**N-(PYRIDIN-2-YL)PYRIMIDIN-4-AMINE  
DERIVATIVES CONTAINING A  
SULFOXIMINE GROUP**

The present invention relates to disubstituted N-(pyridin-2-yl)pyrimidin-4-amine derivatives containing a sulfoximine group of general formula (I) as described and defined herein, and methods for their preparation, their use for the treatment and/or prophylaxis of disorders, in particular of hyper-proliferative disorders and/or virally induced infectious diseases and/or of cardiovascular diseases. The invention further relates to intermediate compounds useful in the preparation of said compounds of general formula (I).

The family of cyclin-dependent kinase (CDK) proteins consists of members that are key regulators of the cell division cycle (cell cycle CDK's), that are involved in regulation of gene transcription (transcriptional CDK's), and of members with other functions. CDKs require for activation the association with a regulatory cyclin subunit. The cell cycle CDKs CDK1/cyclin B, CDK2/cyclin A, CDK2/cyclinE, CDK4/cyclinD, and CDK6/cyclinD get activated in a sequential order to drive a cell into and through the cell division cycle. The transcriptional CDKs CDK9/cyclin T and CDK7/cyclin H regulate the activity of RNA polymerase II via phosphorylation of the carboxy-terminal domain (CTD). Positive transcription factor b (P-TEFb) is a heterodimer of CDK9 and one of four cyclin partners, cyclin T1, cyclin K, cyclin T2a or T2b.

Whereas CDK9 (NCBI GenBank Gene ID 1025) is exclusively involved in transcriptional regulation, CDK7 in addition participates in cell cycle regulation as CDK-activating kinase (CAK).

Transcription of genes by RNA polymerase II is initiated by assembly of the pre-initiation complex at the promoter region and phosphorylation of Ser 5 and Ser 7 of the CTD by CDK7/cyclin H. For a major fraction of genes RNA polymerase II stops mRNA transcription after it moved 20-40 nucleotides along the DNA template. This promoter-proximal pausing of RNA polymerase II is mediated by negative elongation factors and is recognized as a major control mechanism to regulate expression of rapidly induced genes in response to a variety of stimuli (Cho et al., *Cell Cycle* 9, 1697, 2010). P-TEFb is crucially involved in overcoming promoter-proximal pausing of RNA polymerase II and transition into a productive elongation state by phosphorylation of Ser 2 of the CTD as well as by phosphorylation and inactivation of negative elongation factors.

Activity of P-TEFb itself is regulated by several mechanisms. About half of cellular P-TEFb exists in an inactive complex with 7SK small nuclear RNA (7SK snRNA), La-related protein 7 (LARP7/PIP7S) and hexamethylene bis-acetamide inducible proteins 1/2 (HEXIM1/2, He et al., *Mol Cell* 29, 588, 2008). The remaining half of P-TEFb exists in an active complex containing the bromodomain protein Brd4 (Yang et al., *Mol Cell* 19, 535, 2005). Brd4 recruits P-TEFb through interaction with acetylated histones to chromatin areas primed for gene transcription. Through alternately interacting with its positive and negative regulators, P-TEFb is maintained in a functional equilibrium: P-TEFb bound to the 7SK snRNA complex represents a reservoir from which active P-TEFb can be released on demand of cellular transcription and cell proliferation (Zhou & Yik, *Microbiol Mol Biol Rev* 70, 646, 2006). Furthermore, the activity of P-TEFb is regulated by posttranslational modifications including phosphorylation/de-phosphorylation, ubiquitination, and acetylation (reviewed in Cho et al., *Cell Cycle* 9, 1697, 2010).

Deregulated activity of CDK9 kinase activity of the P-TEFb heterodimer is associated with a variety of human pathological settings such as hyper-proliferative diseases (e.g. cancer), virally induced infectious diseases or cardiovascular diseases:

Cancer is regarded as a hyper-proliferative disorder mediated by a disbalance of proliferation and cell death (apoptosis). High levels of anti-apoptotic Bcl-2-family proteins are found in various human tumors and account for prolonged survival of tumor cells and therapy resistance. Inhibition of P-TEFb kinase activity was shown to reduce transcriptional activity of RNA polymerase II leading to a decline of short-lived anti-apoptotic proteins, especially Mcl-1 and XIAP, reinstalling the ability of tumor cells to undergo apoptosis. A number of other proteins associated with the transformed tumor phenotype (such as Myc, NF-kB responsive gene transcripts, mitotic kinases) are either short-lived proteins or are encoded by short-lived transcripts which are sensitive to reduced RNA polymerase II activity mediated by P-TEFb inhibition (reviewed in Wang & Fischer, *Trends Pharmacol Sci* 29, 302, 2008).

Many viruses rely on the transcriptional machinery of the host cell for the transcription of their own genome. In case of HIV-1, RNA polymerase II gets recruited to the promoter region within the viral LTR's. The viral transcription activator (Tat) protein binds to nascent viral transcripts and overcomes promoter-proximal RNA polymerase II pausing by recruitment of P-TEFb which in turn promotes transcriptional elongation. Furthermore, the Tat protein increases the fraction of active P-TEFb by replacement of the P-TEFb inhibitory proteins HEXIM1/2 within the 7SK snRNA complex. Recent data have shown that inhibition of the kinase activity of P-TEFb is sufficient to block HIV-1 replication at kinase inhibitor concentrations that are not cytotoxic to the host cells (reviewed in Wang & Fischer, *Trends Pharmacol Sci* 29, 302, 2008). Similarly, recruitment of P-TEFb by viral proteins has been reported for other viruses such as B-cell cancer-associated Epstein-Barr virus, where the nuclear antigen EBNA2 protein interacts with P-TEFb (Bark-Jones et al., *Oncogene*, 25, 1775, 2006), and the human T-lymphotropic virus type 1 (HTLV-1), where the transcriptional activator Tax recruits P-TEFb (Zhou et al., *J Virol*. 80, 4781, 2006).

Cardiac hypertrophy, the heart's adaptive response to mechanical overload and pressure (hemodynamic stress e.g. hypertension, myocardial infarction), can lead, on a long term, to heart failure and death. Cardiac hypertrophy was shown to be associated with increased transcriptional activity and RNA polymerase II CTD phosphorylation in cardiac muscle cells. P-TEFb was found to be activated by dissociation from the inactive 7SK snRNA/HEXIM1/2 complex. These findings suggest pharmacological inhibition of P-TEFb kinase activity as a therapeutic approach to treat cardiac hypertrophy (reviewed in Dey et al., *Cell Cycle* 6, 1856, 2007).

In summary, multiple lines of evidence suggest that selective inhibition of the CDK9 kinase activity of the P-TEFb heterodimer (=CDK9 and one of four cyclin partners, cyclin T1, cyclin K, cyclin T2a or T2b) represents an innovative approach for the treatment of diseases such as cancer, viral diseases, and/or diseases of the heart. CDK9 belongs to a family of at least 13 closely related kinases of which the subgroup of the cell cycle CDK's fulfills multiple roles in regulation of cell proliferation. Thus, co-inhibition of cell cycle CDKs (e.g. CDK1/cyclin B, CDK2/cyclin A, CDK2/cyclinE, CDK4/cyclinD, CDK6/cyclinD) and of CDK9, is expected to impact normal proliferating tissues

such as intestinal mucosa, lymphatic and hematopoietic organs, and reproductive organs. To maximize the therapeutic margin of CDK9 kinase inhibitors, molecules with high selectivity towards CDK9 are required.

CDK inhibitors in general as well as CDK9 inhibitors are described in a number of different publications: WO2008129070 and WO2008129071 both describe 2,4 disubstituted aminopyrimidines as CDK inhibitors in general. It is also asserted that some of these compounds may act as selective CDK9 inhibitors (WO2008129070) and as CDK5 inhibitors (WO2008129071), respectively, but no specific CDK9 IC<sub>50</sub> (WO2008129070) or CDK5 IC<sub>50</sub> (WO2008129071) data is presented. These compounds do not contain a fluoro atom in 5-position of the pyrimidine core.

WO2008129080 discloses 4,6 disubstituted aminopyrimidines and demonstrates that these compounds show an inhibitory effect on the protein kinase activity of various protein kinases, such as CDK1, CDK2, CDK4, CDK5, CDK6 and CDK9, with a preference for CDK9 inhibition (example 80).

WO2005026129 discloses 4,6 disubstituted aminopyrimidines and demonstrates that these compounds show an inhibitory effect on the protein kinase activity of various protein kinases, in particular CDK2, CDK4, and CDK9.

EP1218360 B1, which corresponds to US2004116388A1, U.S. Pat. No. 7,074,789B2 and WO2001025220A1, describes triazine derivatives as kinase inhibitors, but does not disclose potent or selective CDK9 inhibitors.

WO2008079933 discloses aminopyridine and aminopyrimidine derivatives and their use as CDK1, CDK2, CDK3, CDK4, CDK5, CDK6, CDK7, CDK8 or CDK9 inhibitors.

WO2011012661 describes aminopyridine derivatives useful as CDK inhibitors.

WO2011026917 discloses carboxamides derived from substituted 4-phenylpyridine-2-amines as inhibitors of CDK9.

WO2012066065 discloses phenyl-heteroaryl amines as inhibitors of CDK9. A selectivity towards CDK9 over other CDK isoforms is preferred, however disclosure of CDK-inhibition data is confined to CDK 9. No bicyclic ring systems are disclosed attached to the C4 position of the pyrimidine core. Within the group attached to C4 of the pyrimidine core, alkoxy phenyls can be regarded as encompassed, but there is no suggestion for a specific substitution pattern characterised by a fluoro atom attached to C5 of the pyrimidine ring, and an aniline at C2 of the pyrimidine, featuring a substituted sulfonyl-methylene group in meta position. Compounds shown in the examples typically feature a substituted cycloalkyl group as R<sup>1</sup> but no phenyl.

WO2012066070 discloses 3-(aminoaryl)-pyridine compounds as inhibitors of CDK9. The biaryl core mandatorily consists of two heteroaromatic rings.

WO2012101062 discloses substituted bi-heteroaryl compounds featuring a 2-aminopyridine core as inhibitors of CDK9. The biaryl core mandatorily consists of two heteroaromatic rings.

WO2012101063 discloses carboxamides derived from substituted 4-(heteroaryl)-pyridine-2-amines as inhibitors of CDK9.

Despite the fact that various inhibitors of CDKs are known, there remains a need for selective CDK9 inhibitors to be used for the treatment of diseases such as hyperproliferative diseases, viral diseases, and/or diseases of the heart, which offer one or more advantages over the compounds known from prior art, such as:

- improved activity and/or efficacy
- beneficial kinase selectivity profile according to the respective therapeutic need
- improved side effect profile, such as fewer undesired side effects, lower intensity of side effects, or reduced (cyto)toxicity, e.g. via reduced inhibition of Carbonic anhydrase
- improved physicochemical properties, such as solubility in water body fluids, and aqueous formulations, e.g. for intravenous administration
- improved pharmacokinetic properties, allowing e.g. for dose reduction or an easier dosing scheme
- easier drug substance manufacturing e.g. by shorter synthetic routes or easier purification.

A particular object of the invention is to provide CDK9 kinase inhibitors which, compared to the compounds known from prior art, show an increased selectivity for CDK9/Cyclin T1 as compared to CDK2/Cyclin E.

Another object of the invention is to provide CDK9 kinase inhibitors which show an increased potency to inhibit CDK9 activity (demonstrated by a lower  $IC_{50}$  value for CDK9/Cyclin T1) compared to the compounds known from prior art.

Another object of the invention is to provide CDK9 kinase inhibitors which show an increased potency to inhibit CDK9 activity at high ATP concentrations compared to the compounds known from prior art.

Another object of the invention is to provide CDK9 kinase inhibitors, which show an improved anti-proliferative activity in tumor cell lines such as HeLa compared to the compounds known from prior art.

Further, it is also an object of the present invention to provide CDK9 kinase inhibitors, which, compared to the compounds known from prior art, are highly selective for CDK9/Cyclin T1 as compared to CDK2/Cyclin E, and/or which show an increased potency to inhibit CDK9 activity and/or which show an improved anti-proliferative activity in tumor cell lines such as HeLa and/or which show an increased potency to inhibit CDK9 activity at high ATP concentrations compared to the compounds known from prior art.

and the enantiomers, diastereomers, salts, solvates or salts of solvates thereof.

Compounds according to the invention are the compounds of the formula (I) and the salts, solvates and solvates of the salts thereof, the compounds of the hereinafter recited

formula which are encompassed by formula (I) and the salts, solvates and solvates of the salts thereof, and the compounds which are encompassed by formula (I) and are mentioned hereinafter as exemplary embodiments and the salts, solvates and solvates of the salts thereof, where the compounds which are encompassed by formula (I) and are mentioned hereinafter are not already salts, solvates and solvates of the salts.

The compounds according to the invention may, depending on their structure, exist in stereoisomeric forms (enantiomers, diastereomers). The invention therefore relates to the enantiomers or diastereomers and respective mixtures thereof. The stereoisomerically pure constituents can be isolated in a known manner from such mixtures of enantiomers and/or diastereomers.

If the compounds according to the invention can be in tautomeric forms, the present invention encompasses all tautomeric forms.

Further, the compounds of the present invention can exist in free form, e.g. as a free base, or as a free acid, or as a zwitterion, or can exist in the form of a salt. Said salt may be any salt, either an organic or inorganic addition salt, particularly any physiologically acceptable organic or inorganic addition salt, customarily used in pharmacy.

Salts which are preferred for the purposes of the present invention are physiologically acceptable salts of the compounds according to the invention. However, salts which are not suitable for pharmaceutical applications per se, but which, for example, can be used for the isolation or purification of the compounds according to the invention, are also comprised.

The term "physiologically acceptable salt" refers to a relatively non-toxic, inorganic or organic acid addition salt of a compound of the present invention, for example, see S. M. Berge, et al. "Pharmaceutical Salts," J. Pharm. Sci. 1977, 66, 1-19.

Physiologically acceptable salts of the compounds according to the invention encompass acid addition salts of mineral acids, carboxylic acids and sulfonic acids, for example salts of hydrochloric acid, hydrobromic acid, hydroiodic, sulfuric acid, bisulfuric acid, phosphoric acid, nitric acid or with an organic acid, such as formic, acetic, acetoacetic, pyruvic, trifluoroacetic, propionic, butyric, hexanoic, heptanoic, undecanoic, lauric, benzoic, salicylic, 2-(4-hydroxybenzoyl)-benzoic, camphoric, cinnamic, cyclopentanepropionic, digluconic, 3-hydroxy-2-naphthoic, nicotinic, pamoic, pectinic, persulfuric, 3-phenylpropionic, picric, pivalic, 2-hydroxyethanesulfonate, itaconic, sulfamic, trifluoromethanesulfonic, dodecylsulfuric, ethansulfonic, benzenesulfonic, para-toluenesulfonic, methansulfonic, 2-naphthalenesulfonic, naphthalenedisulfonic, camphorsulfonic acid, citric, tartaric, stearic, lactic, oxalic, malonic, succinic, malic, adipic, alginic, maleic, fumaric, D-gluconic, mandelic, ascorbic, glucoheptanoic, glycerophosphoric, aspartic, sulfosalicylic, hemisulfuric, or thiocyanic acid, for example.

Physiologically acceptable salts of the compounds according to the invention also comprise salts of conventional bases, such as, by way of example and by preference, alkali metal salts (for example sodium and potassium salts), alkaline earth metal salts (for example calcium and magnesium salts) and ammonium salts derived from ammonia or organic amines with 1 to 16 C atoms, such as, by way of example and by preference, ethylamine, diethylamine, triethylamine, ethyldiisopropylamine, monoethanolamine, diethanolamine, triethanolamine, dicyclohexylamine, dimethylaminoethanol, procaine, dibenzylamine, N-methylmor-

pholine, arginine, lysine, ethylenediamine, N-methylpiperidine, N-methylglucamine, dimethylglucamine, ethylglucamine, 1,6-hexadiazine, glucosamine, sarcosine, serinol, tris(hydroxymethyl)aminomethane, aminopropane diol, Sovak base, and 1-amino-2,3,4-butanetriol. Additionally, the compounds according to the invention may form salts with a quaternary ammonium ion obtainable e.g. by quaternisation of a basic nitrogen containing group with agents like lower alkylhalides such as methyl-, ethyl-, propyl-, and butylchlorides, -bromides and -iodides; dialkylsulfates like dimethyl-, diethyl-, dibutyl- and diamylsulfates, long chain halides such as decyl-, lauryl-, myristyl- and stearylchlorides, -bromides and -iodides, aralkylhalides like benzyl- and phenethylbromides and others. Examples of suitable quaternary ammonium ions are tetramethylammonium, tetraethylammonium, tetra(n-propyl)ammonium, tetra(n-butyl)ammonium, or N-benzyl-N,N,N-trimethylammonium.

Hydrates are a special form of solvates in which the coordination takes place with water. Hydrates are preferred as solvates within the scope of the present invention.

The invention also includes all suitable isotopic variations of a compound of the invention. An isotopic variation of a compound of the invention is defined as one in which at least one atom is replaced by an atom having the same atomic number but an atomic mass different from the atomic mass usually or predominantly found in nature. Examples of isotopes that can be incorporated into a compound of the invention include isotopes of hydrogen, carbon, nitrogen, oxygen, phosphorus, sulfur, fluorine, chlorine, bromine and iodine, such as  $^2\text{H}$  (deuterium),  $^3\text{H}$  (tritium),  $^{13}\text{C}$ ,  $^{14}\text{C}$ ,  $^{15}\text{N}$ ,  $^{17}\text{O}$ ,  $^{18}\text{O}$ ,  $^{32}\text{P}$ ,  $^{33}\text{P}$ ,  $^{33}\text{S}$ ,  $^{34}\text{S}$ ,  $^{35}\text{S}$ ,  $^{36}\text{S}$ ,  $^{18}\text{F}$ ,  $^{36}\text{Cl}$ ,  $^{82}\text{Br}$ ,  $^{123}\text{I}$ ,  $^{124}\text{I}$ ,  $^{129}\text{I}$ , and  $^{131}\text{I}$ , respectively. Certain isotopic variations of a compound of the invention, for example, those in which one or more radioactive isotopes such as  $^3\text{H}$  or  $^{14}\text{C}$  are incorporated, are useful in drug and/or substrate tissue distribution studies. Tritiated and carbon-14, i.e.,  $^{14}\text{C}$ , isotopes are particularly preferred for their ease of preparation and detectability. Further, substitution with isotopes such as deuterium may afford certain therapeutic advantages resulting from greater metabolic stability, for example, increased in vivo half-life or reduced dosage requirements and hence may be preferred in some circumstances. Isotopic variations of a compound of the invention can generally be prepared by conventional procedures known by a person skilled in the art such as by the illustrative methods or by the preparations described in the examples hereafter using appropriate isotopic variations of suitable reagents.

In addition, the present invention also encompasses prodrugs of the compounds according to the invention. The compounds according to the invention show a valuable pharmacological and pharmacokinetic spectrum of action which could not have been predicted.

They are therefore suitable for use as medicaments for the treatment and/or prophylaxis of disorders in humans and animals.

Within the scope of the present invention, the term "treatment" includes prophylaxis.

The pharmaceutical activity of the compounds according to the invention can be explained by their action as inhibitors of CDK9. Thus, the compounds according to the general formula (I) as well as the enantiomers, diastereomers, salts, solvates and salts of solvates thereof are used as inhibitors for CDK9. Furthermore, the compounds according to the invention show a particularly high potency (demonstrated by a low  $IC_{50}$  value in the CDK9/CycT1 assay) for inhibiting CDK9 activity.

In context of the present invention, the  $IC_{50}$  value with respect to CDK9 can be determined by the methods described in the method section below. Preferably, it is determined according to Method 1a. ("CDK9/CycT1 kinase assay") described in the Materials and Method section below.

Surprisingly it turned out that the compounds according to the general formula (I) as well as the enantiomers, diastereomers, salts, solvates and salts of solvates thereof selectively inhibit CDK9 in comparison to other cyclin-dependent protein kinases, preferably in comparison to CDK2. Thus, the compounds according to the general formula (I) as well as pharmaceutically acceptable salts thereof are preferably used as selective inhibitors for CDK9.

Compounds of the present invention according to general formula (I) show a significantly stronger CDK9 than CDK2 inhibition.

In context of the present invention, the  $IC_{50}$  value with respect to CDK2 can be determined by the methods described in the method section below. Preferably, it is determined according to Method 2. ("CDK2/CycE kinase assay") described in the Materials and Method section below.

Further, as compared to the CDK9 inhibitors described in the prior art, preferred compounds of the present invention according to general formula (I) show a surprisingly high potency for inhibiting CDK9 activity at high ATP concentrations, which is demonstrated by their low  $IC_{50}$  value in the CDK9/CycT1 high ATP kinase assay. Thus, these compounds have a lower probability to be competed out of the ATP-binding pocket of CDK9/CycT1 kinase due to the high intracellular ATP concentration (R. Copeland et al., Nature Reviews Drug Discovery 2006, 5, 730-739). According to this property the compounds of the present invention are particularly able to inhibit CDK9/CycT1 within cells for a longer period of time as compared to classical ATP competitive kinase inhibitors. This increases the anti-tumor cell efficacy at pharmacokinetic clearance-mediated declining serum concentrations of the inhibitor after dosing of a patient or an animal.

In context of the present invention, the  $IC_{50}$  value with respect to CDK9 at high ATP concentrations can be determined by the methods described in the method section below. Preferably, it is determined according to Method 1b ("CDK9/CycT1 high ATP kinase assay") as described in the Materials and Method section below.

Further, preferred compounds of the present invention according to formula (I) show an improved anti-proliferative activity in tumor cell lines such as HeLa compared to the CDK9 inhibitors described in the prior art. In context of the

present invention, the anti-proliferative activity in tumor cell lines such as HeLa is preferably determined according to Method 3. ("Proliferation Assay") as described in the Materials and Method section below.

Further, preferred compounds of the present invention according to formula (I) surprisingly show an increased solubility in water at pH 6.5 compared to the compounds described in the prior art.

In context of the present invention the solubility in water at pH 6.5 is preferably determined according to Method 4a. ("Equilibrium Shake Flask Solubility Assay, Thermodynamic solubility in water") as described in the Materials and Method section below.

Further, preferred compounds of the present invention according to formula (I) are characterized by improved pharmacokinetic properties, such as an increased apparent Caco-2 permeability ( $P_{app}$  A-B) across Caco-2 cell monolayers, compared to the compounds known from the prior art.

Further, preferred compounds of the present invention according to formula (I) are characterized by improved pharmacokinetic properties, such as a decreased efflux ratio ( $\text{efflux ratio} = P_{app} B-A / P_{app} A-B$ ) from the basal to apical compartment across Caco-2 cell monolayers, compared to the compounds known from the prior art.

In context of the present invention, the apparent Caco-2 permeability values from the basal to apical compartment ( $P_{app} A-B$ ) or the efflux ratio (defined as the ratio  $((P_{app} B-A) / (P_{app} A-B))$ ) are preferably determined according to Method 5. ("Caco-2 Permeation Assay") described in the Materials and Method section below.

Further, preferred compounds of the present invention according to formula (I) show no significant inhibition of carbonic anhydrase-1 or -2 ( $IC_{50}$  values of more than 10  $\mu\text{M}$ ) and therefore show an improved side effect profile as compared to those CDK inhibitors described in the prior art containing a sulfonamide group, which inhibit carbonic anhydrase-1 or -2. In context of the present invention, the carbonic anhydrase-1 and -2 inhibition is preferably determined according to Method 6. ("Carbonic anhydrase Assay") described in the Materials and Method section below.

A further subject matter of the present invention is the use of the compounds of general formula (I) according to the invention for the treatment and/or prophylaxis of disorders, preferably of disorders relating to or mediated by CDK9 activity, in particular of hyper-proliferative disorders, virally induced infectious diseases and/or of cardiovascular diseases, more preferably of hyper-proliferative disorders.

#### Materials and Methods:

The percentage data in the following tests and examples are percentages by weight unless otherwise indicated; parts are parts by weight. Solvent ratios, dilution ratios and concentration data of liquid/liquid solutions are in each case based on volume.

Examples were tested in selected biological assays one or more times. When tested more than once, data are reported as either average values or as median values, wherein

the average value, also referred to as the arithmetic mean value, represents the sum of the values obtained divided by the number of times tested, and

the median value represents the middle number of the group of values when ranked in ascending or descending order. If the number of values in the data set is odd, the median is the middle value. If the number of values in the data set is even, the median is the arithmetic mean of the two middle values.

Examples were synthesized one or more times. When synthesized more than once, data from biological assays represent average values or median values calculated utilizing data sets obtained from testing of one or more synthetic batch.

The in vitro pharmacological properties of the compounds can be determined according to the following assays and methods.

#### 1a. CDK9/CycT1 Kinase Assay:

CDK9/CycT1-inhibitory activity of compounds of the present invention was quantified employing the CDK9/CycT1 TR-FRET assay as described in the following paragraphs:

Recombinant full-length His-tagged human CDK9 and CycT1, expressed in insect cells and purified by Ni-NTA affinity chromatography, were purchased from Invitrogen (Cat. No PV4131). As substrate for the kinase reaction biotinylated peptide biotin-Ttds-YISPLKSPYKISEG (C-terminus in amid form) was used which can be purchased e.g. form the company JERINI Peptide Technologies (Berlin, Germany) For the assay 50 nl of a 100 fold concentrated solution of the test compound in DMSO was pipetted into a black low volume 384 well microtiter plate (Greiner Bio-One, Frickenhausen, Germany), 2  $\mu$ l of a solution of CDK9/CycT1 in aqueous assay buffer [50 mM Tris/HCl pH 8.0, 10 mM MgCl<sub>2</sub>, 1.0 mM dithiothreitol, 0.1 mM sodium ortho-vanadate, 0.01% (v/v) Nonidet-P40 (Sigma)] were added and the mixture was incubated for 15 min at 22° C. to allow pre-binding of the test compounds to the enzyme before the start of the kinase reaction. Then the kinase reaction was started by the addition of 3  $\mu$ l of a solution of adenosine-tri-phosphate (ATP, 16.7  $\mu$ M=>final conc. in the 5  $\mu$ l assay volume is 10  $\mu$ M) and substrate (1.67  $\mu$ M=>final conc. in the 5  $\mu$ l assay volume is 1  $\mu$ M) in assay buffer and the resulting mixture was incubated for a reaction time of 25 min at 22° C. The concentration of CDK9/CycT1 was adjusted depending of the activity of the enzyme lot and was chosen appropriate to have the assay in the linear range, typical concentrations were in the range of 1  $\mu$ g/ml. The reaction was stopped by the addition of 5  $\mu$ l of a solution of TR-FRET detection reagents (0.2  $\mu$ M streptavidine-XL665 [Cisbio Bioassays, Codolet, France] and 1 nM anti-RB (pSer807/pSer811)-antibody from BD Pharmingen

[#558389] and 1.2 nM LANCE EU-W1024 labeled anti-mouse IgG antibody [Perkin-Elmer, product no. AD0077]) in an aqueous EDTA-solution (100 mM EDTA, 0.2% (w/v) bovine serum albumin in 100 mM HEPES/NaOH pH 7.0).

The resulting mixture was incubated 1 h at 22° C. to allow the formation of complex between the phosphorylated biotinylated peptide and the detection reagents. Subsequently the amount of phosphorylated substrate was evaluated by measurement of the resonance energy transfer from the Eu-chelate to the streptavidine-XL. Therefore, the fluorescence emissions at 620 nm and 665 nm after excitation at 350 nm was measured in a HTRF reader, e.g. a Rubystar (BMG Labtechnologies, Offenburg, Germany) or a Viewlux (Perkin-Elmer). The ratio of the emissions at 665 nm and at 622 nm was taken as the measure for the amount of phosphorylated substrate. The data were normalised (enzyme reaction without inhibitor=0% inhibition, all other assay components but no enzyme=100% inhibition). Usually the test compounds were tested on the same microtiterplate in 11 different concentrations in the range of 20  $\mu$ M to 0.1 nM (20  $\mu$ M, 5.9  $\mu$ M, 1.7  $\mu$ M, 0.51  $\mu$ M, 0.15  $\mu$ M, 44 nM, 13 nM, 3.8 nM, 1.1 nM, 0.33 nM and 0.1 nM, the dilution series prepared separately before the assay on the level of the 100 fold concentrated solutions in DMSO by serial 1:3.4 dilutions) in duplicate values for each concentration and IC<sub>50</sub> values were calculated by a 4 parameter fit using an inhouse software.

### 3. Proliferation Assay:

Cultivated tumour cells (HeLa, human cervical tumour cells, ATCC CCL-2; NCI-H460, human non-small cell lung carcinoma cells, ATCC HTB-177; A2780, human ovarian carcinoma cells, ECACC #93112519; DU 145, hormone-independent human prostate carcinoma cells, ATCC HTB-81; HeLa-MaTu-ADR, multidrug-resistant human cervical carcinoma cells, EPO-GmbH Berlin; Caco-2, human colorectal carcinoma cells, ATCC HTB-37; B16F<sub>10</sub>, mouse melanoma cells, ATCC CRL-6475) were plated at a density of 5,000 cells/well (DU145, HeLa-MaTu-ADR), 3,000 cells/well (NCI-H460, HeLa), 2,500 cells/well (A2780), 1,500 cells/well (Caco-2), or 1,000 cells/well (B16F<sub>10</sub>) in a 96-well multititer plate in 200  $\mu\text{L}$  of their respective growth medium supplemented 10% fetal calf serum. After 24 hours, the cells of one plate (zero-point plate) were stained with crystal violet (see below), while the medium of the other plates was replaced by fresh culture medium (200  $\mu\text{L}$ ), to which the test substances were added in various concentrations (0  $\mu\text{M}$ , as well as in the range of 0.001-10  $\mu\text{M}$ ; the final concentration of the solvent dimethyl sulfoxide was 0.5%). The cells were incubated for 4 days in the presence of test substances. Cell proliferation was determined by staining the cells with crystal violet: the cells were fixed by adding 20  $\mu\text{L}$ /measuring point of an 11% glutaric aldehyde solution for 15 minutes at room temperature. After three washing cycles of the fixed cells with water, the plates were dried at room temperature. The cells were stained by adding 100  $\mu\text{L}$ /measuring point of a 0.1% crystal violet solution (pH 3.0). After three washing cycles of the stained cells with water, the plates were dried at room temperature. The dye was dissolved by adding 100  $\mu\text{L}$ /measuring point of a 10% acetic acid solution. The extinction was determined by photometry at a wavelength of 595 nm. The change of cell number, in percent, was calculated by normalization of the measured values to the extinction values of the zero-point plate (=0%) and the extinction of the untreated (0  $\mu\text{M}$ ) cells (=100%). The  $\text{IC}_{50}$  values (inhibitory concentration at 50% of maximal effect) were determined by means of a 4 parameter fit.

Non-adherent MOLM-13 human acute myeloid leukemia cells (DSMZ ACC 554) were seeded at a density of 5,000 cells/well in a 96-well multititer plate in 100  $\mu\text{L}$  of growth medium supplemented 10% fetal calf serum. After 24 hours, cell viability of one plate (zero-point plate) was determined with the Cell Titre-Glo Luminescent Cell Viability Assay (Promega), while 50  $\mu\text{L}$  of test compound containing medium was added to the wells of the other plates (final

concentrations in the range of 0.001-10  $\mu\text{M}$  and DMSO controls; the final concentration of the solvent dimethyl sulfoxide was 0.5%). Cell viability was assessed after 72-hour exposure with the Cell Titre-Glo Luminescent Cell Viability Assay (Promega).  $\text{IC}_{50}$  values (inhibitory concentration at 50% of maximal effect) were determined by means of a 4 parameter fit on measurement data which were normalized to vehicle (DMSO) treated cells (=100%) and measurement readings taken immediately before compound exposure (=0%).

### 4. Equilibrium Shake Flask Solubility Assay:

#### 4a) Thermodynamic Solubility in Water

The thermodynamic solubility of compounds in water was determined by an equilibrium shake flask method (see for example: E. H. Kerns, L. Di: Drug-like Properties: Concepts, Structure Design and Methods, 276-286, Burlington, Mass., Academic Press, 2008). A saturated solution of the drug was prepared and the solution was mixed for 24 h to ensure that equilibrium was reached. The solution was centrifuged to remove the insoluble fraction and the concentration of the compound in solution was determined using a standard calibration curve. To prepare the sample, 2 mg solid compound was weighed in a 4 mL glass vial. 1 mL phosphate buffer pH 6.5 was added. The suspension was stirred for 24 hrs at room temperature. The solution was centrifuged afterwards. To prepare the sample for the standard calibration, 2 mg solid sample was dissolved in 30 mL acetonitrile. After sonification the solution was diluted with water to 50 mL. Sample and standards were quantified by HPLC with UV-detection. For each sample two injection volumes (5 and 50  $\mu\text{L}$ ) in triplicates were made. Three injection volumes (5  $\mu\text{L}$ , 10 ml and 20 ml) were made for the standard.

#### 4b) Thermodynamic Solubility in Citrate Buffer pH 4

Thermodynamic solubility was determined by an equilibrium shake flask method [Literature: Edward H. Kerns and Li Di (2008) Solubility Methods in: Drug-like Properties: Concepts, Structure Design and Methods, p 276-286. Burlington, Mass.: Academic Press].

A saturated solution of the drug was prepared and the solution was mixed for 24 h to ensure that equilibrium has been reached. The solution was centrifuged to remove the insoluble fraction and the concentration of the compound in solution was determined using a standard calibration curve.

To prepare the sample, 1.5 mg solid compound was weighed in a 4 ml glass vial. 1 ml Citrate buffer pH 4 was added. The suspension was put on a stirrer and mixed for 24 hrs at room temperature. The solution was centrifuged afterwards. To prepare the sample for the standard calibration, 0.6 mg solid sample was dissolved in 19 ml acetonitrile.

5. Caco-2 Permeation Assay:

Caco-2 cells (purchased from DSMZ Braunschweig, Germany) were seeded at a density of  $4.5 \times 10^4$  cells per well on 24 well insert plates, 0.4  $\mu$ m pore size, and grown for 15 days in DMEM medium supplemented with 10% fetal bovine serum, 1% GlutaMAX (100x, GIBCO), 100 U/mL penicillin, 100  $\mu$ g/mL streptomycin (GIBCO) and 1% non essential amino acids (100x). Cells were maintained at 37° C. in a humidified 5% CO<sub>2</sub> atmosphere. Medium was changed every 2-3 day. Before running the permeation assay, the culture medium was replaced by a FCS-free hepes-carbonate transport buffer (pH 7.2). For assessment of monolayer integrity the transepithelial electrical resistance (TEER) was measured. Test compounds were predissolved in DMSO and added either to the apical or basolateral compartment in final concentration of 2  $\mu$ M in transport buffer. Before and after 2 h incubation at 37° C. samples were taken from both compartments. Analysis of compound content was done after precipitation with methanol by LC/MS/MS analysis. Permeability (Papp) was calculated in the apical to basolateral (A→B) and basolateral to apical (B→A) directions. The apparent permeability was calculated using following equation:

$$P_{app} = (V_r/P_o)(1/S)(P_2/t)$$

Where  $V_r$  is the volume of medium in the receiver chamber,  $P_o$  is the measured peak area or height of the test drug in the donor chamber at  $t=0$ ,  $S$  the surface area of the monolayer,  $P_2$  is the measured peak area of the test drug in the acceptor chamber after 2 h of incubation, and  $t$  is the incubation time. The efflux ratio basolateral (B) to apical (A) was calculated by dividing the Papp B-A by the Papp A-B. In addition the compound recovery was calculated. The following reference compounds were used for the classification of the permeability class: Antipyrine, Pyrazosin, Verapamil, Fluvastatin, Cimetidine, Ranitidine, Atenolol, Sulfasalazine.

6. Carbonic Anhydrase Assay

The principle of the assay is based on the hydrolysis of 4-nitrophenyl acetate by carbonic anhydrases (Pocker & Stone, Biochemistry, 1967, 6, 668), with subsequent photometric determination of the dye product 4-nitrophenolate at 400 nm by means of a 96-channel spectral photometer.

2  $\mu$ L of the test compounds, dissolved in DMSO (100-fold final concentration), in a concentration range of 0.03-10  $\mu$ mol/L (final), was pipetted as quadruplicates into the wells of a 96-hole microtiter plate. Wells that contained the solvent without test compounds were used as reference values (1. Wells without carbonic anhydrase for correction of the non-enzymatic hydrolysis of the substrate, and 2. Wells with carbonic anhydrase for determining the activity of the non-inhibited enzyme).

188  $\mu$ L of assay buffer (10 mmol/L of Tris/HCl, pH 7.4, 80 mmol/L of NaCl), with or without 3 units/well of carbonic anhydrase-1 [=human carbonic anhydrase-1 (Sigma, #C4396)] in order to determine carbonic anhydrase-1 inhibition or 3 units/well of carbonic anhydrase-2 [=human carbonic anhydrase-2 (Sigma, #C6165)] for measuring carbonic anhydrase-2 inhibition, was pipetted into the wells of the microtiter plate. The enzymatic reaction was started by the addition of 10  $\mu$ L of the substrate solution (1 mmol/L of 4-nitrophenyl acetate (Fluka #4602), dissolved in anhydrous acetonitrile (final substrate concentration: 50  $\mu$ mol/L). The plate was incubated at room temperature for 15 minutes. Absorption was measured by photometry at a wavelength of 400 nm. The enzyme inhibition was calculated after the measured values were normalized to the absorption of the reactions in the wells without enzyme (=100% inhibition) and to the absorption of reactions in the wells with non-inhibited enzyme (=0% inhibition). IC<sub>50</sub> values were determined by means of a 4 parameter fit using the company's own software.

## PREPARATIVE EXAMPLES

### Syntheses of Compounds

The syntheses of the N-(pyridin-2-yl)pyrimidin-4-amine derivatives according to the present invention are preferably carried out according to the general synthetic sequences, shown in Schemes 1-4.

In addition to said routes described below, also other routes may be used to synthesise the target compounds, in accordance with common general knowledge of a person skilled in the art of organic synthesis. The order of transformations exemplified in the following Schemes is therefore not intended to be limiting, and suitable synthesis steps from various schemes can be combined to form additional synthesis sequences. In addition, interconversion of any of the substituents R<sup>1</sup>, R<sup>2</sup>, R<sup>3</sup>, R<sup>4</sup> and/or R<sup>5</sup> can be achieved before and/or after the exemplified transformations. These modifications can be such as the introduction of protective groups, cleavage of protective groups, reduction or oxidation of functional groups, halogenation, metallation, metal catalysed coupling reactions, substitution or other reactions known to a person skilled in the art. These transformations include those which introduce a functionality allowing for further interconversion of substituents. Appropriate protective groups and their introduction and cleavage are well-known to a person skilled in the art (see for example T. W. Greene and P. G. M. Wuts in Protective Groups in Organic Synthesis, 3<sup>rd</sup> edition, Wiley 1999). Specific examples are described in the subsequent paragraphs. Further, it is possible that two or more successive steps may be performed

65

without work-up being performed between said steps, e.g. a "one-pot" reaction, as it is well-known to a person skilled in the art.

The geometry of the sulfoximine moiety renders the compounds of the general formula (I) chiral. Separation of racemic sulfoximines into their enantiomers can be achieved by methods known to the person skilled in the art, preferably by means of preparative HPLC on chiral stationary phase.

Scheme 1 illustrates a preferred synthetic approach to the compounds of the general formula (I). In the first step, 4,6-dichloropyrimidine (CAS No.: 1193-21-1; 1) is reacted with a boronic acid derivative  $R^2-B(OR)_2$  of formula (2), wherein  $R^2$  is as defined for the compound of general formula (I), to give a compound of formula (3). The boronic acid derivative (2) may be a boronic acid ( $R=H$ ) or an ester of the boronic acid, e.g. its isopropyl ester ( $R=CH(CH_3)_2$ ), preferably an ester derived from pinacol in which the boronic acid intermediate forms a 2-aryl-4,4,5,5-tetramethyl-1,3,2-dioxaborolane ( $R-R=C(CH_3)_2-C(CH_3)_2-$ ).

66

-continued

The coupling reaction is catalyzed by palladium catalysts, e.g. by Pd(0) catalysts like tetrakis(triphenylphosphine) palladium(0) [ $Pd(PPh_3)_4$ ], tris(dibenzylideneacetone)di-palladium(0) [ $Pd_2(dba)_3$ ], or by Pd(II) catalysts like dichlorobis(triphenylphosphine)-palladium(II) [ $Pd(PPh_3)_2Cl_2$ ], palladium(II) acetate and triphenylphosphine or by [1,1'-bis(diphenylphosphino)ferrocene]palladium dichloride.

The reaction is preferably carried out in a mixture of a solvent like 1,2-dimethoxyethane, dioxane, DMF, DME, THF, or isopropanol with water and in the presence of a base like potassium carbonate, sodium bicarbonate or potassium phosphate.

(review: D. G. Hall, Boronic Acids, 2005 WILEY-VCH Verlag GmbH & Co. KGaA, Weinheim, ISBN 3-527-30991-8 and references cited therein).

The reaction is performed at temperatures ranging from room temperature (i.e. approx. 20° C.) to the boiling point of

the respective solvent. Further on, the reaction can be performed at temperatures above the boiling point using pressure tubes and a microwave oven. The reaction is preferably completed after 1 to 36 hours of reaction time.

In the second step, a compound of formula (3), in which  $R^2$  is as defined for the compound of general formula (I), is reacted with a suitable pyridine-2-amine of formula (4), in which  $R^1$ ,  $R^3$  and  $R^4$  are as defined for the compound of general formula (I), to give a compound of formula (5). This coupling reaction can be carried out by a Palladium-catalyzed C—N cross-coupling reactions (for a review on C—N cross coupling reactions see for example: a) L. Jiang, S. L. Buchwald in 'Metal-Catalyzed Cross-Coupling Reactions', 2<sup>nd</sup> ed.: A. de Meijere, F. Diederich, Eds.: Wiley-VCH: Weinheim, Germany, 2004).

Preferred is the herein described use of tris(dibenzylideneacetone)dipalladium(0), (9,9-dimethyl-9H-xanthene-4,5-diyl)bis(diphenylphosphane) and cesium carbonate in dioxane. The reactions are preferably run under an atmosphere of argon for 3-48 hours at 100° C. in a microwave oven or in an oil bath.

Pyridine-2-amines of formula (4) are commercially available in certain cases, or can be prepared by methods known to the person skilled in the art, e.g. from the corresponding 4-hydroxymethylpyridine-2-amine via conversion of the hydroxy group contained therein into a suitable leaving group, such as chloro or bromo, followed by nucleophilic displacement with a thiol of the general formula (10). If needed, the amino group present in said 4-hydroxymethylpyridine-2-amine can be protected by a suitable protecting group. Protecting groups for amino groups present in analogues and methods for their introduction and removal are well known to the person skilled in the art, see e.g. T. W. Greene and P. G. M. Wuts in: Protective Groups in Organic Synthesis, 3<sup>rd</sup> edition, Wiley (1999).

In the third step, imination of a compound of formula (5) gives the corresponding sulfilimine of formula (6) (see for examples: a) C. Bolm et al, Organic Letters, 2004, 6, 1305; b) J. Krüger et al, WO 2012/038411). Said imination is performed by reacting a compound of the formula (5) with trifluoroacetamide and a suitable oxidant, such as 1,3-dibromo-5,5-dimethylhydantoin in the presence of an alkali salt of tert-butanol, such as sodium tert.-butoxide, in a cyclic ether, such as tetrahydrofuran and dioxane, or mixtures thereof, as a solvent.

Oxidation of the sulfilimine of formula (6) followed by deprotection of the trifluoroacetyl group gives the N-unprotected sulfoximine of formula (I) (see for examples: a) A. Plant et al, WO 2006/037945; b) J. Krüger et al, WO 2012/038411). Said oxidation is performed by reacting compounds of the formula (6) with an alkali salt of permanganic acid, such as potassium permanganate, in an aliphatic ketone of the formula  $C_1-C_2-C(O)-C_1-C_2$ -alkyl, such as acetone, as a solvent. Unless the trifluoroacetyl group present in the compounds of formula (6) has been cleaved off during the abovementioned oxidation process, it can be removed by treatment of the resulting intermediate with a suitable base, such as a carbonate of an alkali or earth alkali metal, preferably potassium carbonate, in a suitable alcohol, such as an aliphatic alcohol  $C_1-C_6$ -alkyl-OH, preferably methanol.

Said oxidation is also preferably performed by reacting compounds of formula (6) with a peroxomonosulfate based oxidant, such as Oxone® (CAS No. 37222-66-5), in a suitable solvent mixture, such as methanol/water and as the circumstances require additional DMF, while controlling the

pH of the reaction mixture with aqueous potassium hydroxide solution to give N-unprotected sulfoximine of formula (I) ( $R^5=H$ ).

Pyridine-2-amines of formula (4) are commercially available in certain cases, or can be prepared by methods known to the person skilled in the art, e.g. from the corresponding 4-hydroxymethylpyridine-2-amine via conversion of the hydroxy group contained therein into a suitable leaving group, such as chloro or bromo, followed by nucleophilic displacement with a thiol of the general formula  $R^1-SH$ , in which  $R^1$  is defined as defined for the compound of general formula (I). If needed, the amino group present in said 4-hydroxymethylpyridine-2-amine can be protected by a suitable protecting group. Protecting groups for amino groups present in analogues and methods for their introduction and removal are well known to the person skilled in the art, see e.g. T. W. Greene and P. G. M. Wuts in: Protective Groups in Organic Synthesis, 3<sup>rd</sup> edition, Wiley (1999).

Thiols of formula  $R^1-SH$  are known to the person skilled in the art and are commercially available in considerable variety.

N-unprotected sulfoximines of formula (I) may be reacted to give N-functionalized derivatives of formula (I). There are multiple methods for the preparation of N-functionalized sulfoximines by functionalization of the nitrogen of the sulfoximine group:

An alternative synthesis approach to the N-(pyridin-2-yl)pyrimidin-4-amine derivatives according to the present invention is described in Scheme 2.

69

In the first step, a compound of formula (3), in which  $R^2$  is as defined for the compound of general formula (I), is reacted with a suitable pyridine-2-amine of formula (7), in which  $R^3$  and  $R^4$  are as defined for the compound of general formula (I), to give a compound of formula (8). This coupling reaction can be carried out by a Palladium-catalyzed C—N cross-coupling reactions (for a review on C—N

cross coupling reactions see for example: a) L. Jiang, S. L. Buchwald in 'Metal-Catalyzed Cross-Coupling Reactions', 2<sup>nd</sup> ed.: A. de Meijere, F. Preferred is the herein described use of tris(dibenzylideneacetone)dipalladium(0), (9,9-dimethyl-9H-xanthene-4,5-diyl)bis(diphenylphosphane) and cesium carbonate in dioxane. The reactions are preferably run under an atmosphere of argon for 3-48 hours at 100° C. in a microwave oven or in an oil bath. Pyridine-2-amines of formula (7) are commercially available in certain cases, or can be prepared by methods known to the person skilled in the art, e.g. by reduction of the corresponding carboxylic acids or esters thereof.

In the second step, a compound of formula (8), in which  $R^2$ ,  $R^3$  and  $R^4$  are as defined for the compound of general formula (I), is converted to a compound of formula (9), in which  $R^2$ ,  $R^3$  and  $R^4$  are as defined for the compound of general formula (I) and in which LG represents a leaving group, preferably chloro or bromo. Preferred is the herein described use of thionyl chloride in NMP or DMF and DCM for the formation the respective chloromethyl pyridines (LG=Cl). A possibility for the formation of the respective bromomethyl pyridines (LG=Br) is the use of tetrabromomethane and triphenylphosphane in DCM (see for example: Polla et al, Bioorganic and Medicinal Chemistry, 2004, 12, 1151).

In the third step, a compound of formula (9) is converted to a thioether of formula (5), in which  $R^1$ ,  $R^2$ ,  $R^3$  and  $R^4$  are as defined for the compound of general formula (I), by reaction with suitable thiols of formula (10), in which  $R^1$  is as defined for the compound of formula (I), under basic conditions, yielding the corresponding thioethers of formula (5) (see for example: Sammond et al, Bioorg. Med. Chem. Lett. 2005, 15, 3519). Thiols of formula (10) are known to the person skilled in the art and are commercially available in considerable variety.

In the final steps, the thioether of formula (5) is converted to the corresponding sulfoximine of formula (I) as described in Scheme 1.

Another alternative synthesis approach to the N-(pyridin-2-yl)pyrimidin-4-amine derivatives according to the present invention is described in Scheme 3.

In the first step, 6-chloropyrimidin-4-amine (CAS No.: 5305-59-9; 11) is reacted with a boronic acid derivative  $R^2-B(OR)_2$  of formula (2), wherein  $R^2$  is as defined for the compound of general formula (I), to give a compound of formula (12). The boronic acid derivative (2) may be a boronic acid ( $R-H$ ) or an ester of the boronic acid, e.g. its isopropyl ester ( $R-CH(CH_3)_2$ ), preferably an ester derived from pinacol in which the boronic acid intermediate forms a 2-aryl-4,4,5,5-tetramethyl-1,3,2-dioxaborolane ( $R-R-C(CH_3)_2-C(CH_3)_2-$ ).

The coupling reaction is catalyzed by palladium catalysts, e.g. by Pd(O) catalysts like tetrakis(triphenylphosphine) palladium(0)  $[Pd(PPh_3)_4]$ , tris(dibenzylideneacetone)di-palladium(0)  $[Pd_2(dba)_3]$ , or by Pd(II) catalysts like dichlorobis(triphenylphosphine)-palladium(II)  $[Pd(PPh_3)_2Cl_2]$ , palladium(II) acetate and triphenylphosphine or by [1,1'-bis(diphenylphosphino)ferrocene]palladium dichloride.

The reaction is preferably carried out in a mixture of a solvent like 1,2-dimethoxyethane, dioxane, DMF, DME, THF, or isopropanol with water and in the presence of a base like potassium carbonate, sodium bicarbonate or potassium phosphate.

(review: D. G. Hall, Boronic Acids, 2005 WILEY-VCH Verlag GmbH & Co. KGaA, Weinheim, ISBN 3-527-30991-8 and references cited therein).

The reaction is performed at temperatures ranging from room temperature (i.e. approx. 20° C.) to the boiling point of the respective solvent. Further on, the reaction can be performed at temperatures above the boiling point using pressure tubes and a microwave oven. The reaction is preferably completed after 1 to 36 hours of reaction time.

In the second step, a compound of formula (12), in which  $R^2$  is as defined for the compound of general formula (I), is reacted with a suitable pyridine of formula (13), in which  $R^1$ ,  $R^3$  and  $R^4$  are as defined for the compound of general formula (I), and wherein LG represents a leaving group, such as chloro or bromo, to give a compound of formula (8). This coupling reaction can be carried out by a Palladium-catalyzed C—N cross-coupling reactions (for a review on C—N cross coupling reactions see for example: a) L. Jiang, S. L. Buchwald in 'Metal-Catalyzed Cross-Coupling Reactions', 2<sup>nd</sup> ed.: A. de Meijere, F. Diederich, Eds.: Wiley-VCH: Weinheim, Germany, 2004).

Preferred is the herein described use of tris(dibenzylideneacetone)dipalladium(0), (9,9-dimethyl-9H-xanthene-4,5-diyl)bis(diphenylphosphane) and cesium carbonate in dioxane. The reactions are preferably run under an atmosphere of argon for 3-48 hours at 100° C. in a microwave oven or in an oil bath.

In the subsequent steps, the benzylic alcohol of formula (8) is first converted to the corresponding thioether of formula (5) as described in Scheme 2, and then transformed into the corresponding sulfoximine of formula (I) as described in Scheme 1.

Pyridine derivatives of the formula (13) are known to the person skilled in the art, and are commercially available in considerable variety.

72

Another alternative synthesis approach to the N-(pyridin-2-yl)pyrimidin-4-amine derivatives of formula (I) according to the present invention is described in Scheme 4.

A compound of formula (12) is reacted with a suitable pyridine derivative of formula (14), in which  $R^1$ ,  $R^3$  and  $R^4$  are as defined for the compound of general formula (I), and in which LG represents a leaving group, preferably chloro, to give a compound of formula (5). This coupling reaction can be carried out by a Palladium-catalyzed C—N cross-coupling reaction (for a review on C—N cross coupling reactions see for example: a) L. Jiang, S. L. Buchwald in 'Metal-Catalyzed Cross-Coupling Reactions', 2<sup>nd</sup> ed.: A. de Meijere, F. Diederich, Eds.: Wiley-VCH: Weinheim, Germany, 2004).

Preferred is the herein described use of chloro(2-dicyclohexylphosphino-2',4',6'-tri-iso-propyl-1,1'-biphenyl)[2-(2-aminoethyl)phenyl]palladium(II) methyl-tert-butylether adduct, 2-(dicyclohexylphosphino)-2',4',6'-triisopropylbiphenyl and potassium phosphate in toluene and NMP. The reactions are preferably run under an atmosphere of argon for 2-24 hours at 100-130° C. in a microwave oven or in an oil bath.

In the final steps, the thioether of formula (5) is converted to the corresponding sulfoximine of formula (I) as described in scheme 1.

Pyridine derivatives of the formula (14) can be prepared according to methods known to the person skilled in the art, e.g. by conversion of a halomethyl group into the thioether present in compound of the formula (14) using a thiol of the formula (10), in which  $R^1$  is as defined for the compound of general formula (I), in a similar fashion as described supra for pyridine amines of the formula (4) and for the conversion of intermediates of formula (9) into thioethers of formula (5) in Scheme 2. Said halomethyl pyridine precursors are known to the person skilled in the art, and are commercially available in certain cases.
