(57) **ABSTRACT**

In general, techniques are described that enable crowdsourcing of product-related information. Product-related information may include availability and intra-store locations of various products at particular stores. An example system includes an interface, a memory, and one or more programmable processors configured to receive, at the interface an intra-store product location from a first client device, the intra-store product location indicating a location of a product within a store. The programmable processor(s) are further configured to store, to at least one storage device coupled to the system and in association with the product, the received intra-store product location, receive, at the interface, a request associated with the product from a second client device, and send, from the interface, the intra-store product location to the second client device in response to receiving the request associated with the product.

COMPUTER-ASSISTED SHOPPING AND PRODUCT LOCATION

This application claims the benefit of U.S. Provisional Application No. 61/723,528, filed Nov. 7, 2012, the entire content of each of which being incorporated herein by reference.

TECHNICAL FIELD

The present disclosure generally relates to the collection and collaborative use of product data.

BACKGROUND

Consumers purchase various products via retail stores. More specifically, retail stores represent the final point of sale (“POS”) before an end-user gains possession of a product. To this end, retail stores often stock and sell a wide variety of products, thus catering to broad customer demands.

Often, multiple consumers, such as members of a single family, may pool their consumer needs together, in order to more efficiently fill those needs. In turn, pooling consumer needs in this manner can result in a single shopper attempting to fill diverse consumer needs during a single visit to a retail store.

SUMMARY

In general, techniques of this disclosure are directed to sharing, or “crowdsourcing” product information pertaining to various products available through retail store locations. In various implementations, the techniques enable a shopping assistant system to collect and catalog information pertaining to the availability of products at various retail store locations. In some implementations, the techniques enable the shopping assistant system to gather intra-store location information for a product (e.g., aisle numbers, shelving levels, etc.).

The techniques of this disclosure may also enable one or more computing devices to collect, aggregate, and transmit shopping list information. For instance, a server implementing the techniques may receive, from various client devices, designations of products that users of the client devices intend to purchase. In turn, the server is configured or otherwise operable to update a shopping list, and provide the updated shopping list, in real-time, to users of the various client devices. The techniques of this disclosure may be implemented in systems that include various computing devices, such as servers and multiple client devices. Additionally, the techniques may incorporate such functionalities as barcode reading and data synchronization through so-called “cloud computing.”

In one example, a method includes receiving, by one or more processors, an intra-store product location from a first client device, the intra-store product location indicating a location of a product within a store and storing, by the one or more processors to at least one storage device and in association with the product, the received intra-store product location. The method further includes receiving, by the one or more processors, a request associated with the product from a second client device, and sending, by the one or more processors, the intra-store product location to the second client device in response to receiving the request associated with the product.

In another example, a shopping assistant system includes an interface, a memory, and one or more programmable processors. The programmable processor(s) are configured to receive, at the interface, an intra-store product location from a first client device, the intra-store product location indicating a location of a product within a store, and store, to at least one storage device coupled to the shopping assistant system, the received intra-store product location. The programmable processor(s) are further configured to receive, at the interface, a request associated with the product from a second client device, and send, from the interface, the intra-store product location to the second client device in response to receiving the request associated with the product.

In another example, a computer-readable storage device is encoded with instructions. The instructions, when executed, cause one or more programmable processors of a computing device to perform operations. The operations include receiving an intra-store product location from a first client device, the intra-store product location indicating a location of a product within a store and storing, to a storage device and in association with the product, the received intra-store product location. The operations further include receiving a request associated with the product from a second client device, and sending the intra-store product location to the second client device.

In another example, a method includes sending, by a client device to a shopping assistant system, a request associated with a product, receiving, by the client device from the shopping assistant system in response to the request, availability information and information indicating whether an intra-store product location is available for the product at a store, and sending, by the client device to the shopping assistant system in response to receiving the information indicating whether an intra-store product location is available, an updated intra-store product location, the updated intra-store product location for the product.

In another example, a client device includes an interface, a memory, and one or more programmable processors. The programmable processor(s) are configured to send, from the interface to a shopping assistant system, a request associated with a product, receive, at the interface from the shopping assistant system in response to the request, availability information and information indicating whether an intra-store product location is available for the product at a store, and send, from the interface to the shopping assistant system in response to receiving the information indicating whether an intra-store product location is available, an updated intra-store product location, the updated intra-store product location for the product.

The techniques of this disclosure provide one or more potential advantages. As one example, when implemented across a server-client network architecture, the techniques may enable consumers to more efficiently locate products within a retail store location, which otherwise may be a time-consuming process. As another example, systems implementing the techniques are updated dynamically, through the collection and processing of data from various consumers who patronize the retail store locations. By collecting and processing data in real-time, the systems are able to crowdsource voluminous data and present consumers with accurate, up-to-date product location information.

Additionally, by consolidating shopping list information received from various sources and distributing the consolidated shopping list information, the techniques enable users of multiple client devices to collaborate in updating the shopping list and access information that is updated in

real-time. For instance, a user who is at or nearing a store location may use a mobile computing device, such as a mobile phone, to view a shopping list that was recently updated by a family member, from a home location, to include additional items for purchase. As another potential advantage, the techniques may enable users to update the shopping list (e.g., populate or depopulate items) by using various computing devices to scan barcodes, RFID tags, universal product codes (UPCs), and other information affixed to the items, using devices such as mobile phones and tablet computers that may be equipped with or coupled to image capture devices, such as cameras.

The details of one or more examples of the disclosure are set forth in the accompanying drawings and the description below. Other features, objects, and advantages of the disclosure will be apparent from the description and drawings, and from the claims.

BRIEF DESCRIPTION OF DRAWINGS

FIG. 1 is a conceptual diagram illustrating an example system in which one or more computing devices may implement shopping assistance techniques, in accordance with various aspects of this disclosure.

FIG. 2 is a block diagram illustrating further details of one example implementation of the shopping assistant system illustrated in FIG. 1

FIG. 3 is a conceptual diagram illustrating an example of a store location at which one or more of mobile devices may implement the intra-store product location techniques of this disclosure.

FIG. 4 is a conceptual diagram illustrating details of a graphical user interface (GUI) provided at a mobile device described with respect to FIGS. 1 & 3.

FIG. 5 is a flowchart illustrating an example process by which a shopping assistant system may, in conjunction with multiple client devices, implement one or more crowdsourcing techniques of this disclosure.

DETAILED DESCRIPTION

FIG. 1 is a conceptual diagram illustrating an example system 100 in which one or more computing devices may implement shopping assistance techniques, in accordance with various aspects of this disclosure. In the example of system 100, a server 110 is communicatively coupled to various devices over network 104. Although in the specific example of FIG. 1, server 110 is illustrated as being communicatively coupled to a specific set of computing devices, namely mobile devices 116A-116N (“mobile devices 116”) and computing device 124 (in this case a personal computer, e.g., a laptop computer at home location 106), it will be appreciated that server 110 may communicate with any number of computing devices (of various types) over network 104 in implementing the techniques of this disclosure. While server 110 is illustrated in FIG. 1 as a single device for ease of illustration purposes only, it will be appreciated that in various implementations, server 110 may include a number of devices, such as processing units, network interfaces, and storage devices. Additionally, various computing resources and functionalities provided by server 110 may be co-located and/or distributed across different locations.

Additionally, FIG. 1 illustrates various store locations 102A-102N (“store locations 102”). Each of store locations 102 represents a distinct point-of-sale (“POS”) location, where consumers can purchase one or more items. Based on a specific store entity associated with each of store locations

102, each respective location of store locations 102 may offer different products (or ranges of products) for sale. For example, if store location 102A is a department store, then store location 102 is likely to offer a broad range of products for sale. Conversely, if store location 102B is a specialty store, then store location 102B is likely to offer a narrower selection of products, but a greater variety of each available type of product. As a result, a consumer may be able to fill varying purchasing needs at each of store locations 102.

Mobile devices 116 may each include, be, or be part of various types of devices, such as a mobile phone (including so-called “smartphones”), a personal digital assistant (“PDA”), or a tablet computer. Mobile devices 116 may provide a user interface (UI), e.g., a display, input media, and a graphical user interface (GUI), by which a consumer may interact with the mobile device. In some examples, a consumer may input or view product information via the user interface provided by the mobile device. In various implementations, one or more of mobile devices 116 are configured or otherwise operable to capture and interpret various types of machine-readable codes, such as barcodes, universal product codes (UPCs), electronic product codes (EPCs) as provided by radio frequency identification (RFID), or quick response (QR) code. For example, in implementations where one or more of mobile devices 116 is equipped with a camera, those particular devices of mobile devices 116 may use the respective cameras to capture a UPC affixed to a product. The mobile device may match the captured UPC or other code to a product identification, e.g., using product tracking software installed on or otherwise accessible (via server 110, for example) to one or more of mobile devices 116.

While all of mobile devices 116 are illustrated in FIG. 1 as being at store location 102A for ease of illustration purposes only, it will be appreciated that various devices of mobile devices 116 may be at store location 102A at different times. For instance, mobile device 116A may, at a given point of time, be the only device of mobile devices 116 that is at store location 102A. At a subsequent point of time, mobile device 116B may be the only device of mobile devices 116 that is at store location 102A.

Computing device 124 at home location 106 may be any type of computing device. Computing device 124 may take the form of a laptop or other personal computer at home location, although computing device may be a mobile device that is located at home location 106 or otherwise not within a store location 102. Computing device 124 may include a UI, which may include a display, input media, and a GUI. A consumer, e.g., at home location 106, may enter and view product information, e.g., a product description, via the UI provided by computing device 124. As shown in FIG. 1, server 110 includes control unit 112. Control unit 112, in various examples, includes any combination of one or more processors, one or more field programmable gate arrays (FPGAs), one or more application specific integrated circuits (ASICs), and one or more application specific standard products (ASSPs). Control unit 112 may also comprise memory, both static (e.g., hard drives or magnetic drives, optical drives, FLASH memory, EPROM, EEPROM, etc.) and dynamic (e.g., RAM, DRAM, SRAM, etc.), or any other non-transitory computer readable storage medium capable of storing instructions that cause the one or more processors to perform the techniques described in this disclosure. Thus, control unit 112 may represent hardware or a combination of hardware and software to support the below described components, modules or elements, and the techniques should not be strictly limited to any particular example

described below. Additionally, in various examples, functionalities described with respect to server **110** and/or shopping assistant system **114** may be implemented by control unit **112** or components thereof, such as by one or more processors of server **110**.

As shown, control unit **112** provides shopping assistant system **114**. Shopping assistant system **114** is configured or otherwise operable to implement various techniques described herein. In some implementations, shopping assistant system **114** is operable to receive product-identifying information from one or both of mobile devices **116** and computing device **124** to populate and/or depopulate a shopping list. Additionally, in some implementations, shopping assistant system **114** is operable to sync shopping list information, such that the shopping list is available a number of users using various devices, such as to users of both mobile devices **116** and computing device **124**.

Groups of consumers, such as members of a family or other organization, may share, update, and monitor purchasing needs according to one or more techniques of this disclosure using devices such as computing device **124** and mobile devices **116**. By entering product-identifying information at one or more of mobile devices **116** and/or computing device **124**, the consumers of the group are able to collectively document future purchasing needs, or that certain needed items have been purchased. As one example, the consumers may use shopping list software accessible to mobile device **116A** and/or computing device **124** to add and remove items for purchase. In one implementation, mobile device **116A** and computing device **124** may access and utilize shopping list software provided by server **110**.

For example, shopping assistant system **114** may receive product-identifying information from computing device **124** (which is at home location **106**) to populate the shopping list. Independent of the populating operation, shopping assistant system **114** may receive product-identifying information from mobile device **116A** to depopulate the shopping list. More specifically, a user of computing device **124** may add an item to be purchased, while a user of mobile device **116A** removes an item from the list (e.g., by scanning the UPC of an item recently selected for purchase at store location **102A**). In turn, shopping assistant system **114** dynamically updates the shopping list, providing real-time shopping list information to users of mobile device **116A** and computing device **124**. In this manner, shopping assistant system **114** is operable to consolidate purchasing information across multiple users and provide the users with a consolidated, up-to-date shopping list.

In some scenarios, the user of a mobile device **116** may encounter difficulties in locating a particular product within store location **102A**. As described, depending on the size, layout, and other characteristics of store location **102A**, a user may expend substantial time and energy to discern the intra-store location (e.g., aisle and/or shelf number) of a particular product within store location **102A**. In various implementations, shopping assistant system **114** is operable to collect, store, and modify intra-store location information of particular items.

For instance, if the user of mobile device **116A** locates a particular product and scans the UPC code, shopping assistant system **114** is operable to discern the intra-store location of the scanned product. Shopping assistant system **114** may discern the intra-store location using a variety of data, such as GPS coordinates transmitted by mobile device **116A**, triangulation information associated with wireless access points deployed at store location **102A**, or ZigBee® network information available at store location **102A**. In some

examples, e.g., if shopping assistant system **114** is not otherwise able to access to the intra-store location of a scanned product, shopping assistant system **114** causes mobile device **116A** to prompt the user to enter the intra-store location. In some examples, shopping assistant system **114** causes mobile device **116A** to prompt a user to enter an aisle number, a shelf number, and other related information with regards to the scanned product. In turn, shopping assistant system **114** is configured to save the intra-store location of the scanned product, either locally at server **110**, or at a remote location accessible to server **110** (e.g., through cloud-computing methods). In some implementations, mobile device **116A** is configured to locally store, or cache, the intra-store location of one or more scanned products. For instance, mobile device **116A** may store the intra-store location(s) to one or more storage device included in mobile device **116A**. By caching the intra-store location of various products (such as frequently purchased products), mobile device **116A** may provide convenient access to the intra-store locations. For instance, a user's access to a product's intra-store location may not be encumbered by unreliability of a network connection over which mobile device **116A** communicates with shopping assistant system **114**.

Additionally, shopping assistant system **114** may provide enhanced product information as part of the consolidated shopping list through inclusion of intra-store locations of various products in the list. For example, if another consumer adds a particular product to a shopping list, shopping assistant system **114** may draw on the previously acquired intra-store location of the product to assist the consumer. For example, shopping assistant system **114** may provide the intra-store location of the product to the consumer responsive to an indication that the user is at store location **102A**. Shopping assistant system **114** may determine that the consumer is at store location **102A** based on various data, such as GPS coordinates transmitted from the consumer's mobile computing device, a wireless network identifier detected by the mobile computing device, and the like.

Similarly, shopping assistant system **114** may continue to receive updates and/or clarifications on intra-store location information of a product. For example, a subsequent scan of a product using mobile device **116B** may indicate a different intra-store location from the currently saved intra-store location information. In this scenario, shopping assistant system **114** is operable to update the intra-store location based on the updated information received from mobile device **116B**. As another example, shopping assistant system **114** may have partial information associated with the intra-store location of a product (e.g., the aisle number, but not the shelf number). In this example, shopping assistant system **114** is operable to complete the available intra-store location information based on data subsequently received from mobile device **116B** or another device at store location **102A**. In this manner, shopping assistant system **114** implements the techniques of this disclosure to aggregate (or "crowdsource") information provided by various users and/or devices for the benefit of users during future visits to a particular store location.

FIG. 2 is a block diagram illustrating further details of one example implementation of shopping assistant system **114** illustrated in FIG. 1. In general, shopping assistant system **114** includes one or more computing devices (e.g., computing servers that provide operating environments for various software modules). These servers can generally be categorized as web servers **20**, application servers **21**, communication servers **36**, and database servers **42**. Although these servers are illustrated separately in FIG. 2, shopping assis-

tant system **114** may, in various implementations, be realized by a single computing device, or a plurality of cooperating computing devices, as the case may be.

Web servers **20** provide an interface by which one or more authorized users **15**, e.g., consumers, communicate with shopping assistant system **114** via network **104**. In one configuration, web servers **20** execute web server software (such as software marketed by Microsoft® Corporation under the trade designation “INTERNET INFORMATION SERVICES” or formerly under the trade designation “INTERNET INFORMATION SERVER”). As such, web servers **20** provide an environment for interacting with remote user(s) **15** according to user interface modules **29**, which can include Active Server Pages, web pages written in hypertext markup language (HTML) or dynamic HTML, Active X modules, Lotus scripts, Java scripts, Java Applets, Distributed Component Object Modules (DCOM) and the like.

Although illustrated as “server side” software modules executing within an operating environment provided by web server **20**, user interface modules **29** could readily be implemented as “client-side” software modules executing on computing devices, such as mobile devices **116** and computing device **124** of FIG. 1, used by one or more remote users. User interface modules **29** could, for example, be implemented as Active X modules executed by a web browser for execution on the remote computing devices.

Communication servers **36** provide an operating environment for various interfaces and/or modules that provide the ability to establish direct connections with one or more remote devices (such as mobile devices **116** and computing device **124**) and/or disparate data systems of various enterprises (such as store locations **102**, suppliers). In this manner, shopping assistant system **114** can automatically interact with mobile devices **116** and/or systems deployed at various locations, such as store locations **102**. As shown in FIG. 2, network interface module **40**, while operating within an environment provided by communication servers **36**, may enable shopping assistant system **114** to communicate over network **104**, e.g., with mobile devices **116** and computing device **124**.

Application servers **21** provide an operating environment for application software modules **23**, which provide the underlying logic and functionality for implementing the various techniques ascribed to shopping assistant system **114** herein. Message dispatcher **34** receives communications from communication servers **36**, and issues inbound messages **45A** to application software modules **23** to process the communications. In particular, communication servers **36** may receive, using network interface module **40**, communications from remote devices, and, in turn, forward the communications to message dispatcher **34**. Message dispatcher **34** determines the appropriate application software modules **23** for processing each communication, and dispatches one or more inbound message **45A** to the identified modules. In a similar manner, application software modules **23** may generate outbound messages **45B** to communicate with remote devices over network **104**.

Application software modules **23** may include a number of modules including product ID module **28**, store ID module **22**, client location module **26**, intra-store location module **30**, shopping list module **24**, and code translation module **32**. Application software modules **23** interact with database servers **42** to access a number of data stores **44**, including product data **44A**, availability data **44B**, intra-store location data **44C**, code data **44D**, and shopping list state data **44E**. Data stores **44** may be implemented in a

number of different forms including data storage files, or as a database management system (DBMS). The database management system may be a relational (RDBMS), hierarchical (HDBMS), multidimensional (MDBMS), object oriented (ODBMS or OODBMS) or object relational (ORDBMS), or other database management system. Furthermore, although illustrated separately, data stores **44** could be combined into a single database or other data storage structure. Data stores **44** could, for example, be implemented as a single relational database (such as that marketed by Microsoft® Corporation under the trade designation “SQL SERVER”).

In general, product ID module **28** handles and/or processes identification of various products that a consumer may add to or remove from a shopping list. For instance, product ID module **28** may receive, as part of inbound messages **45A**, an identification of a product (e.g., for purposes of inventory or to determine an intra-store location of the identified product). In turn, product ID module **28** may map the product identification included in inbound messages **45A** to data stored as part of product data **44A**. Based on the mapping, product ID module **28** may supply product information, such as a description, or an alternate product if the identified product is unavailable, via outbound messages **45B** to communication servers **36**. In instances where product ID module **28** identifies an alternate product, product ID module **28** may apply criteria such as product preferences and/or dietary restrictions supplied by a user, and availability of coupons or other discounted options at a particular store location. Additionally, product ID module **28** may generate alternate store suggestions where the product may be available (e.g., based on proximity to the current location of the mobile computing device).

Intra-store location module **30**, in various implementations, is configured or otherwise operable to receive, update, and map intra-store locations of products to product IDs. As described with respect to FIG. 1, shopping assistant system **114** may receive intra-store location information of various products, e.g., from mobile devices **116** via network **104**. In such examples, intra-store location module **30** may access and modify information that is stored as part of data stores **44**, such as intra-store location data **44C**. Additionally, intra-store location module **30** may map various portions of intra-store location data **44C** to one or more of product data **44A** and shopping list state data **44E**, the latter of which is described in more detail below. In some examples, intra-store location module **30** may determine a particular product’s intra-store location based on location data that is received with product ID data as part of incoming messages **45A**. As noted, intra-store location module **30** may continually receive and update intra-store location data **44C** using input from multiple client devices, thus crowdsourcing diverse information and providing up-to-date intra-store location information in real time.

Store ID module **22** of shopping assistant system **114** is configured or otherwise operable to receive and interpret identifications of specific stores, such as one or more of store locations **102** illustrated in FIG. 1. As one example, store ID module **22** may receive, as part of inbound messages **45A**, a designation of a store at which a client device, such as mobile device **116A**, is located. Based on the particular store location identified by the client device, store ID module **22** may access various information from data stores **44**, such as product data **44A** corresponding to the store location and, in some instances, availability data **44B** pertaining to product data **44A** at the identified store location.

As shown in FIG. 2, application modules 23 may also include shopping list module 24. In various implementations, shopping list module 24 is configured or otherwise operable to populate and depopulate a shopping list for a consumer (or group of consumers) based on information received from client devices via network 104. In certain specific examples, shopping list module 24 may update information included in data stores 44, such as shopping list state data 44E, in order to populate or depopulate the shopping list. For instance, shopping list module 24 may add a product identification (or alternatively, generate a reference, such as a pointer, to a product identification in product data 44A) in response to receiving a request to add a product to a shopping list. Conversely, shopping list module 24 may remove a product identification (or alternatively, delete a reference to a product identification in product data 44A) in response to receiving a request to remove an item from the shopping list. As noted, shopping list module 24 may populate and depopulate the shopping list based on requests received from diverse client devices, thereby enabling collaborative updating of shopping list information by consumers who share common purchasing needs.

Client location module 26 of shopping assistant system 114 is configured or otherwise operable to discern a location of a client device, such as mobile device 116A. In some examples, store ID module 22 may not receive an explicit designation of a particular store location at which mobile device 116A is located. In such instances, client location module 26 use various data included in inbound messages 45A, such as GPS coordinates transmitted by mobile device 116A or SSIDs of wireless network connections accessible to mobile device 116A, to discern that mobile device 116A is at or near a particular store location. In some instances, client location module 26 may include, as part of outgoing messages 45B, a list of possible store locations that a consumer using mobile device 116A may visit (e.g., if client location module 26 detects that mobile device 116A is positioned near a mall or other shopping complex).

As shown, application modules 23 may also include code translation module 32. Code translation module 32 may receive, as part of inbound messages 45A, information pertaining to barcodes, UPCs, and other machine-readable codes. For instance, a consumer may use a camera of mobile device 116A to scan a barcode affixed to a product, and transmit the barcode (and/or related information) via network 104 to shopping assistant system 114. In turn, code translation module 32 may use code data 44D to discern a product identified by the code (e.g., using a lookup table that maps code data 44D to product data 44A). In this manner, application modules 23, such as code translation module 32, product ID module 28, and intra-store location module 30, may share collaboratively map information received via inbound messages 45A for efficient data retrieval and generation.

FIG. 3 is a conceptual diagram illustrating an example of a store location 102A at which one or more of mobile devices 116 may implement the intra-store product location techniques of this disclosure. FIG. 3 illustrates details of an example layout of store location 102A described above with respect to FIG. 1. Also, as described with respect to FIG. 1, consumers may, at various times, avail of functionalities provided by one or more of mobile devices 116 while at store location 102A. For instance, a consumer may use mobile device 116A to access an updated shopping list, and depopulate the list as the consumer collects items for purchase (e.g., by scanning a barcode affixed to the item using a camera of mobile device 116A). Additionally, one or more

of mobile devices 116 may enable a user to access shopping list information stored remotely (e.g., at server 110 of FIG. 1). For instance, mobile devices 116 may provide a user with access to the location of a particular product within store location 102A. By providing a user with intra-store locations of various products included in the shopping list, mobile devices 116 may increase efficiency (e.g., by reducing any time the user would spend looking for the product, or time that the user would spend in traveling to another of store locations 102 if the user fails to locate the product on his/her own at store location 102A).

As shown in FIG. 3, store location 102A may include several aisles 1-N (hereinafter, "aisles"). Additionally, a party, such as a retail chain that operates store location 102A, may arrange various products according to the aisles. In the example of FIG. 3, first item 306 and second item 308 are placed in a top shelf and a bottom shelf, respectively, of aisle 1. Similarly, third item 310 and fourth item 312 are placed in a top shelf and a bottom shelf, respectively, of aisle N. While FIG. 3 illustrates two shelves per aisle, with a single item placed on each shelf for ease of illustration purposes only, it will be appreciated that a store location may include aisles with any number of shelves, and various products may be placed on a given shelf.

In some scenarios, a consumer using mobile device 116A may enter store location 102A. Upon entering store location 102A, the consumer may use mobile device 116A to access a shopping list that includes various items, such as first item 306 and third item 310. Based on information collected previously (e.g., via mobile devices used by consumers who previously visited store location 102A), the shopping assistant system may provide, via the shopping list, information associated with third item 310, such as the intra-store location of item 310.

For instance, the shopping assistant system may determine that mobile device 116A is at or near store location 102A (e.g., based on GPS coordinates transmitted by mobile device 116A, by triangulating the location of mobile device 116A using cellular communication towers and/or wireless access points, by detecting one or more SSIDs identified by mobile device 116A, etc.). Upon detecting that mobile device 116A is at or near store location 102A, the shopping assistant system may provide, via the shopping list, information pertaining to the availability and/or intra-store location of third item 310 at store location 102A. In the particular example illustrated in FIG. 3, the shopping assistant system may indicate, via the shopping list, that third item 310 is available at store location 102A, and that third item 310 is located in the top shelf of aisle N.

In contrast, the shopping assistant system may not have any information pertaining to the availability or intra-store location of first item 306 at store location 102A. In this instance, the consumer using mobile device 116A may, on his/her own, locate first item 306, and remove first item 306 from the shopping list (e.g., by scanning a barcode affixed to first item 306 using mobile device 116A or by providing a user input at mobile device 116A to remove first item 306 from the shopping list). Based on the removal of first item 306 from the shopping list while mobile device 116A is at store location 102A, the shopping assistant system may determine that first item 306 is available at store location 102A, and update the availability information pertaining to first item 306 accordingly. In turn, the shopping assistant system may provide the availability information to consumers who subsequently visit store location 102A, such as a user of mobile device 116B. In this manner, the shopping assistant system may implement the techniques of this

disclosure to collect and disseminate product-related information to consumers using mobile devices **116** at various times, effectively crowdsourcing the product-related information.

In the example described, the shopping assistant system may not obtain intra-store location information for first item **306**. The intra-store location of first item **306** may be absent from the transmitted information for various reasons, such as an inability of mobile device **116A** to discern the intra-store location (e.g., due to a lack of GPS connectivity), or the consumer's choice not to provide the intra-store location via user input. In this example, the shopping assistant system may, via the shopping list, inform the user of mobile device **116B** that first item **306** is available at store location **102A**. However, the shopping assistant system may not provide any supplemental information, such as the intra-store location of first item **306**, via the shopping list to the user of mobile device **116B**. In various implementations, mobile device **116B** may receive availability information including data that indicates a previous (e.g., a last-known, last-reported, or last-recorded) intra-store location of the product.

Upon locating first item **306** within store location **102A**, the user of mobile device **116B** may remove first item **306** from the shopping list, such as by using mobile device **116B** to scan a barcode affixed to first item **306**. In this example, mobile device **116B** may identify or approximate the location of first item **306** (e.g., using GPS coordinates or by triangulating the location using wireless access points deployed at store location **102A**), and determine that first item **306** is located at aisle **1** within store location **102A**. In turn, client-side software executing on mobile device **116B** may transmit the intra-store location of first item **306** (namely, aisle **1**) to the shopping assistant system. In this example, mobile device **116B** may transmit the aisle number but no further intra-store location information, such as a shelf number associated with first item **306**, to the shopping assistant system.

At a subsequent time, a consumer using mobile device **116C** for shopping list purposes may enter store location **102A**. Additionally, the current shopping list for the user of mobile device **116C** may include first item **306**. In this example, mobile device **116C** may display, via a client-side shopping list application, availability and intra-store location information pertaining to first item **306**. More specifically, in this instance, the shopping assistant system may indicate, via the shopping list application executing on mobile device **116C**, that first item **306** is available at store location **102A**, and that first item **306** is located in aisle **1**.

However, in this instance, the shopping assistant system may not provide any additional information, such as a shelf number associated with first item **306**, to the user of mobile device **116C**. In turn, the user of mobile device **116C**, upon locating first item **306** within aisle **1**, may provide additional information, such as the location of first item **306** in the top shelf of aisle **1**, to the shopping assistant system via mobile device **116C**. As a result, future consumers (e.g., who use one or more of mobile devices **116**) who visit store location **102A** and use the shopping assistant system for shopping list purposes, may have access to the aisle and shelf number of first item **306** within store location **102A**. In this manner, the shopping assistant system may implement the techniques of this disclosure to crowdsource (e.g., collect and dynamically supplement) product-related information to benefit subsequent consumers at a given store location.

While the example described above illustrates the implementation of the crowdsourcing techniques of this disclosure

with respect to a single iteration of adding product-related information, it will be appreciated that the techniques may also be implemented to modify and/or update product-related information. For example, if a retail chain or other party operating store location **102A** relocates a product, such as first item **306**, to a different aisle and/or shelf, the shopping assistant system may collect and update the intra-store location information for first item **306** (e.g., via automatic detection and transmission by mobile devices **116** or user input entered at mobile devices **116**). In examples, the shopping assistant system may utilize date- and/or time-stamps in determining which information is current, thus providing up-to-date product-related information to users of mobile devices **116** in real time. For instance, the shopping assistant system may execute one or more algorithms that use date- and/or time-stamps as parameters. The executed algorithm(s) may employ one or both of voting-based and authority-based techniques, which in turn may weight particular data based on reliability scores associated with particular users, take into account recent tendencies in location reporting, cross-check incoming data for statistical consistency, etc.

As illustrated in FIG. 3, in some examples, a store location may include a local database that may store product location information. For instance, store location **102A** includes local database **314**. Mobile devices **116** may communicate with local database **314** through a variety of channels (e.g., using a wireless access point or other communication medium deployed at store location **102A**). Local database **314** may serve as an alternative and/or a supplement to remote devices (such as server **110** of FIG. 1) that implement the shopping assistant system techniques described herein. By storing product location information at (and making the product location information available through) local database **314**, an administrator of store location **102** may provide potential advantages, such as backing up store product location information in case of a data loss at the remote device, and providing the information via a faster and/or more dependable connection (e.g., WiFi® as opposed to cellular data services). In various implementations, local database **314** may include product IDs and intra-store locations of products available at store location **102A** and/or at other store locations (e.g., at other stores operated by the same company as store location **102**). Functionalities described herein with respect to shopping assistant systems may be provided by one or more of local database **314** and various remote devices, either singly or in any combination.

FIG. 4 is a conceptual diagram illustrating details of a graphical user interface (GUI) **400** provided at mobile device **116A** described with respect to FIGS. 1 & 3. GUI **400** includes GUI elements such as scan button **408** and item indicators **404A-404D** (item indicators **404**). Additionally, FIG. 4 illustrates camera lens **406**, which may serve as an interface to a camera (e.g., a front-facing camera) of mobile device **116A**. In various examples, GUI **400** may be generated for display by client-side software executing on mobile device **116A** that implements one or more shopping assistance techniques of this disclosure.

As shown in FIG. 4, the shopping assistant system that supplies shopping list information to mobile device **116A** may have access and/or provide varying levels of information pertaining to different items. As some specific examples, item indicators **404** display varying levels of information pertaining to the availability and/or intra-store locations of various items at a given store location (e.g., store location **102A** described with respect to FIGS. 1 & 3).

Item indicator **404A** includes an exclamation mark (“!”) to indicate a shopping list addition that a user of mobile device **116A** has not yet viewed, or is viewing for the first time since opening the current instance of the shopping assistant client software on mobile device **116A**. Additionally, item indicator **404A** includes a notification that the item was added by “Alice” at 4:15 pm of the current day. For purposes of example, Alice may be a user of a computing device positioned remotely from mobile device **116A**, such as computing device **124** positioned at home location **106** in FIG. 1. Item indicator **404A** illustrates the real-time updating and cloud-based syncing of shopping list information carried out when implementing one or more techniques of this disclosure. Additionally, item indicator **404A** includes the intra-store location of the item, including both the aisle and shelf number.

In contrast, item indicators **404B-404D** do not include the exclamation mark to indicate that the user of mobile device **116A** has not yet viewed them. Additionally, item indicator **404B** includes partial intra-store location information, namely, the aisle number of the item. However, item indicator **404B** includes a notification that the shopping assistant system does not currently have access to the shelf number associated with the respective item. Based on the partial intra-store location information included in item indicator **404B**, a consumer may infer availability information of the item (specifically, that the item is available) at the current store location.

Item indicator **404C** includes availability information of an item, but does not include any intra-store location information pertaining to the item at the current store location. As the shopping assistant system does not currently provide any intra-store location information for the item, the shopping assistant system (through server software, client software, etc.) causes item indicator **404C** to explicitly notify a user that the item is available at the current store location. In contrast, item indicator **404D** includes a notification that the shopping assistant system has neither availability nor intra-store location information pertaining to the respective item at the current store location.

As shown, both of item indicators **404C** & **404D** include a request for the user to scan and/or input a location of the respective items, if the user locates the items at the current store location. In one example, the user may actuate scan button **408** and scan a barcode affixed to a located item by placing the barcode in the line of sight of camera lens **406**. In various implementations, the client-side software of the shopping assistant system may modify GUI **402** to present the user with one or more options, such as options to add the scanned item to the shopping list, to remove the scanned item from the shopping list, or to scan additional instances of the item in response to a greater requested quantity of the item.

Additionally, the shopping assistant system may determine or approximate the intra-store location of the item (e.g., using one or more techniques enumerated above) and/or prompt the user to provide the intra-store location information via user input via GUI **402**. Based on data received via these techniques, the shopping assistant system may record and/or update the intra-store location information for each item. Additionally, the shopping assistant system may record a timestamp associated with each update of the intra-store location. As shown in FIG. 4, the shopping assistant system may display timestamp-related information via GUI **402** (e.g., item indicator **404B** indicates that the availability and/or intra-store location information of the item was last updated two weeks prior to a current date).

FIG. 5 is a flowchart illustrating an example process **500** by which a shopping assistant system may, in conjunction with multiple client devices, implement one or more crowd-sourcing techniques of this disclosure. Although process **500** may be performed by any device or combination of devices described herein, for purposes of clarity only, process **500** is described herein with respect to shopping assistant system **114** (implemented on server **110**) and mobile devices **116** of FIG. 1.

Process **500** may begin when mobile device **116A** uploads an item ID and a store ID to server **110** (**502**). While illustrated as a single step for ease of illustration purposes only, it will be appreciated that mobile device **116A** may upload an item ID and a store ID at different times. Additionally, mobile device **116A** may upload more than one item ID for a given store ID, e.g., in instances where a consumer using mobile device **116A** scans more than one item at store location **102A**, on one or more visits to store location **102A**. It will also be appreciated that mobile device **116A** may upload the store ID of store location **102A** by active and/or passive means.

One example of actively uploading the store ID includes receiving, at a user interface such as GUI **402** provided at mobile device **116A**, a user input that indicates that mobile device **116A** is at store location **102A**. In this example, mobile device **116A** may upload, to server **110**, the store ID of store location **102A** based on the received user input. In contrast, an example of passively uploading the store ID may include periodically or constantly transmitting, by mobile device **116A**, one or more of GPS coordinates or SSIDs associated with mobile device **116A**. As further examples of passively uploading the store ID, shopping assistant system **114** and/or other components of server **110** may periodically poll the location of mobile device **116A**, such as by triangulating the location of mobile device **116A** using cellular communication towers in the vicinity of mobile device **116A**.

Shopping assistant system **114** may receive and save the item ID and the store ID uploaded by mobile device **116A** (**504**). As one example, shopping assistant system **114** may not receive any intra-store product location information pertaining to the identified item at store location **102A**. In this instance, shopping assistant system **114** may save availability information associated with the identified item at store location **102A** (e.g., that the identified item is available at store location **102A**).

At another time, such as subsequently to a consumer using mobile device **116A** visiting store location **102A**, a consumer using mobile device **116B** may enter store location **102A**. Additionally, a shopping list created and/or accessed by the consumer may include the item identified earlier by mobile device **116A**. Using mobile device **116B**, the consumer may request, from shopping assistant system **114**, the intra-store product location of the identified item within store location **102A** (**506**).

As described above with respect to the upload of the store ID by mobile device **116A**, mobile device **116B** may request the intra-store product location of the identified item by active and/or passive means. As an example of a passive request, mobile device **116B** may request the intra-store product location by virtue of the identified item being included in the shopping list accessed by mobile device **116B**. In turn, shopping assistant system **114** may receive, from mobile device **116B**, the request for the intra-store product location of the identified item (**508**) and transmit, to mobile device **116B**, a notification indicating that the intra-

15

store product location of the identified item is currently unavailable to shopping assistant system **114** (**510**).

Mobile device **116B** may receive the notification from shopping assistant system **114** indicating that the intra-store product location of the identified item is currently unavailable through shopping assistant system **114** (**512**). At this point, the consumer using mobile device **116B** may have access to information regarding the availability of the identified item at store location **102A** (e.g., based on the availability information uploaded from mobile device **116A** to shopping assistant system **114** in **502**). In response, the consumer, upon locating the identified item at store location **102A**, may use mobile device **116B** to scan a barcode and/or UPC affixed to the identified item, and upload the intra-store product location of the identified item (**514**). As described, the consumer using mobile device **116B** may either enter the intra-store product location of the identified item, or mobile device **116B** may automatically approximate the intra-store product location before uploading to shopping assistant system **114**.

In turn, shopping assistant system **114** may receive and save the intra-store product location information for the identified item (**516**). In the specific example described with respect to process **500**, shopping assistant system **114** receives identifications of an item and a store, as well as availability information for the item at the store, from mobile device **116A**. At a subsequent time, shopping assistant system **114** supplies the availability information to mobile device **116B**. Responsive to a request from mobile device **116B** for the intra-store product location of the identified item at the store, shopping assistant system **114** notifies mobile device **116B** that the intra-store product location is currently unavailable.

In response to the received notification mobile device **116B** (either through user input or through automatic response), uploads intra-store product location information for the identified item within the identified store location. In turn, shopping assistant system **114** supplements the availability information for the identified item with the received intra-store product location information.

The example of process **500** illustrates a shopping assistant system may implement the techniques of this disclosure to crowdsource information gathered from various client devices over time to provide robust product-related information to subsequent consumers. When implemented iteratively over time, the shopping assistant system may continually update and fine-tune the information based on the most recent available information. In this manner, techniques of this disclosure may enable a shopping assistant system to use crowdsourcing to generate and distribute more complete, robust, and up-to-date product-related information to multiple consumers, thereby assisting the users to more easily and efficiently purchase the items.

Techniques described herein may also be embodied or encoded in an article of manufacture including a computer-readable storage medium encoded with instructions. Instructions embedded or encoded in an article of manufacture including an encoded computer-readable storage medium, may cause one or more programmable processors, or other processors, to implement one or more of the techniques described herein, such as when instructions included or encoded in the computer-readable storage medium are executed by the one or more processors. Computer-readable storage media may include random access memory (RAM), read only memory (ROM), programmable read only memory (PROM), erasable programmable read only memory (EPROM), electronically erasable programmable

16

read only memory (EEPROM), flash memory, a hard disk, a compact disc ROM (CD-ROM), a floppy disk, a cassette, magnetic media, optical media, or other computer readable media. Additional examples of computer readable medium include computer-readable storage devices, computer-readable memory, and tangible computer-readable medium. In some examples, an article of manufacture may comprise one or more computer-readable storage media.

In some examples, computer-readable storage media and/or computer-readable storage devices may comprise non-transitory media and/or non-transitory devices. The term “non-transitory” may indicate that the storage medium is tangible and is not embodied in a carrier wave or a propagated signal. In certain examples, a non-transitory storage medium may store data that can, over time, change (e.g., in RAM or cache).

Various examples have been described. These and other examples are within the scope of the following claims.

What is claimed is:

1. A method comprising:

updating, by one or more processors, a crowd-sourced database, the crowd-sourced database comprising information about a plurality of products, information about a plurality of stores, and a plurality of shopping lists, wherein the updating of the crowd-sourced database is comprised of:

receiving, by the one or more processors, a request to add a product of the plurality of products to a shopping list of the plurality of shopping lists,

storing, by the one or more processors to at least one storage device and in association with the shopping list,

identifying information for the product, and identifying information for other products of the plurality of products,

receiving, by the one or more processors, an intra-store product location from a first client device, the intra-store product location indicating a location of the product within a store of the plurality of stores, and storing, by the one or more processors to the at least one storage device and in association with the product and the store, the received intra-store product location of the product; and

providing, by the one or more processors, data from the crowd-sourced database, wherein the providing of the data from the crowd-sourced database is comprised of:

receiving, by the one or more processors, from a second client device, a request to access the shopping list, detecting, by the one or more processors, that the second client device is at or near the store, and

sending, by the one or more processors, in response to the receiving of the request to access the shopping list and the detecting that the second client device is at or near the store, an updated version of the shopping list to the second client device, comprising the updated version of the shopping list including:

the identifying information for the product and the intra-store product location, wherein the identifying information for the product and the intra-store product location are associated with one another in the updated version of the shopping list, and identifying information for the other products of the plurality of products.

2. The method of claim **1**, wherein detecting that the second client device is at or near the store further comprises:

17

receiving, by the one or more processors and from the second client device, one or more location coordinates associated with the second client device; and comparing the location coordinates associated with the second client device to one or more location coordinates associated with the store. 5

3. The method of claim 1, wherein detecting that the second client device is at or near the store further comprises: triangulating, by the one or more processors, a position of the second client device; and 10 comparing the triangulated position of the second client device to one or more location coordinates associated with the store.

4. The method of claim 1, further comprising: 15 subsequent to sending the identifying information for the product and the intra-store product location to the second client device, receiving, by the one or more processors and from the second client device, an updated intra-store product location associated with the product, the updated intra-store product location being different from the intra-store product location; and 20 storing, by the one or more processors to at least one storage device, the updated intra-store product location in place of the intra-store product location. 25

5. The method of claim 4, further comprising: receiving, by the one or more processors, a request associated with the product from a third client device; and 30 sending, by the one or more processors, the updated intra-store product location to the third client device.

6. The method of claim 5, wherein receiving the request associated with the product from the third client device further comprises: 35 receiving a request to add the product to a shopping list from the third client device.

7. The method of claim 6, wherein receiving the request associated with the product further comprises: 40 receiving a machine-readable code associated with the product; and mapping the machine-readable code to an identification of the product.

8. The method of claim 1, wherein the updated version of the shopping list includes, in association with one or more of the other products, one or more indicators selected from the group consisting of: 45 a indication of when a was added to the shopping list, an indication of whom added a product to the shopping list, and an indication of a product not being carried at the store. 50

9. The method of claim 1, wherein the updated version of the shopping list includes: 55 a indication of when a product of the other products was added to the shopping list, an indication of whom added a product of the other products to the shopping list, and an indication of a product of the other products not being carried at the store.

10. A shopping assistant system comprising: 60 an interface; a memory; and one or more programmable processors configured to update a crowd-sourced database, the crowd-sourced database comprising information about a plurality of products, information about a plurality of stores, and a plurality of shopping lists, wherein the one or more programmable processors being configured to update 65

18

the crowd-sourced database is comprised of the one or more programmable processors being configured to: receive, at the interface, a request to add a product of the plurality of products to a shopping list of the plurality of shopping lists, store, to at least one storage device coupled to the shopping assistant system and in association with the shopping list, 5 identifying information for the product, and identifying information for other products of the plurality of products, receive, at the interface, an intra-store product location from a first client device, the intra-store product location indicating a location of the product within a store of the plurality of stores, and 10 store, to the at least one storage device coupled to the shopping assistant system and in association with the product and the store, the received intra-store product location of the product;

wherein the one or more programmable processors are further configured to provide data from the crowd-sourced database, and the one or more programmable processors being configured to provide the data from the crowd-sourced database is comprised of the one or more programmable processors being configured to: receive, at the interface, from a second client device, a request to access the shopping list, 15 detect that the second client device is at or near the store, and send, from the interface, in response to receiving the request to access the shopping list and detecting that the second client device is at or near the store, an updated version of the shopping list to the second client device, comprising the updated version of the shopping list including: 20 the identifying information for the product and the intra-store product location, wherein the identifying information for the product and the intra-store product location are associated with one another in the updated version of the shopping list, and identifying information for the other products of the plurality of products.

11. The shopping assistant system of claim 10, wherein the storage device is positioned at the store, and wherein the storage device comprises a local database associated with the store. 25

12. The shopping assistant system of claim 10, wherein the one or more programmable processors are further configured to: 30 subsequent to sending the identifying information for the product and the intra-store product location to the second client device, receive, at the interface and from the second client device, an updated intra-store product location associated with the product, the updated intra-store product location being different from the intra-store product location; and store, to the storage device coupled to the shopping assistant system, the updated intra-store product location in place of the intra-store product location. 35

13. A computer-readable storage device encoded with instructions that, when executed, cause one or more programmable processors of a computing device to perform operations comprising: 40 updating a crowd-sourced database, the crowd-sourced database comprising information about a plurality of products, information about a plurality of stores, and a

19

plurality of shopping lists, wherein the updating of the crowd-sourced database is comprised of:

receiving a request to add a product of the plurality of products to a shopping list of the plurality of shopping lists, 5

storing to at least one storage device and in association with the shopping list, identifying information for the product, and

identifying information for other products of the plurality of products, 10

receiving an intra-store product location from a first client device, the intra-store product location indicating a location of the product within a store of the plurality of stores, and

storing, to the at least one storage device and in association with the product and the store, the received intra-store product location of the product; and 15

providing data from the crowd-sourced database, wherein the providing of the data from the crowd-sourced database is comprised of: 20

receiving, from a second client device, a request to access the shopping list,

detecting that the second client device is at or near the store, and 25

sending, in response to the receiving of the request to access the shopping list and the detecting that the second client device is at or near the store, an updated version of the shopping list to the second client device, comprising the updated version of the shopping list including: 30

the identifying information for the product and the intra-store product location, wherein the identifying information for the product and the intra-store product location are associated with one another in the updated version of the shopping list, and 35

identifying information for the other products of the plurality of products.

14. A method comprising:

updating, by one or more processors, a crowd-sourced database, the crowd-sourced database comprising information about a plurality of products, information about a plurality of stores, and a plurality of shopping lists, wherein the updating of the crowd-sourced database is comprised of: 40

receiving, by the one or more processors, a request to add a product of the plurality of products to a shopping list of the plurality of shopping lists, 45

storing, by the one or more processors to at least one storage device and in association with the shopping list, 50

identifying information for the product, and

identifying information for other products of the plurality of products,

receiving, by the one or more processors, an intra-store product location from a first client device, the intra-store product location indicating a location of the product within a store of the plurality of stores, and 55

storing, by the one or more processors to the at least one storage device and in association with the product and the store, the received intra-store product location of the product; 60

providing, by the one or more processors, data from the crowd-sourced database, wherein the providing of the data from the crowd-sourced database is comprised of: 65

receiving, by the one or more processors, from a second client device, a request to access the shopping list,

20

detecting, by the one or more processors, whether the second client device is at or near the store,

sending, by the one or more processors, in response to the receiving of the request to access the shopping list and the detecting that the second client device is at or near the store, an updated version of the shopping list to the second client device, comprising the updated version of the shopping list including: 5

the identifying information for the product and the intra-store product location, wherein the identifying information for the product and the intra-store product location are associated with one another in the updated version of the shopping list, and

identifying information for the other products of the plurality of products;

subsequent to sending the updated version of the shopping list to the second client device, receiving, by the one or more processors and from the second client device, an updated intra-store product location associated with the product, the updated intra-store product location being different from the intra-store product location; and

storing, by the one or more processors to the at least one storage device, the updated intra-store product location in place of the intra-store product location.

15. The method of claim 14, wherein detecting whether the second client device is at or near the store further comprises:

receiving, by the one or more processors and from the second client device, one or more location coordinates associated with the second client device; and

comparing the location coordinates associated with the second client device to one or more location coordinates associated with the store.

16. The method of claim 14, wherein detecting whether the second client device is at or near the store further comprises:

triangulating, by the one or more processors, a position of the second client device; and

comparing the triangulated position of the second client device to one or more location coordinates associated with the store.

17. The method of claim 14, further comprising:

receiving, by the one or more processors, a request associated with the product from a third client device; and

sending, by the one or more processors, the updated intra-store product location to the third client device.

18. The method of claim 17, wherein receiving the request associated with the product further comprises:

receiving a machine-readable code associated with the product; and

mapping the machine-readable code to an identification of the product.

19. A shopping assistant system comprising:

an interface;

a memory; and

one or more programmable processors configured to update a crowd-sourced database, the crowd-sourced database comprising information about a plurality of products, information about a plurality of stores, and a plurality of shopping lists, wherein the one or more programmable processors being configured to update the crowd-sourced database is comprised of the one or more programmable processors being configured to:

receive, at the interface, a request to add a product of the plurality of products to a shopping list of the plurality of shopping lists,

21

store, to at least one storage device coupled to the shopping assistant system and in association with the shopping list,
 identifying information for the product, and
 identifying information for other products of the plurality of products,
 receive, at the interface, an intra-store product location from a first client device, the intra-store product location indicating a location of the product within a store of the plurality of stores, and
 store, to the at least one storage device positioned at the store and coupled to the shopping assistant system and in association with the product, the received intra-store product location of the product, wherein the storage device comprises a local database associated with the store;
 wherein the one or more programmable processors are further configured to provide data from the crowd-sourced database, and the one or more programmable processors being configured to provide the data from the crowd-sourced database is comprised of the one or more programmable processors being configured to:
 receive, at the interface, from a second client device, a request to access the shopping list;
 detect that the second client device is at or near the store, and
 send, from the interface, in response to receiving the request to access the shopping list and detecting that the second client device is at or near the store, an updated version of the shopping list to the second client device, comprising the updated version of the shopping list including:
 the identifying information for the product and the intra-store product location, wherein the identifying information for the product and the intra-store

22

product location are associated with one another in the updated version of the shopping list, and identifying information for the other products of the plurality of products;
 wherein the one or more programmable processors being configured to update the crowd-sourced database is further comprised of the one or more programmable processors being configured to:
 subsequent to sending the identifying information for the product and the intra-store product location to the second client device, receive, at the interface and from the second client device, an updated intra-store product location associated with the product, the updated intra-store product location being different from the intra-store product location, and
 store, to the at least one storage device coupled to the shopping assistant system, the updated intra-store product location in place of the intra-store product location.
20. The shopping assistant system of claim **19**, wherein the one or more programmable processors are further configured to:
 receive, at the interface, a request associated with the product from a third client device; and
 send, from the interface, the updated intra-store product location to the third client device.
21. The shopping assistant system of claim **20**, wherein the request associated with the product comprises:
 receiving a machine-readable code associated with the product; and
 mapping the machine-readable code to an identification of the product.
