TELECOMMUNICATIONS PANEL**

CROSS-REFERENCE TO RELATED
APPLICATION(S)

This application is a National Stage of PCT/EP2014/055390, filed 18 Mar. 2014 and claims benefit of U.S. Patent Application Ser. No. 61/803,313 filed on 19 Mar. 2013 and U.S. Patent Application Ser. No. 61/913,083 filed on 06 Dec. 2013, and which applications are incorporated herein by reference. To the extent appropriate, a claim of priority is made to each of the above disclosed applications.

TECHNICAL FIELD

The present invention relates to telecommunications panels and cable bend control guides, patch cord supports, and hinges adapted to be used in various telecommunications panels.

BACKGROUND

Numerous telecommunications panels exist today and are used in various equipment applications. Conventional telecommunications panels include hinges that are designed to allow a tray to be rotated out of the telecommunications panel. By rotating the tray out of the telecommunications panel, access is provided to rear portions of a termination field. Such trays may include cable management structures that aid in organizing and managing telecommunications cables routed to and away from the telecommunications panel.

SUMMARY

In this disclosure, a telecommunications arrangement includes a base body, a termination field pivotally coupled to the base body, and a guide member coupled to the base body independent of the termination field. The base body defines an interior accessible through an open front that extends between a first side and a second side. The termination field couples to the base body to pivot relative to the base body along a path of travel between a first position and a second position. The termination field extends across the open front when in the first position provides access to the open front when in the second position. The guide member is coupled to the base body to provide bend radius protection to cables plugged into the termination field. The guide member is configured to pivot relative to the base body and to pivot relative to the termination field. The guide member defines a channel leading the cables from the termination field towards the first side of the base body at an exterior of the base body.

In certain examples, the guide member does not extend across any optical adapters of the termination field. In certain examples, the guide member is coupled to the base body at a front corner of the base body. In certain examples, the termination field includes at least one row of optical adapters. In examples, the termination field includes multiple rows of optical adapters. In certain examples, the guide member defines a single channel. In other examples, the guide member defines multiple channels.

In some implementations, the termination field pivots about a first axis and the guide member pivots about a second axis that is spaced from the first axis. In other

2

implementations, the termination field and the guide member pivot about a common axis.

In some implementations, the termination field is configured to pivot with the guide member relative to the base body as the termination field pivots along a first portion of the path of travel; and to pivot relative to the guide member as the termination field pivots along a second portion of the path of travel. In other implementations, the guide member pivots relative to the termination field to compensate for changes in a route length along which the optical cables extend.

In some implementations, a base body holds one termination field and one guide member. In other implementations, a base body can hold a plurality of termination fields and a plurality of guide members.

In an example, the base body includes an enclosure body and the termination field is carried by a door that opens and shuts the enclosure body. In another example, the base body includes a chassis and the termination field is carried by a tray that pivots into and out of the chassis.

In some implementations, a telecommunications panel includes a chassis, a tray rotatably mounted to the chassis by a hinge, and a guide member rotatably mounted to the chassis. The tray is moveable in and out of the chassis. The guide member is adapted to provide bend radius protection to cables routed to the telecommunications panel.

In other implementations, a telecommunications panel includes a chassis, a pin mounted to the chassis, and a tray rotatably mounted to the chassis by a hinge. The tray is moveable in and out of the chassis. The hinge includes a sleeve of the tray mounted about the pin. The sleeve is removable from the pin without removing the pin from the chassis. The tray is removable from the chassis by removing the sleeve from the pin.

In other implementations, a method of using a telecommunication panel includes: 1) providing the telecommunication panel with a chassis, a tray, a hinge, and a guide member; 2) moving the tray between an installed configuration and an access configuration by rotating the hinge; 3) rotating the guide member while moving the tray; and 4) providing bend radius protection to cables routed to the telecommunications panel with the rotating guide member.

In other implementations, an enclosure defines an access opening for accessing an interior of the enclosure. A door and guide members are pivotally mounted to the enclosure at the access opening. The door pivots along a path of travel to at least partially close the access opening when in a closed position and to allow access to the enclosure interior through the access opening when in an open position. The guide members move with the door relative to the enclosure when the door moves along a first portion of the path of travel. The guide members stop moving relative to the enclosure at an intermediate position along the path of travel. The door is configured to move relative to the guide members and the enclosure as the door moves along a second portion of the path of travel.

In certain examples, the door is configured to hold one or more optical adapters. In other examples, the door is configured to hold value-added modules (VAMs) that include optical adapters. In still other examples, the door is configured to hold electrical jacks.

A variety of additional inventive aspects will be set forth in the description that follows. The inventive aspects can relate to individual features and to combinations of features. It is to be understood that both the forgoing general description and the following detailed description are exemplary

and explanatory only and are not restrictive of the broad inventive concepts upon which the embodiments disclosed herein are based.

BRIEF DESCRIPTION OF THE DRAWINGS

The accompanying drawings, which are incorporated in and constitute a part of the description, illustrate several aspects of the present disclosure. A brief description of the drawings is as follows:

FIG. 1 is a perspective view of an example telecommunications panel including a cable guide member providing moveable bend control and patch cord support according to the principles of the present disclosure;

FIG. 2 is an enlarged portion of FIG. 1;

FIG. 3 is the perspective view of FIG. 1, but with a cover of the telecommunications panel removed;

FIG. 4 is a portion of the perspective view of FIG. 3, but with a tray rotated out of an interior of the telecommunications panel;

FIG. 5 is the perspective view of FIG. 4, but with a cable management structure of the tray rotated upward;

FIG. 6 is an enlarged portion of FIG. 5;

FIG. 7 is a top plan view of the telecommunications panel of FIG. 1 with the tray of FIG. 4 rotated out of the interior;

FIG. 8 is an enlarged portion of FIG. 7;

FIG. 9 is the top plan view of FIG. 7, but with the tray of FIG. 4 rotated into the interior;

FIG. 10 is the top plan view of FIG. 9, but with a cut-away revealing the interior of the telecommunications panel;

FIG. 11 is a perspective view of the cable guide member of FIG. 1;

FIG. 12 is another perspective view of the cable guide member of FIG. 1;

FIG. 13 is a bottom plan view of the cable guide member of FIG. 1;

FIG. 14 is a front elevation view of the cable guide member of FIG. 1;

FIG. 15 is a first side elevation view of the cable guide member of FIG. 1;

FIG. 16 is a second side elevation view of the cable guide member of FIG. 1;

FIG. 17 is a perspective view of a chassis suitable for use with the telecommunications panel of FIG. 1 with a tray structure of a tray suitable for use with the telecommunications panel of FIG. 1 positioned to be snapped over a mounting pin of the chassis;

FIG. 18 is the perspective view of FIG. 17, but with the tray structure snapped over the pin;

FIG. 19 is the perspective view of FIG. 18, but with the tray structure rotated into an interior of the chassis;

FIG. 20 is a partial perspective view of another telecommunications panel including rotatable cable guide members according to the principles of the present disclosure;

FIG. 21 is another partial perspective view of the telecommunications panel of FIG. 20, but with one of the rotatable cable guide members rotated and a tray rotated partially out of an interior of the telecommunications panel;

FIG. 22 is still another partial perspective view of the telecommunications panel of FIG. 20, but with the one of the rotatable cable guide members of FIG. 21 further rotated and with the tray of FIG. 21 rotated out of the interior of the telecommunications panel;

FIG. 23 is yet another partial perspective view of the telecommunications panel of FIG. 20 with the one of the rotatable cable guide members of FIG. 21 further rotated and

with the tray of FIG. 21 rotated out of the interior of the telecommunications panel, as in FIG. 22;

FIG. 24 is a front perspective view of an example enclosure including a door in a closed position relative to the enclosure;

FIG. 25 is another perspective view of an example enclosure of FIG. 24;

FIG. 26 is a perspective view of the enclosure of FIG. 24 with the door in an open position so that the interior of the enclosure is visible;

FIG. 27 is another perspective of the enclosure of FIG. 26 rotated so that guide members are visible;

FIG. 28 is a perspective view of enlarged portions of the enclosure and door of FIG. 27;

FIG. 29 is another perspective view of the enclosure of FIG. 24 with the door in an intermediate position relative to the enclosure;

FIGS. 30 and 31 are perspective views of the enclosure of FIG. 26 with components including the door and guide members exploded away from the enclosure;

FIG. 32 is a perspective view of an example cabinet system configured to hold one or more of the enclosures of FIGS. 24-31; and

FIG. 33 is a perspective view of an example rack system configured to hold one or more of the enclosures of FIGS. 24-31.

DETAILED DESCRIPTION

Reference will now be made in detail to exemplary aspects of the present disclosure that are illustrated in the accompanying drawings. Whenever possible, the same reference numbers will be used throughout the drawings to refer to the same or similar parts.

In this disclosure, a telecommunications arrangement includes a base body, a termination field pivotally coupled to the base body, and a guide member coupled to the base body independent of the termination field. The base body defines an interior accessible through an open front. The termination field couples to the base body to pivot relative to the base body along a path of travel between a first position and a second position. The termination field extends across the open front when in the first position provides access to the open front when in the second position. The guide member is coupled to the base body to provide bend radius protection to cables plugged into the termination field. The guide member is configured to pivot relative to the base body and to pivot relative to the termination field. The guide member defines a channel leading the cables from the termination field to an exterior of the base body.

In some implementations, the open front extends between a first side and a second side of the base body; and the channel of the guide member routes the cables towards the first side of the base body.

FIGS. 1-33 illustrate example telecommunications arrangements. In some implementations, the termination field of the telecommunications arrangement can be carried by a tray that pivots into and out of a base body (e.g., see FIGS. 1-23). In other implementations, the termination field of the telecommunications arrangement can be carried by a door that opens and closes a base body (e.g., see FIGS. 24-33). In still other implementations, the termination field of the telecommunications arrangement can be otherwise carried by another pivotal member that mounts to a base body.

FIGS. 1-23 illustrate an example telecommunications arrangement including a telecommunications panel 100

(e.g., an enclosure, an optical distribution frame, etc.) configured according to the principles of the present disclosure. As illustrated at FIG. 3, the telecommunications panel 100 may be included in a cabinet 200. The telecommunications panel 100 and/or the cabinet 200 may be used for various purposes in telecommunications systems. For example, patch cords 18 (i.e., patch cables, connectorized fiber optic cables, etc.) may enter the telecommunications panel 100 and/or the cabinet 200 and be interconnected at a termination field 120. The termination field 120 may include a plurality of fiber optic adapters 126. Fiber optic connectors that terminate ends of the patch cords 18 may connect with the fiber optic adapters 126 of the termination field 120. The interconnections at the termination field 120 may be rearranged from time-to-time, as desired, for changing configurations of the telecommunications system. The telecommunications panel 100 may further hold splitters, filters, and various other telecommunications components.

The telecommunications panel 100 may include a chassis 10, a tray 20 (e.g., a sub-rack), and a hinge 50. The hinge 50 includes a pin 30 and a sleeve 40 that are arranged and configured to couple to one another (see FIG. 10). As depicted, the hinge 50 connects the tray 20 to the chassis 10 and defines a vertical hinge with an axis A2 for the telecommunications panel 100. As depicted, the tray 20 includes the sleeve 40 and the tray 20 rotates with the sleeve 40 about the axis A2 thereby creating a pivot. As illustrated at FIGS. 17 and 21, the pin 30 may be mounted to the chassis 10 with suitable fasteners. The chassis 10 may include a base 12 and a top 16 that each include mounting tabs 17 with attachment points (e.g., fastener holes) for attaching the pin 30 (see FIG. 17). The tray 20 and, in particular, the sleeve 40 may be trapped between the mounting tabs 17 of the top 16 and the base 12 of the chassis 10. As depicted, in certain embodiments multiple trays 20 may be stacked upon one another and mounted about the pin 30. The trays 20 may be independently rotatable about the axis A2 and may be rotated separately or together about the pin 30.

As depicted at FIG. 1, the chassis 10 extends between opposing sides 14. The hinge 50 is mounted adjacent a hinge side 14h of the opposing sides 14. The patch cords 18 extend from the termination field 120 and are routed adjacent the hinge side 14h and/or through the cabinet 200. When the tray 20 is rotated between an installed configuration 26 (see FIGS. 1, 3, 9, and 10) and an access configuration 28 (see FIGS. 4-8) the patch cords 18 are guided by a guide member 105. As depicted, a plurality of the guide members 105 is illustrated with each of the guide members 105 corresponding to one of the trays 20. The guide members 105 are rotatable about an axis A4 (see FIG. 2). The axis A4 is spaced away from the axis A2 in the depicted embodiments. In other embodiments, the axis A2 and A4 may be colinear with each other.

The guide members 105 are rotatable guide members that serve to guide the patch cords 18 when the tray 20 is moved between the installed configuration 26 and the access configuration 28. The guide members 105 further support the patch cords 18 when the tray 20 is at the installed configuration 26, the access configuration 28, and between the installed configuration 26 and the access configuration 28. As depicted, the guide members 105 guide the patch cords 18 that are routed to the termination field 120 of the tray 20 that corresponds to the guide member 105. As one of the trays 20 is rotated between the installed configuration 26 and the access configuration 28, only the guide member 105 that corresponds with the one of the trays 20 need rotate about

the axis A4. Other of the guide members 105 corresponding to the trays 20 that remain stationary may also remain stationary.

The guide members 105 may cooperate with corresponding guide members 110 that are mounted to and move with the tray 20. As depicted, the tray 20 includes two of the guide members 110 that generally move with the tray 20 as it is moved between the installed configuration 26 and the access configuration 28. Some of the patch cords 18 are routed through two of the guide members 110. Others of the patch cords 18 are routed through one of the guide members 110. Still others of the patch cords 18 are not routed through the guide members 110. In particular, terminal locations on the termination field 120 farther from the axis A2 may have a corresponding one of the patch cords 18 routed through multiple guide members 110. Terminal locations on the termination field 120 nearer to the axis A2 may have a corresponding one of the patch cords 18 directly routed to the guide members 105.

Guide members 115 adjacent the hinge side 14h of the telecommunications panel 100 and/or the cabinet 200 may further cooperate with the guide members 105. As illustrated at FIG. 4, one of the guide members 115 is positioned at the hinge side 14h of the telecommunications panel 100 and cooperates with the guide member 105. The guide members 115 may be mounted to the telecommunications panel 100 (e.g., the chassis 10) and/or the cabinet 200. The guide members 115 may remain stationary with the telecommunications panel 100 (e.g., the chassis 10).

The guide members 105, 110, and 115 thereby may form a guide member system wherein a first portion of the patch cords 18 are guided and held relative to the tray 20, a second portion of the patch cords 18 are held and guided relative to the chassis 10, and a third portion, between the first portion and the second portion, is held and guided by the independently rotatable guide member 105.

Some or all of the patch cords 18 may slide along their length within the guide members 105, 110, and/or 115 as the tray 20 is moved between the installed configuration 26 and the access configuration 28.

As the tray 20 is rotated between the installed configuration 26 and the access configuration 28, a route length of the patch cords 18 may change. In particular, the patch cords 18 may generally be around the axis A2 when transitioning from the termination field 120 to the hinge side 14h of the telecommunications panel 100. As a portion of the patch cords 18 arcing around the axis A2 may extend over a greater angle when the tray 20 is at the installed configuration 26 in comparison to the access configuration 28, a greater route length would occur when the tray 20 is at the installed configuration 26. As the tray 20 is rotated toward the access configuration 28, a resulting reduced route length of the patch cords 18 may lead to a bunching of the patch cords 18. The bunching of the patch cords 18 may further lead to buckling of the patch cords 18 and/or otherwise may lead to the patch cords 18 bending sharper than a minimum bend radius of optical fiber within the patch cords 18 specifies.

However, according to the principles of the present disclosure, a position of the axis A4 is selected such that the guide member 105 swings away from the axis A2 and thereby compensates for the otherwise changing route length by adding to the route length when rotated away from the axis A2 and reducing the route length when rotated toward the axis A2. In particular, the guide members 105 are positioned nearer to the axis A2 when the tray 20 is at the installed configuration 26 and rotate away from the axis A2

as the tray 20 is moved toward the access configuration 28. Compensating changes in the route length are thereby reduced and increased by the action of the guide members 105 as they rotate about the axis A4. Overall differences in the route length between the installed configuration 26 and the access configuration 28 may thereby be reduced and/or eliminated.

In the depicted embodiments, the guide members 105 freely rotate about the axis A4 but are urged to a rotational position by the patch cords 18 that are routed through the guide members 105. In particular, an equilibrium position is determined by differential bending of the patch cords 18. The patch cords 18 generally require a greater bending moment to reach a sharper bending radius and a lesser bending moment to reach a gentler bending radius. By routing the patch cords 18 through the guide members 105, and by having the guide members 105 rotatable about the axis A4 that is offset from the axis A2, the guide members 105 are rotationally positioned about the axis A4 at a rotational position that minimizes or at least reduces the bending moments carried by the patch cords 18. By minimizing or at least reducing the bending moments carried by the patch cords 18, the bend radii of the patch cords 18 are maximized or at least enlarged. Bend radius protection is thereby provided by the guide members 105 to the patch cords 18.

In certain embodiments, some or all of the patch cords 18 may slide along their length within the guide members 105, 110, and/or 115. The equilibrium position and/or the bend radius protection may be affected by such sliding. Such sliding may further minimize or at least reduce the bending moments carried by the patch cords 18, and the bend radii of the patch cords 18 may thereby be maximized or at least enlarged. Additional bend radius protection may thereby be provided by the guide members 105, 110, and/or 115 to the patch cords 18.

In addition to bend radius protection, the guide members 105, 110, and/or 115 may prevent the patch cords 18 from tangling and/or mixing with other patch cords 18. Tangling and/or mixing may be prevented between the patch cords 18 corresponding to the same tray 20 and/or between the patch cords 18 of neighboring trays 20.

Turning now to FIGS. 11-16, the guide member 105 will be described in detail. The guide member 105 includes a guide member body 150 that extends between a first side 152 and a second side 154. In the depicted embodiment, the first side 152 corresponds to a top of the guide member 105, and the second side 154 corresponds to a bottom of the guide member 105. The guide member body 150 further includes an inner wall 156 and an outer wall 158. As depicted, the inner wall 156 and the outer wall 158 are formed in a partially cylindrical shape. The partially cylindrical shape of the inner wall 156 may be concentric with the axis A2 when the guide member 105 is positioned at the installed configuration 26 (see FIG. 2). The inner wall 156 may also be concentric with the sleeve 40 and/or the pin 30 when the guide member 105 is at the installed configuration 26.

As illustrated at FIGS. 4, 5, and 20-23, the inner wall 156 and the outer wall 158 facilitate a tangential transitioning of the patch cords 18 from the termination field 120 as the patch cords 18 pass through a cable passage 160 of the guide member body 150. As depicted, the cable passage 160 is formed by the first side 152, the second side 154, the inner wall 156, and the outer wall 158. To install and remove the patch cords 18 from the cable passage 160, a cable insertion slot 162 is provided. The guide member body 150 further includes a hinge portion 170. The hinge portion 170 defines

the axis A4 and is adapted to mount to the chassis 10 of the telecommunications panel 100. In the depicted embodiment, the hinge portion 170 includes a pin hole 172.

As depicted, the cable insertion slot 162 is positioned at the outer wall 158. The cable insertion slot 162 may be curved along an arc. The patch cord 18 may be curved about a similar arc to facilitate passage into and through the cable insertion slot 162. As the direction of bending the patch cord 18 for insertion through the cable insertion slot 162 is generally perpendicular to the bending of the patch cords 18 around the axis A2, the patch cords 18 are retained within the cable passage 160 and are unlikely to accidentally pass through the cable insertion slot 162. To further keep the patch cords 18 installed within the cable passage 160, a keeper 164 is provided along the cable insertion slot 162. The keeper 164 may allow the cable insertion slot 162 to be widened and still provide a restrictive path for the patch cord 18 to be installed into and removed from the cable passage 160.

Turning now to FIG. 2, mounts 180 of the telecommunications panel 100 are illustrated. The mounts 180 are adapted to mount the guide member 105 to the chassis 10. As depicted, the mount 180 includes a pair of arms 182. The pair of arms 182 may each include a pin stub 184. The pin stubs 184 of the pair of arms 182 may face inwardly toward each other. The arms 182 may be flexible and thereby facilitate the insertion of the guide member 105 between the arms 182 by bending the arms 182 outwardly from each other. The pin stubs 184 may further include ramp surfaces which further facilitate the spreading of the arms 182 when the hinge portion 170 of the guide member body 150 is pressed through between the pin stubs 184 and the arms 182. Upon the hinge portion 170 being in position, the pin hole 172 aligns with the pin stubs 184, and the pin stubs 184 insert themselves into the pin hole 172. In particular, the arms 182 urge the pin stubs 184 into the pin hole 172. Upon the guide member 105 being inserted into the mount 180, the guide member 105 is freely rotatable about the axis A4. Removal of the guide member 105 may be accomplished by spreading the arms 182 and reversing the above process.

Turning now to FIGS. 17-19, an alternate embodiment of a sleeve 40' is illustrated according to the principles of the present disclosure. As with the sleeve 40, the sleeve 40' is attached to the tray 20 and rotatably mounts about the pin 30. In the depicted embodiments, the sleeve 40 and the sleeve 40' are one piece with a tray structure 24 of the tray 20. An access slot 42 (i.e., an access cut) is cut through a wall of the sleeve 40'. As depicted, the axis slot 42 is wedge shaped. As depicted, the wedge shape reaches a vertex at the axis A2. The wedge shape may be pressed over the pin 30, and the sleeve 40' may thereby be spread apart and allow the pin 30 to snap within the sleeve 40'.

At FIG. 17, the tray structure 24 is positioned with the axis slot 42 aligned with the pin 30. At FIG. 18, the tray structure 24 has been moved toward the pin 30 and the sleeve 40' has been snapped over the pin 30. The tray structure 24 is thereby mounted to the pin 30 and to the chassis 10'. Upon the mounting of the tray structure 24 to the chassis 10', the tray structure 24 and thereby the tray 20 may be rotated between the installed configuration 26 and the access configuration 28.

To keep the tray 20 at the installed configuration 26, a latch structure 190 may be included in the telecommunications panel 100. In particular, the depicted embodiment includes a latch at the tray structure 24 and a catch at the chassis 10, 10'.

By including the latch structure 190 and the sleeve 40' with the access slot 42, the tray structure 24, and thereby the tray 20, may be installed and removed from the telecommunications panel 100 without tools or at least without special tools. Additional trays 20 may thereby be added to the telecommunications panel 100 and installed trays 20 may thereby be removed from the telecommunications panel 100. By including an easily removable tray 20 in the telecommunications panel 100, assembly of the telecommunications panel 100 is simplified, and investing in additional trays 20 may be deferred until needed.

In certain embodiments, the guide member 105 may allow the tray 20 to open farther than a guide member that is fixed to a conventional tray. In particular, if the guide member is fixed to the conventional tray adjacent to a hinge of the conventional tray, the guide member may interfere with adjacent structure upon the conventional tray being opened. In contrast, the guide member 105 may rotate separately from the tray 20 and may stop rotating upon contact with adjacent structure (e.g., of the cabinet 200) while the tray 20 continues opening. The tray 20 may therefore open farther than the conventional tray, in certain embodiments.

In certain embodiments, the patch cables 18 may be constrained by adjacent structure (e.g., of the cabinet 200). As the guide member 105 may rotate separately from the tray 20, a constraint on the patch cables 18 is removed or at least relaxed. By removing or relaxing this constraint from the patch cables 18, sharp bending of the patch cables 18 can be avoided, even when the patch cables 18 are constrained by the adjacent structure (e.g., when the tray 20 is opened).

FIGS. 24-33 illustrate another example telecommunications arrangement including an enclosure 300 defining an access opening 303 for accessing an interior of the enclosure 300. A door 304 and guide members 305 are pivotally mounted to the enclosure 300 at the access opening 303. The door 304 pivots along a path of travel T to at least partially close the access opening 303 when in a closed position and to allow access to the enclosure interior through the access opening 303 when in an open position. The guide members 305 move with the door 304 relative to the enclosure 300 when the door 304 moves along a first portion of the path of travel T. However, the guide members 305 stop moving relative to the enclosure 300 at an intermediate position along the path of travel T. The door 304 is configured to move relative to the guide members 305 and the enclosure 300 as the door 304 moves along a second portion of the path of travel T.

A feature of the enclosure 300 is that the largest possible opening angle of the door 304 (defined by the path of travel T) is not limited by the largest possible opening angle of the guide members 305. If the guide members 305 were rigidly attached to the door 304, then the guide members 305 would need to move along the complete path of travel T to enable the door 304 to move along the complete path of travel T. Accordingly, any interference between the guide members 305 and the enclosure 300 (or cables routed about the enclosure) would interfere with movement of the door 304. By allowing the door 304 to move relative to the guide members 305, the path of travel T and, hence, the opening angle of the door 304 may be increased.

FIGS. 24 and 25 illustrate one example enclosure 300 including a body 301 defining an interior 302 accessible through an access opening 303. A door 304 is pivotally coupled to the enclosure 300 at the access opening 303. The door 304 is configured to pivot relative to the enclosure 300 between a closed position (see FIG. 24) and an open position (see FIG. 26). When in the closed position, the door 304 at

least partially closes the access opening 303 to inhibit access to the enclosure interior 302. When in the open position, the door 304 enables access to the enclosure interior 302 through the access opening 303.

In some implementations, the door 304 is configured to receive telecommunications components to define a termination field 320. The termination field 320 has front ports 322 (FIG. 27) that face away from the enclosure interior 302 when the door is closed and rear ports 324 (FIG. 26) that face towards the enclosure interior 302 when the door is closed. For example, in certain implementations, the door 304 is configured to hold one or more optical adapters 326. The adapters 326 define the front and rear ports 322, 324. For example, the door 304 can define openings or elongated slots 321 (FIG. 24) in which the optical adapters can mount. SC type adapters is one example for adapters 326. In certain implementations, the door 304 is configured to hold value-added modules (VAMs) that include optical adapters. In other implementations, electrical jacks can be disposed on the door 304.

Telecommunications cables (e.g., optical cables, electrical cables, etc.) enter the enclosure interior 302 and are routed to the rear ports 324 of the termination field 320. For example, the enclosure 300 may define a second access opening 306 (e.g., at a top, bottom, or side of the enclosure 300) through which the cables can enter. In some implementations, additional telecommunications components (e.g., optical splitters, splice trays, wave division multiplexers, etc.) can be disposed within the enclosure interior 302 and connected to the rear ports 324. Additional telecommunications cables (e.g., patch cords) can plug into the front ports 322 of the termination field 320 to connect to the telecommunications cables and/or intermediate cables at the rear ports.

The additional telecommunications cables can be routed away from the enclosure 300 using guide members 305. For example, guide members 305 can be disposed adjacent the pivot axis P of the door 304. In some implementations, the guide members 305 extend forwardly of the door 304 to define slots through which the cables can be routed away from the door 304. In certain implementations, the guide members 305 include bend radius limiters that protect the cables against excessive bending as the cables are routed away from the door 304.

Additional details regarding example enclosures suitable for use with the disclosed door and guide members can be found in U.S. Pat. No. 6,760,531, the disclosure of which is hereby incorporated herein by reference.

In accordance with some aspects of the disclosure, the guide members 305 are configured to move with the door 304 at least part of the way as the door 304 is moved from the closed position to the open position. As the door 304 is moved towards the open position, the guide members 305 pivot away from the access opening 303. In certain implementations, the guide members 305 meet with interference (e.g., with the enclosure 300 or with cables routed about the enclosure 300) at an intermediate point along the path of travel T of the door 304 (see FIG. 29). When interference is met, the guide members 305 stop pivoting relative to the enclosure body 301. However, the door 304 can continue to move along the path of travel T to the open position.

In some implementations, the guide members 305 are configured to pivot about the same pivot axis P as the door 304 (see FIG. 28). For example, the enclosure body 301 includes at least one hinge base 307 that supports a hinge pin 310 adjacent the access opening 303. The hinge pin 310 defines the pivot axis P. The door 304 includes at least one

hinge flange **308** that rotatably engages the hinge pin **310** so that the door **304** pivots about the pivot axis P. The guide members **305** also include a hinge flange **309** that rotatably engages the hinge pin **310** so that the guides **305** pivot about the pivot axis P. The hinge flange **309** of the guide members **305** is separate from the hinge flange **308** of the door **304**. Accordingly, the hinge flanges **308**, **309** can be moved separately.

In certain implementations, the enclosure body **301** includes two hinge bases **307** holding hinge pins **310** at the top and bottom of the enclosure body **301** aligned along the pivot axis P. In such implementations, the door **304** and guides **305** include upper and lower hinge flanges **308**, **309** that rotatably engage the support pins **310** at the hinge bases **307**. The upper and lower hinge flanges **308**, **309** provide stability to the door **304** and guides **305** during rotation. In certain implementations, the door hinge flanges **308** are disposed between the guide member hinge flanges **309** and the hinge bases **307**. In other implementations, however, the guide member hinge flanges **309** can be positioned between the door hinge flanges **308** and the hinge bases **307** or at opposite sides of the hinge bases **307** from the door hinge flanges **308**.

In some implementations, the pivot axis P is disposed within the enclosure interior **302**. In other implementations, however, the pivot axis P is disposed outside of the enclosure interior **302**. For example, as shown in FIGS. **24** and **27**, the pivot axis P is disposed in front and to one side of the door **304**. The hinge bases **307** of the enclosure body **301** extend forwardly of the door **304**. The door hinge flanges **308** also extend outwardly in front of the door **304** when the door **304** is closed. In the example shown, the guide member hinge flange **309** extends laterally outwardly from the guide members **305** in front of the door **304**. Disposing the pivot axis P outside of the enclosure **300** increases the available length of the path of travel T for the door **304**.

As the door **304** and guide members **305** move from the closed position to the open position, the door hinge flanges **308** and the guide member hinge flanges **309** rotate in unison about the hinge pin **310**. When the guide members **305** reach the intermediate position along the path of travel T, however, the door hinge flange **308** begins to rotate relative to the guide member hinge flange **309**. As shown in FIG. **28**, the guide member hinge flange **309** is shaped (e.g., defines a contoured surface **312**) to enable the door **304** to slide or cam around the flange **309** as the door **304** moves relative to the guide member hinge flange **309**.

The hinge flange **309** of the guide members **305** includes an abutment surface **313** that is configured to engage part **304a** (see FIGS. **28** and **29**) of the door **304** when the door **304** is pivoted towards the open position. For example, the door **304** may include a vertically extending flange **304a** that protrudes forwardly of the door **304** when the door **304** is in the closed position. When the door **304** is moved from the closed position towards the open position, the door flange **304a** engages the abutment surface **313** of the guide member hinge flange **309**, thereby entraining the guide members **305** to pivot with the door **304**. When the guide members **305** reach the intermediate position along the path of travel T, further movement of the door **304** causes the door **304** to cam or slide around the contoured surface **312**, thereby moving the door flange **304a** out of engagement with the abutment surface **313**.

The guide members **305** include a tab **315** (FIG. **28**) that extends between the door **304** and the enclosure body **301** adjacent the pivot axis P. The tab **315** moves rigidly with the guide members **305**. When the door **304** moves from the

intermediate position to the open position, the door **304** moves away from the tab **315**. When the door **304** returns to the intermediate position, however, the door **304** engages the tab **315**. As the door **304** continues to move from the intermediate position towards the closed position, the door **304** entrains (or applies a torque to) the tab **315** to pull the guide members **305** with the door **304** back to the closed position. Accordingly, the guide members **305** pivot in unison with the door **304** when the door **304** moves along the path of travel T from the intermediate position to the closed position.

In one embodiment, guide members **305** rotate only between a closed position when tabs **315** engage the inside of wall surface **316** and an open position when guide members **305** engage cables or edge **317** of wall surface **316**. Compare FIG. **24** and FIG. **29**. Door **304** can rotate further due to the second independent hinge which allows additional opening. Compare FIG. **24** and FIG. **27**. Engagement of door flange **304a** and guide member hinge flange **309** limits the amount of opening of door **304**. See FIG. **28**.

FIGS. **32** and **33** illustrate example systems in which the enclosure **300** disclosed above can be utilized. FIG. **32** illustrates a cabinet **400** (e.g., a fiber distribution hub) that is configured to hold one or more enclosures **300**. In the example shown, the cabinet **400** includes a housing **401** and at least one door **402** that covers an opening leading to the interior **403** of the housing **401**. In some implementations, cables (e.g., subscriber distribution cables) enter the housing interior **403** and are routed into the enclosures **300** and to the rear ports **324** of the termination fields **320**. Additional cables (e.g., feeder cables) also enter the housing interior **403** and are routed to the front ports **322** of the termination fields **320** to connect subscribers to the network. The rear ports **324** can be accessed (e.g., for cleaning, for adding/removing/changing connections, etc.) by opening the enclosure door **304**.

Cable management structures **405** (e.g., storage spools, bend radius limiters, retaining fingers, etc.) are disposed within the cabinet interior **403** to guide cables within the cabinet **400**. Some of the cable management structures **405** cooperate with the enclosures **300** to define routing channels C1 along sides of the cabinet interior **403**. Cables can be routed through the channels C1 (e.g., to store slack length) between various components within the cabinet **400**. When the enclosure doors **304** are opened, the guide members **305** of the enclosures **300** may impinge upon the cables within the channels C1. In conventional systems, rigidly attached guide members would limit the opening angle of the enclosure doors when they hit the cables in the channels C1 (or the management structures or the side of the cabinet). Advantageously, the enclosure doors **404** of the above-described enclosure **300** can continue to open after the guide members **305** (i.e., have a larger opening angle) are stopped by these cables.

FIG. **33** illustrates a rack **450** (e.g., an inside-plant frame) that is configured to hold one or more enclosures **300**. In the example shown, the rack **450** includes a frame **451** to which the enclosures **300** can be mounted. Incoming and outgoing cables enter the frame **451**, route around cable management structures **452** (e.g., storage spools, bend radius limiters, retaining fingers, etc.), and connect together at the termination fields **320** of the enclosures **300**. In certain implementations, the incoming and outgoing cables can be routed to rear ports **324** of the termination fields **320** and patch cords can be routed between front ports **322** of the termination fields **320** to connect the incoming and outgoing cables. The

enclosure rear ports **324** can be accessed (e.g., for cleaning, for adding/removing/changing connections, etc.) by opening the enclosure doors **304**.

As shown, some of the cable management structures **452** cooperate with the enclosures **300** to define routing channels **C2** along sides of the cabinet interior **403**. Cables can be routed through the channels **C1** (e.g., to store slack length) between various equipment within the rack **450**. When the enclosure doors **304** are opened, the guide members **305** of the enclosures **300** may impinge upon the cables within the channels **C2** (or the management structures). In conventional systems, rigidly attached guide members would limit the opening angle of the enclosure doors when they hit the cables in the channels **C2**. Advantageously, the enclosure doors **304** of the above-described enclosure **300** can continue to open after the guide members **305** (i.e., have a larger opening angle) are stopped by these cables.

While this invention has been particularly shown and described with references to preferred embodiments thereof, it will be understood by those skilled in the art that various changes in form and details may be made therein without departing from the scope of the invention encompassed by the appended claims. The drawings are not necessarily to scale, emphasis instead being placed upon illustrating the principles of the invention and other modifications within the scope. Any such modifications or variations that fall within the purview of this description are intended to be included therein as well. It is understood that the description herein is intended to be illustrative only and is not intended to be limitative.

What is claimed is:

1. A telecommunications arrangement comprising:
 - a base body defining an interior accessible through an open front that extends between a first side and a second side;
 - a termination field coupled to the base body to pivot relative to the base body along a path of travel between a first position and a second position, the termination field being between the first and second sides of the base body when in the first position, and the termination field providing access to the open front when in the second position; and
 - a guide member coupled to the base body to provide bend radius protection to cables plugged into the termination field, the guide member defining a channel pivotable relative to the base body and pivotable relative to the termination field, wherein the channel leads the cables from the termination field towards the first side of the base body at an exterior of the base body, wherein the guide member is configured to be rotated by the cables.
2. The telecommunications arrangement of claim 1, the termination field is configured to pivot with the guide member relative to the base body as the termination field pivots along a first portion of the path of travel, and the

termination field being configured to pivot relative to the guide member as the termination field pivots along a second portion of the path of travel.

3. The telecommunications arrangement of claim 1, wherein the termination field pivots about a first axis and the guide member pivots about a second axis that is spaced from the first axis.

4. The telecommunications arrangement of claim 1, wherein the termination field and the guide member pivot about a common axis.

5. The telecommunications arrangement of claim 1, wherein the termination field includes a plurality of rows of optical adapters.

6. The telecommunications arrangement of claim 5, wherein the guide member defines a plurality of channels to hold optical fibers.

7. The telecommunications arrangement of claim 1, further comprising:

a second termination field coupled to the base body to pivot relative to the base body along a respective path of travel; and

a second guide member coupled to the base body to pivot relative to the base body and to pivot relative to the termination field, the second guide member defining a respective channel leading additional cables from the second termination field towards the first side of the base body at an exterior of the base body.

8. The telecommunications arrangement of claim 1, wherein the guide member does not extend across any optical adapters of the termination field.

9. The telecommunications arrangement of claim 1, wherein the base body includes an enclosure body and the termination field is carried by a door.

10. The telecommunications arrangement of claim 1, wherein the base body includes a chassis and the termination field is carried by a tray.

11. A telecommunications panel comprising:

a chassis;

a tray rotatably mounted to the chassis by a hinge, the tray moveable in and out of the chassis; and

a guide member rotatably mounted to the chassis, the guide member adapted to provide bend radius protection to cables routed to the telecommunications panel, wherein the guide member compensates for route length reduction of a route of the cables when the tray is moved from an installed configuration to an access configuration; wherein the guide member is configured to be actuated by the cables when the tray is moved between an installed configuration and an access configuration.

12. The telecommunications panel of claim 11, wherein the hinge rotates about a first axis and the guide member rotates about a second axis that is spaced from the first axis.

13. The telecommunications panel of claim 12, wherein the second axis is positioned outside a boundary of the chassis.

14. The telecommunications panel of claim 12, wherein the guide member rotates away from the first axis when the tray is moved from an installed configuration to an access configuration.

15. The telecommunications panel of claim 12, wherein the second axis is positioned outside a boundary of the chassis.

16. The telecommunications panel of claim 12, wherein the guide member rotates away from the first axis when the tray is moved from an installed configuration to an access configuration.

17. The telecommunications panel of claim 11, wherein the guide member adds route length to a route of the cables when the tray is moved from an installed configuration to an access configuration.

18. The telecommunications panel of claim 11, wherein the hinge includes a sleeve of the tray mounted about a pin, wherein the pin is mounted to the chassis, wherein the sleeve is removable from the pin without removing the pin from the chassis, and wherein the tray is removable from the chassis by removing the sleeve from the pin.

19. A method of using a telecommunication panel, comprising:

providing the telecommunication panel including a chassis, a tray, a hinge, and a guide member;

moving the tray between an installed configuration and an access configuration by rotating the hinge;

rotating the guide member while moving the tray, wherein a rotational axis of the hinge is offset from a rotational axis of the guide member; and

providing bend radius protection to cables routed to the telecommunications panel with the rotating guide member, wherein the cables rotate the guide member.

20. The method of claim 19, further comprising adding route length to a route of the cables with the guide member when the tray is moved from the installed configuration to the access configuration.

21. A telecommunications panel comprising:

a chassis;

a tray rotatably mounted to the chassis by a hinge, wherein the hinge rotates about a first axis, the tray moveable in and out of the chassis; and

a guide member defining a channel rotatably mounted to the chassis, the guide member adapted to provide bend radius protection to cables routed to the telecommunications panel, wherein the guide member rotates about a second axis that is spaced from the first axis, wherein the guide member is configured to be rotated by the cables.

22. A telecommunications panel comprising:

a chassis;

a tray rotatably mounted to the chassis by a hinge, the tray moveable in and out of the chassis; and

a guide member defining a channel rotatably mounted to the chassis, the guide member adapted to provide bend radius protection to cables routed to the telecommunications panel, wherein the guide member adds route length to a route of the cables when the tray is moved from an installed configuration to an access configuration, wherein the guide member is configured to be rotated by the cables.
