## 1

## LIGHT-EMITTING ELEMENT

## REFERENCE TO RELATED APPLICATION

This application is a continuation application of U.S. patent application Ser. No. 14/866,232, filed Sep. 25, 2015, which is a continuation in-part application of U.S. patent application Ser. No. 14/302,036, now U.S. Pat. No. 9,153,747, filed Jun. 11, 2014, which claims the right of priority based on TW application Serial No. 102124862, filed on Jul. 10, 2013, the contents of which are hereby incorporated by reference in their entireties.

## TECHNICAL FIELD

The disclosure is related to a light-emitting element and more particularly, a light-emitting element with high reflectivity.

## DESCRIPTION OF THE RELATED ART

Optical element such as LEDs are widely adopted in optical display devices, traffic lights, information storage apparatuses, communication apparatuses, lighting apparatuses, and medical appliances. The abovementioned LEDs can further connect to other devices for forming a light-emitting device. FIG. 1 illustrates a schematic structure of a light-emitting device. As shown in FIG. 1, a light-emitting device 1 includes a sub-carrier 12 having a circuit 14, a soldering material 16 on the sub-carrier 12 for mounting the LED 11 on the sub-carrier 12 and electrically connecting the LED 11 with the circuit 14 of the sub-carrier 12, and an electrical connecting structure 18 for electrically connecting with an electrode 15 of the LED 11 and the circuit 14 of the sub-carrier 12. The abovementioned sub-carrier 12 can be a lead frame or mounting substrate with a large size.

## SUMMARY OF THE DISCLOSURE

A light-emitting element comprises a light-emitting stack comprising an active layer for emitting a light; a window layer on the light-emitting stack; and a first insulative layer having a first refractive index on the window layer; wherein the first insulative layer has a first refractive index, and the window layer has a second refractive index, and a difference between the first refractive index and the second refractive index is larger than 1.5.

## BRIEF DESCRIPTION OF THE DRAWING

The accompanying drawing is included to provide easy understanding of the application, and is incorporated herein and constitutes a part of this specification. The drawing illustrates the embodiment of the application and, together with the description, serves to illustrate the principles of the application.

FIG. 1 illustrates a schematic structure of a conventional light-emitting device.

FIG. 2A illustrates a top view of a light-emitting element in accordance with an embodiment of the application.

FIG. 2B illustrates a cross section of FIG. 2A along a profile line AA' in accordance with one embodiment.

FIG. 3 illustrates the percentage of the surface area of the first contact upper surface to a sum of surface areas of the first contact upper surface and the second contact upper surface versus power.

## 2

FIG. 4A illustrates a top view of a light-emitting element in accordance with an embodiment of the application.

FIG. 4B illustrates a cross section of FIG. 4A along a profile line AA' in accordance with one embodiment.

FIG. 5 illustrates an exploded view of a lamp in accordance with an embodiment of the application.

## DETAILED DESCRIPTION OF THE EMBODIMENTS

To better and concisely explain the application, the same name or the same reference number given or appeared in different paragraphs or figures along the specification should have the same or equivalent meanings while it is once defined anywhere of the application.

The following shows the description of embodiments of the application in accordance with the drawing.

## First Embodiment

FIG. 2A illustrates a top view of a light-emitting element in accordance with an embodiment of the application. FIG. 2B illustrates a cross section of FIG. 2A along a profile line AA'. As shown in FIG. 2B, a light-emitting element 2 includes a substrate 20, a conducting adhesive layer 21 on the substrate 20, a reflection structure 22 on the conducting adhesive layer 21, a transparent conducting structure 23 on the reflection structure 22, a window layer 29 on the transparent conducting structure 23, a non-oxide insulative layer 24 between the transparent conducting structure 23 and the window layer 29, a light-emitting stack 25 on the window layer 29, an electrical contact layer 26 on the light-emitting stack 25, a first electrode 27 on the light-emitting stack 25 and the electrical contact layer 26, and a second electrode 28 below the substrate 20, wherein the light-emitting stack 25 includes a first semiconductor layer 251 between the window layer 29 and the first electrode 27, an active 252 between the first semiconductor layer 251 and the first electrode 27, and a second semiconductor layer 253 between the active layer 252 and the first electrode 27.

The first electrode 27 and/or the second electrode 28 are for an external voltage and made of a transparent conducting material or a metal material. The transparent conducting material includes, but is not limited to indium tin oxide (ITO), indium oxide (InO), tin oxide (SnO), cadmium tin oxide (CTO), antimony tin oxide (ATO), aluminum zinc oxide (AZO), zinc tin oxide (ZTO), gallium zinc oxide (GZO), indium tungsten oxide (IWO), zinc oxide (ZnO), aluminum gallium arsenide (AlGaAs), gallium nitride (GaN), gallium phosphide (GaP), gallium arsenide (GaAs), gallium arsenide phosphide (GaAsP), indium zinc oxide (IZO), or diamond like carbon (DLC). The metal material includes, but is not limited to aluminum (Al), chromium (Cr), copper (Cu), tin (Sn), gold (Au), nickel (Ni), titanium (Ti), platinum (Pt), lead (Pb), zinc (Zn), cadmium (Cd), antimony (Sb), cobalt (Co), or an alloy including the abovementioned. The first electrode 27 includes a current input portion 271 and an extension portion 272. As shown in FIG. 2A, the current input portion 271 is substantially on a center of the second semiconductor layer 253, the extension portion 272 includes a first branch 2721 extends from the current input portion 271 to a boundary of the light-emitting element 2, and a second branch 2722 extends from the first branch 2721 for improving current diffusion. As shown in FIG. 2B, the extension portion 272 includes a protrusive portion 273 on the electrical contact layer 26, covering at least one surface of the electrical contact layer 26 for

increasing ohmic contact area with the electrical contact layer **26** and lowering resistance of the light-emitting element **2**, wherein the protrusive portion **273** higher than the current input portion **271**.

The electrical contact layer **26** is between the second branch **2722** and the light-emitting stack **25** for forming an ohmic contact between the second branch **2722** and the light-emitting stack **25**. A resistance between the electrical contact layer **26** and the second branch **2722** and a resistance between the electrical contact layer **26** and the light-emitting stack **25** are less than a resistance between the first electrode **27** and the light-emitting stack **25**. A material of the electrical contact layer **26** can be a semiconductor material including at least one element, like gallium (Ga), aluminum (Al), indium (In), phosphorus (P), nitrogen (N), zinc (Zn), cadmium (Cd), or selenium (Se). A polarity of the electrical contact layer **26** can be the same as the polarity of the second semiconductor layer **253**.

A material of the light-emitting stack **25** can be a semiconductor material, including more than one element like gallium (Ga), aluminum (Al), indium (In), phosphorus (P), nitrogen (N), zinc (Zn), cadmium (Cd), or selenium (Se). The polarities of the first semiconductor **251** and the second semiconductor layer **253** are different for generating electrons or holes. A light-exiting upper surface **254** of the second semiconductor layer **253** can be a rough surface for reducing total internal reflection, so as to increase luminous efficiency of the light-emitting element **2**. The active layer **252** can emit one or more kinds of color lights which are visible or invisible and can be a single-heterostructure, a double-heterostructure, a double side double-heterostructure, multi-quantum wells structure, or quantum dots. The polarity of the window layer **29** can be the same as the polarity of the first semiconductor layer **251** for serving as a light extraction layer to increase luminous efficiency of the light-emitting element **2**. The window layer **29** with respect to light emitted from the active layer **252** is transparent. Additionally, a material of the window layer **29** can be a transparent conducting material including but is not limited to indium tin oxide (ITO), indium oxide (InO), tin oxide (SnO), cadmium tin oxide (CTO), antimony tin oxide (ATO), aluminum zinc oxide (AZO), zinc tin oxide (ZTO), gallium zinc oxide (GZO), indium tungsten oxide (IWO), zinc oxide (ZnO), magnesium oxide (MgO), aluminum gallium arsenide (AlGaAs), gallium nitride (GaN), gallium phosphide (GaP), or indium zinc oxide (IZO).

The transparent conducting structure **23** with respect to light emitted from the light-emitting stack **25** is transparent and can improve the ohmic contact between the window layer **251** and the reflection structure **22**, the current conduction, and the current diffusion. Additionally, the transparent conducting structure **23** and the reflection structure **22** can form an omni-directional reflector (ODR) which is made of a transparent material including but is not limited to indium tin oxide (ITO), indium oxide (InO), tin oxide (SnO), cadmium tin oxide (CTO), antimony tin oxide (ATO), aluminum zinc oxide (AZO), zinc tin oxide (ZTO), gallium zinc oxide (GZO), indium tungsten oxide (IWO), zinc oxide (ZnO), gallium phosphide (GaP), indium cerium oxide (ICO), indium tungsten oxide (IWO), indium titanium oxide (ITiO), indium zinc oxide (IZO), indium gallium oxide (IGO), gallium aluminum zinc oxide (GAZO), or a combination thereof. The transparent conducting structure **23** includes a first conducting oxide layer **230** below the non-oxide insulative layer **24** and a second conducting oxide layer **232** between the light-emitting stack **25** and the first conducting oxide layer **230**. The materials of the first

conducting oxide layer **230** and the second conducting oxide layer **232** are different. In another embodiment, the first conducting oxide layer **230** has at least one different element in comparison with the composition of the material of the second conducting oxide layer **232**. For example, the material of the first conducting oxide layer **230** is indium zinc oxide (IZO) and the material of the second conducting oxide layer **232** is indium tin oxide (ITO). The second conducting oxide layer **232** can directly contact with the non-oxide insulative layer **24** and/or the window layer **29** and cover at least one surface of the non-oxide insulative layer **24**.

The transmittance of the non-oxide insulative layer **24** to the light emitted from the light-emitting stack **25** is greater than 90% and the refractive index of the non-oxide insulative layer **24** is less than 1.4, which is better between 1.3~1.4. A material of the non-oxide insulative layer **24** can be a non-oxide insulative material, for example, benzocyclobutene (BCB), cyclic olefin copolymers (COC), fluorocarbon polymer, silicon nitride (SiNx). In another embodiment, a material of the non-oxide insulative layer **24** can include a halide, a compound of group IIA, or a compound of group VIIA, for example, calcium difluoride (CaF<sub>2</sub>), carbon tetrafluoride (CF<sub>4</sub>) or magnesium difluoride (MgF<sub>2</sub>), and a refractive index of the non-oxide insulative layer **24** is less than refractive indexes of the window layer **29** and the transparent conducting structure **23**. Since the refractive index of the non-oxide insulative layer **24** is less than the refractive indexes of the window layer **29** and the transparent conducting structure **23**, and a critical angle of an interface between the window layer **29** and the non-oxide insulative layer **24** is less than a critical angle of an interface between the window layer **29** and the transparent conducting structure **23**, the probability of total internal reflection that occurs when the light emitted from the light-emitting stack **25** passes through an interface between the light-emitting stack **25** and the non-oxide insulative layer **24** is increased accordingly. Additionally, the light that does not encounter total internal reflection at the interface between the window layer **29** and the transparent conducting structure **23** encounters totally internal reflection at the interface between the transparent conducting structure **23** and the non-oxide insulative layer **24** so the light extraction efficiency of the light-emitting element **2** is increased. The transparent conducting structure **23** has a first contact upper surface **231** contacting the window layer **29**, and the non-oxide insulative layer **24** has a second contact upper surface **241** contacting the window layer **29**. The first contact upper surface **231** and the second contact upper surface **241** are at the same level substantially, namely, a distance between the first contact upper surface **231** and the light-exiting upper surface **254** is substantially equal to a distance between the second contact upper surface **241** and the light-exiting upper surface **254**. FIG. 3 illustrates the percentage of the surface area of the first contact upper surface to a sum of surface areas of the first contact upper surface and the second contact upper surface (hereafter, surface percentage) versus power of the light-emitting element **2**. As shown in FIG. 3, when the surface area of the first contact upper surface **231** is about 10%~50% of a sum of the surface areas of the first contact upper surface **231** and the second contact upper surface **241**, the power of the light-emitting element **2** is greater than 50 mW, which is better than that of a light-emitting element with a surface percentage greater than 50%. In a preferred embodiment, the surface percentage of the light-emitting element **2** is 12.5~25%, and in such case, power of the light-emitting element **2** can be greater than 55 mW. In other words, when a ratio of a surface area of the non-oxide

insulative layer **24** to a surface area of the window layer **29** is about 0.5~0.9, the light-emitting element **2** has better power performance. In another embodiment, the second contact upper surface **241** can be a rough surface to scatter the light from the light-emitting stack **25** for increasing luminous efficiency of the light-emitting element **2**. The non-oxide insulative layer **24** can be disposed as a pattern, for example, a pattern right under the electrical contact layer **26** and/or the current input portion **271** for diffusing a current. In another embodiment, the non-oxide insulative layer **24** can have random pattern or is not located right under the electrical contact layer **26** and/or the current input portion **271**. A thickness of the non-oxide insulative layer **24** is less than a half of a thickness of the transparent conducting structure **23**. In yet another embodiment, a thickness of the non-oxide insulative layer **24** is less than  $\frac{1}{5}$  of a thickness of the transparent conducting structure **23** to prevent a planarization process for the transparent conducting structure **23** from damaging the non-oxide insulative layer **24**. At least one surface of the non-oxide insulative layer **24** is covered by the transparent conducting structure **23** for strongly joining the transparent conducting structure **23** to the window layer **29** so as to enhance mechanical strength. In another embodiment, the non-oxide insulative layer **24** can directly join the reflection structure **22** for preventing the transparent conducting structure **23** and the reflection structure **22** from peeling because of insufficient adhesion force. Additionally, the non-oxide insulative layer **24** further includes a plurality of pores **242** penetrating the non-oxide insulative layer **24** and the transparent conducting structure **23** fills the plurality of pores **242** for forming an ohmic contact.

The reflection structure **22** can reflect light emitted from the light-emitting stack **25**, and the material of the reflection structure **22** can be metal material including, but not limited to copper (Cu), aluminum (Al), tin (Sn), gold (Au), silver (Ag), lead (Pb), titanium (Ti), nickel (Ni), platinum (Pt), tungsten (W) or an alloy made of the above mentioned. The reflection structure **22** includes a reflection layer **226**, a reflective adhesion layer **224** below the reflection layer **226**, a barrier layer **222** below the reflective adhesion layer **224**, and an ohmic contact layer **220** below the barrier layer **222**. The reflection layer **226** can reflect light emitted from the light-emitting stack **25**, the reflective adhesion layer **224** adheres to the reflection layer **226** and the barrier **222**, and the barrier layer **222** can prevent the material of the reflection layer **226** from diffusing to the ohmic contact layer **220** and damaging the reflection layer **226** so as to reduce the reflection efficiency of the reflection layer **226**. The ohmic contact layer **220** has ohmic contacts with the conducting adhesive layer **21**. The conducting adhesive layer **21** connects to the substrate **20** and the reflection structure **22** and includes a plurality of sub-layers (not shown in figures) and can be a transparent conducting material or a metal material. The transparent conducting material includes, but is not limited to indium tin oxide (ITO), indium oxide (InO), tin oxide (SnO), cadmium tin oxide (CTO), antimony tin oxide (ATO), aluminum zinc oxide (AZO), zinc tin oxide (ZTO), gallium zinc oxide (GZO), zinc oxide (ZnO), gallium phosphide (GaP), indium cerium oxide (ICO), indium tungsten oxide (IWO), indium titanium oxide (ITiO), indium zinc oxide (IZO), indium gallium oxide (IGO), gallium aluminum zinc oxide (GAZO), or a combination thereof. The metal material includes, but is not limited to copper (Cu), aluminum (Al), tin (Sn), gold (Au), silver (Ag), lead (Pb), titanium (Ti), nickel (Ni), platinum (Pt), tungsten (W), or an alloy made of the above mentioned.

The substrate **20** can support the light-emitting stack **25** and other layers or structures and be made of a transparent material or a conducting material. For example, the transparent material can include, but not limited to sapphire, diamond, glass, epoxy, quartz, acryl,  $\text{Al}_2\text{O}_3$ , zinc oxide (ZnO), or aluminum nitride (AlN); the conducting material can include, but be not limited to copper (Cu), aluminum (Al), molybdenum (Mo), tin (Sn), zinc (Zn), cadmium (Cd), nickel (Ni), cobalt (Co), diamond like carbon (DLC), graphite, carbon fiber, metal matrix composite (MMC), ceramic matrix composite (CMC), silicon (Si), zinc selenide (ZnSe), gallium arsenide (GaAs), silicon carbide (SiC), gallium phosphide (GaP), gallium arsenide phosphide (GaAsP), indium phosphide (InP),  $\text{LiGaO}_2$ , or  $\text{LiAlO}_2$ .

FIG. **5** illustrates an exploded view of a lamp. A lamp **4** includes a lamp cover **41**, a lens **42** in the lamp cover **41**, a light-emitting module **44** under the lens **42**, a base **45** having a heat sink **46** for carrying the light-emitting module **44**, a connection portion **47**, and an electrical connector **48**, wherein the connection portion **47** connects to the base **45** and the electrical connector **48**, and the light-emitting module **44** has a carrier **43** and a plurality of the light-emitting elements **40** of any of the abovementioned embodiments on the carrier **43**.

#### Second Embodiment

FIG. **4B** shows a cross section along a profile line AA' of FIG. **4A**. As shown in FIG. **4B**, a light-emitting element **100** includes a substrate **20**, a conducting adhesive layer **21** on the substrate **20**, a reflection structure **22** on the conducting adhesive layer **21**, a transparent conducting structure **23** on the reflection structure **22**, a window layer **29** on the transparent conducting structure **23**, an insulative structure **3** between the transparent conducting structure **23** and the window layer **29**, a light-emitting stack **25** on the window layer **29**, an electrical contact layer **26** on the light-emitting stack **25**, wherein the electrical contact layer **26** is patterned to cover a part of the light-emitting stack **25** and exposes another part of the light-emitting stack **25**. A first electrode **27** on the light-emitting stack **25** and the electrical contact layer **26**, and a second electrode **28** below the substrate **20**. The light-emitting stack **25** includes a first semiconductor layer **251**, an active **252**, and a second semiconductor layer **253** sequentially on the window layer **29**, wherein a part of the second semiconductor layer **253** contacts the electrical contact layer **26** and another part of the second semiconductor layer **253** is exposed from the electrical contact layer **26**. In one embodiment, the first electrode **27** and/or the second electrode **28** are used for die-bonding to an external device, such as a package sub-mount or a printed circuit board through a wire or a solder bump. The material of the first electrode **27** and/or the second electrode **28** comprises transparent conducting material, such as indium tin oxide (ITO), indium zinc oxide (IZO), indium oxide (InO), tin oxide (SnO), cadmium tin oxide (CTO), antimony tin oxide (ATO), aluminum zinc oxide (AZO), zinc tin oxide (ZTO), gallium zinc oxide (GZO), indium tungsten oxide (IWO), zinc oxide (ZnO), aluminum gallium arsenide (AlGaAs), gallium nitride (GaN), gallium phosphide (GaP), gallium arsenide (GaAs), gallium arsenide phosphide (GaAsP), diamond like carbon (DLC) and the combination thereof, or metal, such as aluminum (Al), chromium (Cr), copper (Cu), tin (Sn), gold (Au), nickel (Ni), titanium (Ti), platinum (Pt), lead (Pb), zinc (Zn), cadmium (Cd), antimony (Sb), cobalt (Co), and the combination thereof.

The first electrode **27** includes a current input portion **271** and an extension portion **272**. As shown in FIG. 4A, the current input portion **271** is substantially on a center of the second semiconductor layer **253**. The extension portion **272** includes multiple first branches **2721** radially extending from the current input portion **271** toward a boundary of the light-emitting element **100**, and multiple second branches **2722** respectively extending from the first branches **2721** and parallel to the boundary of the light-emitting element **100** for improving current spreading over the second semiconductor layer **253**. As shown in FIG. 4B, the electrical contact layer **26** is arranged as a plurality of stripes each of which is enclosed and fully covered by each of the second branches **2722**. The electrical contact layer **26** is formed of semiconductor material, such as GaAs or GaN, and the polarity of the electrical contact layer **26** is the same as the polarity of the second semiconductor layer **253**. The first electrode **27** comprises metal, such as Au, Ge, Ni, Ti, Pt, Al, Pd or the alloy thereof. Thus, the electrical contact layer **26** forms an ohmic contact with the extension portion **272** of the first electrode **27** for decreasing the electrical resistance between the extension portion **272** and the second semiconductor layer **253** and lowering the forward voltage of the light-emitting element **100**. The current input portion **271** and the portion of the extension portion **272** not covering the electrical contact layer **26** directly contact the second semiconductor layer **253** and form a Schottky contact with the second semiconductor layer **253**.

A material of the active layer **252** comprises a III-V compound material, e.g.  $\text{Al}_p\text{Ga}_q\text{In}_{(1-p-q)}\text{P}$  wherein  $0 \leq p, q \leq 1$  for emitting red, orange, yellow or amber light, or  $\text{Al}_x\text{In}_y\text{Ga}_{(1-x-y)}\text{N}$  wherein,  $0 \leq x, y \leq 1$  for emitting blue, UV or green light. The polarities of the first semiconductor **251** and the second semiconductor layer **253** are different for providing carriers, such as electrons or holes. A light-exiting upper surface **254** of the second semiconductor layer **253** not covered by the first electrode **27** is a rough surface for scattering the light from the light-emitting stack **25**, so as to increase luminous efficiency of the light-emitting element **100**. The active layer **252** can emit single or multiple colors of light and comprises a single-heterostructure (SH), a double-heterostructure (DH), a double side double-heterostructure (DDH), multi-quantum wells (MQW) structure, or quantum dots. A polarity or conductivity-type of the window layer **29** can be the same as that of the first semiconductor layer **251** for spreading current. The window layer **29** has a lower sheet resistance than the first semiconductor layer **251** and is transparent to light emitted from the active layer **252**. Additionally, a material of the window layer **29** can be a transparent conducting oxide, such as indium tin oxide (ITO), indium oxide (InO), tin oxide (SnO), cadmium tin oxide (CTO), antimony tin oxide (ATO), aluminum zinc oxide (AZO), zinc tin oxide (ZTO), gallium zinc oxide (GZO), indium tungsten oxide (IWO), zinc oxide (ZnO) and indium zinc oxide (IZO), or semiconductor material, such as aluminum gallium arsenide (AlGaAs), gallium nitride (GaN) and gallium phosphide (GaP).

The insulative structure **3** comprises a first insulative layer **31** and a second insulative layer **32**, wherein the first insulative layer **31** is formed on and contacts the window layer **29**, and the second insulative layer **32** is formed on the first insulative layer **31** and has the same shape as the first insulative layer **31** from the top-view of the light-emitting element **100**. In the embodiment, the transmittances of the first insulative layer **31** and the second insulative layer **32** to the light emitted from the active layer **252** are both greater than 90%. The refractive index of the first insulative layer **31**

is smaller than the refractive index of the window layer **29** and the refractive index of the second insulative layer **32**. In one embodiment, the first insulative layer **31** is made of non-oxide material including a compound of group IIA, a compound of group IVA or a compound of group VIIA. Specifically, the non-oxide material comprises a compound with carbon-fluorine bond, such as  $\text{CF}_4$ ,  $\text{C}_2\text{F}_6$ ,  $\text{C}_3\text{F}_6$ ,  $\text{C}_3\text{F}_8$ ,  $\text{C}_4\text{F}_8$ ,  $\text{C}_5\text{F}_{12}$ ,  $\text{C}_6\text{F}_{14}$ , or other fluorocarbon having a formula of  $\text{C}_x\text{F}_y$ . Specifically, the non-oxide material comprises magnesium fluoride having a formula of  $\text{MgF}_x$ , such as  $\text{MgF}_2$ . The non-oxide material of the first insulative layer **31** has a refractive index between 1.3 and 1.4. The second insulative layer **32** is made of oxide, such as  $\text{SiO}_x$ , or nitride, such as  $\text{SiN}_x$ , and has a refractive index between 1.4 and 1.8. The first insulative layer **31** and the second insulative layer **32** are patterned to form multiple pores **242'** exposing the window layer **29**. When the first insulative layer **31** comprises magnesium difluoride ( $\text{MgF}_2$ ), the first insulative layer **31** and the second insulative layer **32** can be patterned by lift-off process at the same time. When the first insulative layer **31** comprises fluorocarbon compound, the first insulative layer **31** and the second insulative layer **32** can be patterned by wet etching process at the same time wherein the wet-etching solution comprises buffered oxide etching solution (BOE) or hydrofluoric acid (HF). Therefore, the first insulative layer **31** and the second insulative layer **32** are textured to have the same patterns from a top view of the light-emitting element **100**. From a top view of the light-emitting element **100**, the multiple pores **242'** are uniformly distributed on the window layer **29** for improving the electrical current distribution over the window layer **29**. The top-view shape of the multiple pores **242'** can be circle or polygon, such as square. As shown in FIG. 4A, the shape of each of the multiple pores **242'** is a circle with a diameter between 2  $\mu\text{m}$  and 20  $\mu\text{m}$ .

Since the refractive index of the first insulative layer **31** is at least 0.5 less than the refractive indexes of the window layer **29**, the first insulative layer **31** and the window layer **29** form a total-internal-reflection (TIR) interface to reflect the light emitted from the light-emitting stack **25**.

The transparent conducting structure **23** has a first surface **231** contacting the window layer **29**, and the first insulative layer **31** has a second surface **241** contacting the window layer **29**, wherein the first surface **231** and the second surface **241** are substantially at the same level. In one embodiment, the surface area of the first surface **231** is about 10%~50% of a sum of the surface areas of the first surface **231** and the second surface **241**, and, in another embodiment, the surface area of the first surface **231** is about 12.5%~25% of a sum of the surface areas of the first surface **231** and the second surface **241**. In another embodiment, the second surface **241** can be a rough surface for scattering the light from the light-emitting stack **25** for increasing luminous efficiency of the light-emitting element **100**.

In one embodiment, for a light-emitting element with an top-view area larger than 0.25  $\text{mm}^2$ , the multiple pores is preferably not overlapped the electrical contact layer **26**, or the insulative structure **3** is preferably disposed as a pattern right under the electrical contact layer **26** and/or the current input portion **271** for better current spreading.

A thickness of the insulative structure **3** is between 20 nm and 2  $\mu\text{m}$  or preferably between 100 nm and 300 nm, wherein the thickness of the first insulative layer **31** is between 10 nm and 1  $\mu\text{m}$  or preferably between 50 nm and 150 nm, and the thickness of the second insulative layer **32** is also between 10 nm and 1  $\mu\text{m}$  or preferably between 50 nm and 150 nm.

The transparent conducting structure **23** includes a first conducting oxide layer **230** below the insulative structure **3** and a second conducting oxide layer **232** between the light-emitting stack **25** and the first conducting oxide layer **230**. The second conducting oxide layer **232** conformably covers the insulative structure **3** and fills in the multiple pores **242** to directly contact the window layer **29**. The first conducting oxide layer **230** conformably covers the second conducting oxide layer **232**. In the present embodiment, a thickness of the second conducting oxide layer **232** is between 1 nm and 1  $\mu$ m, preferably between 10 nm and 100 nm, or more preferably between 1 nm and 20 nm, and a thickness of the first conducting oxide layer **230** is between 1 nm and 10000 nm, preferably between 10 nm and 1000 nm or more preferably between 50 nm and 150 nm. The first conducting oxide layer **230** comprises a material different from that of the second conducting oxide layer **232**. In another embodiment, the first conducting oxide layer **230** comprises one element different from the material of the second conducting oxide layer **232**. For example, the first conducting oxide layer **230** is made of indium zinc oxide (IZO), which has a refractive index between 2.0 and 2.2, and the second conducting oxide layer **232** is made of indium tin oxide (ITO), which has a refractive between 1.8 and 2.0. In the embodiment, the refractive index of the first conducting oxide layer **230** is larger than the refractive index of the second conducting oxide layer **232**, the refractive index of the second conducting oxide layer **232** is larger than the refractive index of the second insulative layer **32**, and the refractive index of the second insulative layer **32** is larger than the refractive index of the first insulative layer **31** so the refractive indices of the first insulative layer **31**, the second insulative layer **32**, the second conducting oxide layer **232** and the first conducting oxide layer **230** gradually increase along the direction from the light-emitting stack toward the reflection structure **22** for reducing the probability of occurrence of total-internal-reflection (TIR) between the first insulative layer **31** and the second insulative layer **32**, between the second insulative layer **32** and the second conducting oxide layer **232**, and between the second conducting oxide layer **232** and the first conducting oxide layer **230** for the light reflected by the reflection structure **22** toward the light-emitting stack **25**.

In another embodiment, a thickness of the insulative structure **3** is less than  $\frac{1}{5}$  of a thickness of the transparent conducting structure **23** to prevent a planarization process for planarizing the transparent conducting structure **23** from damaging the insulative structure **3**. The insulative structure **3** is substantially fully covered by the second conducting oxide layer **232** such that the second conducting oxide layer **232** provides strong adhesion force joining to the window layer **29** so as to enhance mechanical strength. In another embodiment, the transparent conducting structure **23** is omitted between the insulative structure **3** and the reflection structure **22**, and therefore, the insulative structure **3** is directly join to the reflection structure **22** for preventing an connecting interface of the reflection structure **22** and transparent conducting structure **23** from peeling because of poor adhesion force between the insulative structure **3** and the transparent conducting structure **23**. The transparent conducting structure **23** fills the multiple pores **242** to from an ohmic contact with the window layer **29**. The transparent conducting structure **23** is transparent to light emitted from the light-emitting stack **25**. Additionally, the transparent conducting structure **23** and the reflection structure **22** together form an omni-directional reflector (ODR) for perfectly reflecting the light emitted from the light-emitting

stack **25**. The material of the first conducting oxide layer **230** and the second conducting oxide layer **232** comprises indium tin oxide (ITO), indium oxide (InO), tin oxide (SnO), cadmium tin oxide (CTO), antimony tin oxide (ATO), aluminum zinc oxide (AZO), zinc tin oxide (ZTO), gallium zinc oxide (GZO), indium tungsten oxide (IWO), zinc oxide (ZnO), indium cerium oxide (ICO), indium tungsten oxide (IWO), indium titanium oxide (ITiO), indium zinc oxide (IZO), indium gallium oxide (IGO), gallium aluminum zinc oxide (GAZO), or a combination thereof. Therefore, even if the light emitted from the light-emitting stack **25** is not reflected by the total-internal-reflection (TIR) interface between the first insulative layer **31** and the window layer **29**, the light can be reflected by the omni-directional reflector (ODR) made from the transparent conducting structure **23** and the reflection structure **22** so the light extraction efficiency of the light-emitting element **100** is increased.

The reflection structure **22** has a reflectivity over 90% for the light emitted from the light-emitting stack **25**, and the material of the reflection structure **22** can be metal material including, but not limited to copper (Cu), aluminum (Al), tin (Sn), gold (Au), silver (Ag), lead (Pb), titanium (Ti), nickel (Ni), platinum (Pt), tungsten (W) or an alloy thereof. The reflection structure **22** includes a reflection layer **226**, an adhesion layer **224** below the reflection layer **226**, a barrier layer **222** below the adhesion layer **224**, and an ohmic contact layer **220** below the barrier layer **222**. The reflection layer **226** can reflect light emitted from the light-emitting stack **25**. The adhesion layer **224** adheres to the reflection layer **226** and the barrier **222**. The barrier layer **222** can prevent the material of the reflection layer **226** from diffusing to the ohmic contact layer **220** and lowering the reflectivity of the reflection layer **226**. The ohmic contact layer **220** forms an ohmic contact with the conducting adhesive layer **21**. The conducting adhesive layer **21** connects to the substrate **20** and the reflection structure **22** and includes a plurality of sub-layers (not shown in figures), wherein the plurality of sub-layers can be made of transparent conducting material or metal material. The transparent conducting material comprises indium tin oxide (ITO), indium oxide (InO), tin oxide (SnO), cadmium tin oxide (CTO), antimony tin oxide (ATO), aluminum zinc oxide (AZO), zinc tin oxide (ZTO), gallium zinc oxide (GZO), zinc oxide (ZnO), gallium phosphide (GaP), indium cerium oxide (ICO), indium tungsten oxide (IWO), indium titanium oxide (ITiO), indium zinc oxide (IZO), indium gallium oxide (IGO), gallium aluminum zinc oxide (GAZO), or a combination thereof. The metal material comprises copper (Cu), aluminum (Al), tin (Sn), gold (Au), silver (Ag), lead (Pb), titanium (Ti), nickel (Ni), platinum (Pt), tungsten (W), or an alloy made of the above mentioned.

The substrate **20** can support the light-emitting stack **25** and be made of a conducting material. For example, the conducting material comprises metal, such as copper (Cu), aluminum (Al), molybdenum (Mo), tin (Sn), zinc (Zn), cadmium (Cd), nickel (Ni) and cobalt (Co), carbon compound, such as diamond like carbon (DLC), graphite and carbon fiber, composite, such as metal matrix composite (MMC), ceramic matrix composite (CMC), or semiconductor, such as silicon (Si), zinc selenide (ZnSe), gallium arsenide (GaAs), silicon carbide (SiC), gallium phosphide (GaP), gallium arsenide phosphide (GaAsP), indium phosphide (InP), LiGaO<sub>2</sub> and LiAlO<sub>2</sub>.

The principle and the efficiency of the present application illustrated by the embodiments above are not the limitation of the application. Any person having ordinary skill in the art can modify or change the aforementioned embodiments.

## 11

Therefore, the protection range of the rights in the application will be listed as the following claims.

What is claimed is:

1. A light-emitting element, comprising:
  - a light-emitting stack comprising an active layer for emitting a light;
  - a window layer on the light-emitting stack; and
  - a first insulative layer having a first refractive index on the window layer;
 wherein the window layer has a second refractive index, and a difference between the first refractive index and the second refractive index is larger than 1.5,
 wherein, from a cross section of the light-emitting element, the window layer has a surface contacting a first surface of the first insulative layer and a ratio of a surface area of the first surface of the first insulative layer to a surface area of the surface of the window layer is between 0.5-0.9.
2. The light-emitting element of claim 1, wherein the first insulative layer comprises a compound of group IIA or a compound of group VILA.
3. The light-emitting element of claim 2, wherein the first insulative layer comprises magnesium fluoride.
4. The light-emitting element of claim 1, wherein the first refractive index is smaller than the second refractive index.
5. The light-emitting element of claim 4, wherein the first refractive index is equal to or smaller than 1.4.
6. The light-emitting element of claim 1, further comprising a transparent conducting structure on the first insulative layer.
7. The light-emitting element of claim 6, wherein the first insulative layer comprises multiple pores, and the transparent conducting structure directly contacting the surface of the window layer through the multiple pores.
8. The light-emitting element of claim 7, wherein the transparent conducting structure having a second surface contacting the surface of the window layer, and a ratio of a

## 12

surface area of the second surface of the transparent conducting structure to the surface area of the surface of the window layer is between 0.1250.25.

9. The light-emitting element of claim 6, wherein a thickness of the first insulative layer is less than a half of a thickness of the transparent conducting structure.

10. The light-emitting element of claim 6, wherein the transparent conducting structure comprises a first conducting oxide layer and a second conducting oxide layer, and the second conducting oxide layer is between the first insulative layer and the first conducting oxide layer, and the first conducting oxide layer has a refractive index smaller than a refractive index of the second conducting oxide layer.

11. The light-emitting element of claim 10, wherein the third refractive index is between 2 and 2.2, and the fourth refractive index is between 1.8 and 2.1.

12. The light-emitting element of claim 10, wherein the second conducting oxide layer has a thickness between 1 nm and 1  $\mu$ m and the first conducting oxide layer has a thickness between 10 nm and 1  $\mu$ m.

13. The light-emitting element of claim 7, wherein one of the multiple pores has a length or a diameter between 2  $\mu$ m and 20  $\mu$ m.

14. The light-emitting element of claim 7, further comprising an electrical contact layer on the light-emitting stack opposite to the first insulative layer, and the electrical contact layer does not overlap the multiple pores from a top view of the light-emitting element.

15. The light-emitting element of claim 7, wherein a top-view shape of one of the multiple pores comprises a polygon or a circle.

16. The light-emitting element of claim 6, further comprising a reflection structure on the transparent conducting structure, a substrate on the reflection structure, and a conducting adhesive layer connecting the substrate to the reflection structure.
