bands **71** and **72** are restricted by each other by the clip **73**. The clip **73** may be an accessory that is integrally formed with the second band **72** and the first band **71** is arranged along with the second band **72** as a single body by the clip **73**. A fastening part **74** may be integrally formed with the end of the first band and a fastening protrusion of the fastening part **74** may be inserted into the hole of the second band, so that the first and second bands **71** and **72** are restricted by each other as a single body.

A wearing part shown in FIGS. **24A** and **B** may include first and second bands **81** and **82** and a clip **83** for arranging the first and second bands **81** and **82** as a single body. When a user wears the wearable device on user's wrist, the first and second bands **81** and **82** are restricted by each other by the clip **83**. The clip **83** is an accessory integrally formed with the second band **82** and the first band **81** is arranged along with the second band **82** as a single body by the clip **83**. A fastening part **84** is integrally formed with the end of the first band and a fastening protrusion of the fastening part **84** is inserted into the hole of the second band, so that the first and second bands **81** and **82** are restricted by each other as a single body.

The wearing part shown in FIGS. **21** to **26** may be configured in various colors and a wearing surface may be formed in an uneven shape (having a wave form when viewed in a cross section), thereby improving a sensation that the user may feel when wearing the wearable device.

FIG. **25** is a perspective view showing a wearable device which is coupled to a charging cradle according to various embodiments of the present disclosure. FIG. **26** is a perspective view showing a part of the charging cradle according to various embodiments of the present disclosure. FIG. **27** is a perspective view showing a part of the body housing of the wearable device according to various embodiments. Referring to FIGS. **25** to **27**, the wearable device **10** according to the present embodiment includes a holding structure to be held in the charging cradle **30** and maintain a connecting state stably. The holding structure may include a holding protrusion **310** formed inside an arm **300** of the charging cradle and a holding recess **133** formed on the body housing **12**. Although a single protrusion **310** and a single recess **133** are illustrated in the drawings, a pair of protrusions **310** and a pair of recesses **133** may be provided. By coupling the recess **133** and the protrusion **310**, the body **12** may be held in the charging cradle **30** and maintain a stable connecting status. Reference sign **c1** indicates a charging terminal provided on the bottom of the charging cradle **30**. A method for placing the wearable device **10** on the charging cradle **30** may include moving the wearable device **10** from top to bottom and coupling it to the charging cradle **30**.

According to various embodiments, at least part of the wearable device of the present disclosure may be implemented by using instructions stored in a computer-readable storage medium in the form of a programming module.

When the instructions are executed by one or more processors, the one or more processors may perform a function corresponding to the instructions. The computer-readable storage medium may be a memory, for example. At least part of the programming module may be implemented (e.g., executed) by using the processor. At least part of the programming module may include a module, a program, a routine, sets of instructions, a process, and the like for performing one or more functions.

Examples of the computer-readable recording medium include magnetic media such as hard disks, floppy disks and magnetic tapes, optical media such as Compact Disc Read Only Memories (CD-ROMs) and Digital Versatile Discs (DVDs), magneto-optical media such as floptical disks, and hardware devices such as (Read Only Memories (ROMs), Random Access Memories (RAMs) and flash memories that are especially configured to store and execute program commands (e.g., the programming module). Examples of the program commands include machine language codes created by a compiler, and high-level language codes that can be executed by a computer by using an interpreter. The above-described hardware devices may be configured to operate as one or more software modules for performing operations of the present disclosure, and vice versa.

A module or programming module of the present disclosure may include one or more of the above-described elements, may omit some elements, or may further include additional elements. The operations performed by the module, the programming module, or the other elements according to the present disclosure may be performed serially, in parallel, repeatedly, or heuristically. In addition, some operation may be performed in different order or may omitted, and an additional operation may be added.

While the disclosure has been shown and described with reference to certain embodiments thereof, it will be understood by those skilled in the art that various changes in form and details may be made therein without departing from the spirit and scope of the disclosure. Therefore, all differences including obvious variants thereof are to be construed as being within the scope and spirit of the present disclosure and will be construed as being included in the present disclosure.

What is claimed is:

1. A wearable device comprising:

a strap having a first end and a second end, the strap comprising an opening and a buckle formed at one of the first and second ends;

a buckle part configured to fasten the first and second ends of the strap to each other by binding the first and second ends; and

a body configured to be removably coupled to the opening by being fitted into the opening, wherein the body comprises a front surface and a rear surface,

wherein the body comprises a display on its front surface, the display having a substantially polygonal shape in a top view thereof, and wherein the body further comprises a biometric sensor disposed on its rear surface.

2. The wearable device of claim 1, wherein the substantially polygonal shape of the display is substantially rectangular.

3. The wearable device of claim 1, wherein the strap comprises a seating part from which the body is removable,

23

and the seating part being formed along a circumference of the opening, and wherein the seating part comprises at least one linear portion, and

wherein the body comprises a seating recess with which the seating part of the strap is configured to be mated.

4. The wearable device of claim 3, wherein the opening is opened in a vertical direction and has a rectangular shape having a thickness, and the body is removed from the opening by elastically deforming of the seating part of the strap.

5. The wearable device of claim 3, wherein the body comprises a curved body housing, and

wherein a front surface and a rear surface of the curved body housing have a first curvature and a second curvature, respectively, the first curvature being smaller than the second curvature.

6. The wearable device of claim 5, further comprising a biometric sensor,

wherein the display is curved and has a same curvature as the first curvature, and is mounted on the front surface of the curved body housing, and

wherein the rear surface of the curved body housing comprises a planar surface on a center area of the body and the biometric sensor is disposed on the planar surface.

7. The wearable device of claim 5, wherein the curved body housing has a horizontal direction width gradually reduced from a center toward the front surface, such that the body is decoupled by moving the body out from the opening by moving the body in a first removal direction and remains coupled when the body is moved in a direction opposite the first removal direction.

8. The wearable device of claim 5, further comprising a removal structure for selectively coupling and decoupling the curved body housing with respect to the opening by moving the curved body with respect to the opening along a second removal direction.

9. The wearable device of claim 8, wherein the removal structure comprises:

a seating recess extending along a circumference of a side surface of the curved body housing and having a curvature corresponding to a curvature of the opening; and

a seating part coupled to the seating recess to fix the curved body housing to the opening.

10. The wearable device of claim 9, wherein the curvature of corresponds to a curvature of an outer side surface of the curved body housing.

11. The wearable device of claim 9, wherein the seating recess comprises a first close contact surface which comprises a first top surface, a first intermediate surface, and a first bottom surface, and has a horizontal width of an exterior corresponding to the first bottom surface that is wider than a horizontal width of an exterior corresponding to the first top surface, and

wherein the seating part comprises a second close contact surface which is in close contact with the first close contact surface and comprises a second top surface, a second intermediate surface, and a second bottom surface, and has a horizontal width of an exterior corresponding to the second bottom surface that is wider than a horizontal width of an exterior corresponding to the second top surface, thereby providing the second removal direction.

24

12. The wearable device of claim 11, wherein at least one of the first and second bottom surfaces are one of horizontally planar surfaces and gently inclined surfaces.

13. The wearable device of claim 5, wherein at least one of the ends of the strap is configured to have a curvature that is different than the first curvature in a boundary area where the curved body housing and the strap are coupled to each other so that the wearable device responds to a wrist curvature of a human body.

14. The wearable device of claim 1, wherein the opening has a substantially polygonal shape in a top view.

15. A wearable device comprising:

a body housing;

a curved display disposed on a front surface of the body housing;

a curved battery layered under the curved display; and

a curved body comprising at least one substrate arranged between the curved battery and a rear surface of the body housing, wherein the curved display and the rear surface of the body housing have a first curvature and a second curvature, respectively, and the first curvature is smaller than the second curvature so that the curved body becomes gradually thinner from a center area toward a side area in a lengthwise direction.

16. The wearable device of claim 15, wherein the battery is configured to have a curvature that is equal to that of the curved display, and is disposed on a center area under the curved display to face the curved display.

17. The wearable device of claim 15, further comprising a conductive piece disposed on a center area of the rear surface of the battery to stop an increase in a volume of the battery.

18. A wearable device comprising:

a body housing;

a curved display disposed on a front surface of the body housing;

a curved battery layered under the curved display; and

a curved body comprising at least one substrate arranged between the curved battery and a rear surface of the body housing,

wherein the at least one substrate comprises:

at least one rigid substrate placed horizontally or slantingly; and

at least one flexible substrate connected with the at least one rigid substrate, and the substrates form a segmental structure, and

wherein the at least one substrate includes a first substrate that is disposed on a center area between the rear surface of the body housing and a rear surface of the battery, and

wherein a first sensor is disposed on a bottom surface of the first substrate, and the first sensor has a sensor interface exposed from the center area of the rear surface of the body housing.

19. The wearable device of claim 18, wherein the rear surface of the body housing further comprises a protrusion that encloses a circumference of the sensor interface.

20. The wearable device of claim 18, wherein the curved display comprises:

a flexible display having a first curvature; and

a rigid or flexible layer integrally formed on the flexible display with a same curvature.
