FIELD OF THE INVENTION

The present invention relates to compounds and pharmaceutical formulations that can be used to treat conditions mediated by nuclear hormone receptors, more specifically, to compounds and pharmaceutical formulations that modulate Peroxisome Proliferator Activation Receptor (PPAR) activity.

BACKGROUND OF THE INVENTION

Hypercholesterolemia, dyslipidemia, diabetes, and obesity are well-recognized risk factors in the onset of atherosclerosis and coronary heart disease. The diseases are characterized by high levels of cholesterol and lipids in the blood. The blood cholesterol pool is generally dependent on dietary uptake of cholesterol from the intestine, and from the biosynthesis of cholesterol throughout the body, especially the liver. The majority of cholesterol in plasma is carried on apolipoprotein B-containing lipoproteins, such as low-density lipoproteins (LDL) and very-low-density lipoproteins (VLDL). The risk of coronary artery disease in man increases when LDL and VLDL levels increase. Conversely, high levels of cholesterol carried in high-density lipoproteins (HDL) is protective against coronary artery disease (Am. J. Med., 1977;62:707-714).

The statins represent perhaps the most important class of lipid-lowering drugs. These compounds inhibit HMG-CoA reductase which is implicated in the rate-limiting step in cellular cholesterol biosynthesis. Representative statins include atorvastatin, lovastatin, pravastatin, and simvastatin. The effectiveness of these compounds depends on LDL receptor regulation. Other important antilipidemia drugs include fibrates such as gemfibрил and clofibrate, bile acid sequestrants such as cholestyramine and colestipol, probucol, and nicotinic acid analogs.

To date, a number of oral antidiabetic agents have been developed. The most commonly used hypoglycemic drugs are the sulfonylureas. Sulfonylureas are generally used to stimulate insulin. The biguanide metformin is generally used to improve insulin sensitivity and to decrease hepatic glucose output. Acarbose is used to limit postprandial hyperglycemia. Thiazolidine 2,4 diones are used to enhance insulin action without increasing insulin secretion.

Obesity is a chronic disease that is highly prevalent in modern society and is associated not only with a social stigma, but also with decreased life span and numerous medical problems, including diabetes mellitus, insulin resistance, hypertension, hypercholesterolemia, thromboembolic disease, and coronary heart disease. Rissanen et al, British Medical Journal, 301:835-837 (1990). Treatment

of obesity remains a problem and it is unclear whether dieting results in decreased long-term risk of early death. A further important obesity intervention is physical activity. Exercise, however, in general, has been found to be only moderately successful in promoting weight loss. A program combining both dieting and exercise as well as behaviour modification is widely viewed as the optimal approach to weight loss. Studies have demonstrated that the combination of both food restriction and exercise promote a substantial loss of fat while maintaining lean tissue.

Peroxisome Proliferator Activation Receptors (PPAR) are implicated in a number of biological processes and disease states including hypercholesterolemia, dyslipidemia, and diabetes. PPARs are members of the nuclear receptor superfamily of transcription factors that includes steroid, thyroid, and vitamin D receptors. They play a role in controlling expression of proteins that regulate lipid metabolism. Furthermore, the PPARs are activated by fatty acids and fatty acid metabolites. There are three PPAR subtypes PPAR α , PPAR β (also referred to as PPAR δ), and PPAR γ . Each receptor shows a different pattern of tissue expression, and differences in activation by structurally diverse compounds. PPAR γ , for instance, is expressed most abundantly in adipose tissue and at lower levels in skeletal muscle, heart, liver, intestine, kidney, vascular endothelial and smooth muscle cells as well as macrophages. PPAR receptors are associated with regulation of insulin sensitivity and blood glucose levels, macrophage differentiation, inflammatory response, and cell differentiation. Accordingly, PPARs have been associated with obesity, diabetes, carcinogenesis, hyperplasia, atherosclerosis, dyslipidemia, and hypercholesterolemia.

In addition, PPAR α agonists lower plasma triglycerides and LDL cholesterol and are therefore useful in treating hypertriglyceridemia, dyslipidemia and obesity. PPAR γ is associated with the development of non-insulin-dependent diabetes mellitus (NIDDM), hypertension, coronary artery disease, dyslipidemia and certain malignancies. Finally, activation of PPAR β has been demonstrated to increase HDL levels. (Leibowitz, WO97/28149, August 1997.) More recently, a PPAR β selective agonist was reported to have shown a dose-related increase in serum HDL-C and decrease in LDL-C and VLDL-TG in insulin-resistant middle aged rhesus monkeys. (W. R. Oliver et al., PNAS, v. 98, pp. 5306-5311, 2001)

Antilipidemic, antidiabetic and anti-obesity agents are still considered to have non-uniform effectiveness. The effectiveness of antidiabetic and antilipidemic therapies is limited, in part because of poor patient compliance due to unacceptable side effects. These side effects include diarrhea and gastrointestinal discomfort, and in the case of antidiabetics, edema, hypoglycemia and hepatotoxicity. Furthermore, each type of drug does not work equally well in all patients.

For the reasons set forth above, there is a need for novel antilipidemic, antidiabetic, and anti-obesity agents that can be used alone or in combination. Furthermore, activation of multiple PPARs, for instance, PPAR β alone or in combination with the simultaneous activation of PPAR α and/or PPAR γ , may be desirable in formulating a treatment for dyslipidemia in which HDL is increased and LDL lowered.

The present invention includes all diastereomeric, enantiomeric, and epimeric forms as well as the appropriate mixtures thereof. Stereoisomers may be obtained, if desired, by methods known in the art as, for example, the separation of stereoisomers by chiral chromatographic columns. Additionally, the compounds of the present invention may exist as geometric isomers. The present invention includes all cis, trans, syn, anti, entgegen (E), and zusammen (Z) isomers as well as the appropriate mixtures thereof

In some situations, compounds may exist as tautomers. All tautomers are included within Formulas I and II and are provided by this invention.

In addition, the compounds of the present invention can exist in unsolvated as well as solvated forms with pharmaceutically acceptable solvents such as water, ethanol, and the like. In general, the solvated forms are considered equivalent to the unsolvated forms for the purposes of the present invention.

The present invention includes all pharmaceutically acceptable, non-toxic esters of the compounds of Formulae I and II. Such esters include C₁-C₆ alkyl esters where the alkyl group is a straight or branched chain. Acceptable esters also include C₅-C₇ cycloalkyl esters as well as arylalkyl esters such as, but not limited to benzyl. C₁-C₄ esters are preferred. Esters of the compounds of the present invention may be prepared according to conventional methods.

The compounds of the present invention are suitable to be administered to a patient for the treatment, control, or prevention of hypercholesteremia, dyslipidemia, obesity, hyperglycemia, hypercholesteremia, atherosclerosis, hypertriglyceridemia, and hyperinsulinemia. The compounds of the present invention are also suitable to be administered to a patient for the suppression of appetite and modulation of leptin. Accordingly, the compounds may be administered to a patient alone or as part of a composition that contains other components such as excipients, diluents, and carriers, all of which are well-known in the art. The compositions can be administered to humans and/or animals either orally, rectally, parenterally (intravenously, intramuscularly, or subcutaneously), intracisternally, intravaginally, intraperitoneally, intravesically, locally (powders, ointments, or drops), or as a buccal or nasal spray.

Compositions suitable for parenteral injection may comprise physiologically acceptable sterile aqueous or nonaque-

Prevention of the action of microorganisms can be ensured by various antibacterial and antifungal agents, for example, parabens, chlorobutanol, phenol, sorbic acid, and the like. It may also be desirable to include isotonic agents, for example sugars, sodium chloride, and the like. Prolonged absorption of the injectable pharmaceutical form can be brought about by the use of agents delaying absorption, for example, aluminum monostearate and gelatin.

Solid dosage forms for oral administration include capsules, tablets, pills, powders, and granules. In such solid dosage forms, the active compound is admixed with at least one inert customary excipient (or carrier) such as sodium citrate or dicalcium phosphate or (a) fillers or extenders, as for example, starches, lactose, sucrose, glucose, mannitol, and silicic acid; (b) binders, as for example, carboxymethylcellulose, alginates, gelatin, polyvinylpyrrolidone, sucrose, and acacia; (c) humectants, as for example, glycerol; (d) disintegrating agents, as for example, agar, calcium carbonate, potato or tapioca starch, alginic acid, certain complex silicates, and sodium carbonate; (e) solution retarders, as for example paraffin; (f) absorption accelerators, as for example, quaternary ammonium compounds; (g) wetting agents, as for example, cetyl alcohol and glycerol monostearate; (h) adsorbents, as for example, kaolin and bentonite; and (i) lubricants, as for example, talc, calcium stearate, magnesium stearate, solid polyethylene glycols, sodium lauryl sulfate, or mixtures thereof. Solid dosage forms such as tablets, dragees, capsules, pills, and granules can be prepared with coatings and shells, such as enteric coatings and others well-known in the art. They may contain opacifying agents, and can also be of such composition that they release the active compound or compounds in a certain part of the intestinal tract in a delayed manner. Examples of embedding compositions which can be used are polymeric substances and waxes. The active compounds can also be in micro-encapsulated form, if appropriate, with one or more of the above-mentioned excipients.

Liquid dosage forms for oral administration include pharmaceutically acceptable emulsions, solutions, suspensions, syrups, and elixirs. In addition to the active compounds, the liquid dosage forms may contain inert diluents commonly used in the art, such as water or other solvents, solubilizing agents and emulsifiers, as for example, ethyl alcohol, isopropyl alcohol, ethyl carbonate, ethyl acetate, benzyl alcohol, benzyl benzoate, propyleneglycol, 1,3-butylene glycol, dimethylformamide, oils, in particular, cottonseed oil, groundnut oil, corn germ oil, olive oil, castor oil

25

and sesame oil, glycerol, tetrahydrofurfuryl alcohol, polyethyleneglycols and fatty acid esters of sorbitan or mixtures of these substances, and the like.

Dosage forms for topical administration of a compound of this invention include ointments, powders, sprays, and inhalants. The active component is admixed under sterile conditions with a physiologically acceptable carrier and any preservatives, buffers, or propellants as may be required. Ophthalmic formulations, eye ointments, powders, and solutions are also contemplated as being within the scope of this invention.

The compounds of the present invention can be administered to a patient at dosage levels in the range of about 0.1 to about 2,000 mg per day. For a normal human adult having a body weight of about 70 kilograms, a dosage in the range of about 0.01 to about 10 mg per kilogram of body weight per day is preferable. However, the specific dosage used can vary. For example, the dosage can depend on a number of factors including the requirements of the patient, the severity of the condition being treated, and the pharmacological activity of the compound being used. Many of the compounds with Formulas I and II are preferably made by reacting:

in a solvent in the presence of a base such as cesium carbonate, with the aryl halide:

wherein:

n , R^1 , R^2 , R^3 , R^4 , X^0 , X^1 , V^1 , Ar^1 , and Ar^2 are the same as defined above for Formula I;

R^{11} is a lower alkyl; and

X is a halogen.

The resulting ester is then preferably hydrolyzed to form the compounds of Formulas I and II. Specifically, compounds of Formulas I and II can be prepared using the synthetic route outlined in Scheme 1-6.

Scheme 1 covers the preparation of compounds of Formulas I and II wherein X^0 is S, q is 0-3,

is absent, X^1 is absent and r is 0. Compounds of the general formula A are thiocyanated with a mixture of bromine and sodium thiocyanate to give compounds of the general formula B. Compounds of the general formula B are then alkylated with an alkyl haloacetate to give compounds of the general formula C. The preferred alkyl haloacetate is methyl bromoacetate. Alternate routes to compounds of formula C will be readily apparent to a person skilled in the art of organic synthesis. Compounds of the general formula D are then prepared by reduction of C with dithiothreitol in methanol. Compounds of the general formula D are then alkylated with compounds of the general formula Y in the same manner as for B to give E. Compounds of the general formula Y are prepared as described in Scheme 7 (below) or are readily available from commercial sources. Compounds of the general formula E are then, saponified with LiOH in the THF to give the final compound F.

is absent, and r is 0. Compounds of the general formula A are alkylated with an alkyl haloacetate to give compounds of the general formula G. The preferred alkyl haloacetate is methyl bromoacetate. Alternate routes to compounds of formula G when Y is O will be readily apparent to a person skilled in the art of organic synthesis. Compounds of the general formula G are then acylated using Friedel-Crafts conditions to give compounds of the general formula H

Alternatively, N-bromosuccinimide may be used in place of bromine and dichloromethane in place of acetic acid as solvent. Compounds of the general formula L are then alkylated with an alkyl haloacrylate to give compounds of the general formula M. The preferred alkyl haloacrylate is methyl bromoacetate. Alternate routes to compounds of formula M will be readily apparent to a person skilled in the art of organic synthesis. Compounds of the general formula M are then reacted in the presence of tetrakis (triphenylphosphine)palladium(0) and biphenyl compounds of the general formula EE to give compounds of the general formula N. Compounds of the general formula EE are prepared as described in Scheme 9 or are readily available from commercial sources. Compounds of the general formula N are then saponified with LiOH in THF to give the final compound O.

With reference to Scheme 6, compounds of formula I-II wherein X⁰ is S or O, q is 1-3, X¹ is O, and r is 1-3 are

32

prepared using the same conditions utilized for the preparation of K.

With reference to Scheme 7, compounds of the general formula X are prepared by reacting aryl boronic acid W with aryl bromide V in the presence of Pd(0) and cesium carbonate. Compounds of the general formula X are then reacted with methanesulfonyl chloride to give chlorides of the general formula Y.

With reference to Scheme 8, compounds of the general formula CC are prepared wherein an appropriate hydroxy benzyl alcohol AA is alkylated with an appropriate bromide Z. The resulting compound BB is then reacted with methanesulfonyl chloride to give chlorides of the general formula CC.

33

With reference to Scheme 9, compounds of the general formula EE are prepared by reacting aryl boronic acid V with aryl bromide DD in the presence of Pd(0) and cesium carbonate.

With reference to Scheme 10, compounds of the general formula HH are prepared by reacting aryl bromide V with boronic acid FF to give GG. Compounds of the general formula GG are then reacted with an alkyl lithium reagent and then quenched with a borate which is hydrolyzed to give compounds of the general formula HH.

With reference to Scheme 11, compounds of formula I-II wherein X⁰ is S or O, q is 1-3, X¹ is absent, r is O, and V¹ is a saturated or unsaturated hydrocarbon chain which is substituted or unsubstituted are prepared using the same

34

conditions utilized for the preparation of K. Compounds of the general formula NN are prepared as described in Scheme 12 or are readily available from commercial sources.

With reference to Scheme 12, compounds of the general formula NN can be prepared by reacting an appropriately substituted aryl amine LL under Sandmeyer conditions followed by heating to give intermediate MM. The resulting intermediate MM is then reacted with methanesulfonyl chloride to give chlorides of the general formula NN.

Alcohol Preparation:

The appropriate alcohols in the salt form (0.65 mmol) were dissolved in 3.0 mL of low water MeOH. MP-CO₃ (3.21 mmol/g, 3.70 equivalents to alcohol, 2.41 mmol) was then added to each vial containing the alcohol and shaken at ambient temperature for 3 h. The samples were then filtered into tared vials and concentrated.

PS-morpholine (4.0 mmol/g, 2 equivalents to alcohol, 0.3 mmol) and 25 μL methanesulfonyl chloride was then added to each reaction tube. The reaction tubes were shaken at ambient temperature for 16 h. The samples were then filtered into collection tubes, the resin rinsed with two 1.0 mL aliquots of DCM, and concentrated.

A. Selectivity Measurements

1. Test A. Transient Transfections Assay using the HepG2Hepatoma Cell Line.

HepG2 cells were transiently transfected with an expression plasmids encoding hPPAR α , hPPAR β or mPPAR γ chimeric receptors and a reporter containing the yeast upstream activating sequence (UAS) upstream of the viral E1B promoter controlling a luciferase reporter gene. In addition, the plasmid pRSV β -gal was used to control the transfection efficiency, HepG2 cells were grown in DMEM supplemented with 10% FBS and 1 μ M non-essential amino acid. On the first day, cells were split into 100 mm dishes at 2.5×10^8 /dish and incubated overnight at 37° C./5% CO₂. On the second day the cells were transiently transfected with plasmid DNA encoding a chimeric receptor, the luciferase reporter gene; and β -gal. For each 100 mm dish, 15 μ g of luciferase reporter (PG5E1b) DNA, 15 μ g of Gal4-PPAR chimeric receptor DNA, and 1.5 μ g of β -gal plasmid DNA were mixed with 1.4 ml of opti-MEM in the tube. 28 μ l of LipoFectamine-2000 reagent was added to 1.4 ml of opti-MEM in the tube, and incubate for 5 min at RT. The diluted LipoFectamine-2000 reagent was combined with the DNA mixture, and incubate for 20 min at RT. After fresh medium was added to each 100 mm dish of cells, 2.8 ml of Lipofectamine2000-DNA mixture was added dropwise to the 100 mm dish containing 14 ml of medium, and incubate 37° C. overnight. On day three cells were trypsinized off the 100 mm dishes and re-plated on 96 well plates. Cells were plated at 2.5×10^4 cells per well in 150 μ l of media and 50 μ l of compound diluted by media was added. The test compound added were in the range from 50 μ M to 50 pM. After addition of compounds, the plates were incubated at 37° C. for 24 hours. Subsequently cells were washed with once with 100 μ l of PBS, lysed, and processed for measuring luciferase and β -gal activity using Dual-Light luciferase kit from Tropix®, according to the manufacturer's recommendations, on an EG&G Bethold MicroLumat LB96P luminometer. EC₅₀ values were obtained using the GraphPad Prism™ program. Surprisingly, the compounds of the present invention exhibit activity for both PPAR α and PPAR β . Compounds of the present invention exhibited a range of Hep G2-hBeta EC₅₀'s ("EC₅₀ β ") and Hep G2-hAlpha EC₅₀'s ("EC₅₀ α ") from greater than zero to about 20 μ M. Specifically, as shown in Table 1, the Hep G2-hBeta EC₅₀'s and Hep G2-hAlpha EC₅₀'s for the com

B. Effect of PPAR Modulators on Lipid and Human Apo-protein A1 Concentrations in the hApoA1 Transgenic Mouse

Mice, transgenic for human apoA1, were purchased from Jackson laboratories. All animals were allowed normal chow (Ralston-Purina) and water ad libitum in temperature controlled rooms, under a 12-h light, 12-h dark cycle beginning with lights on at 6 AM. During the treatment phase of the study the mice were dosed daily between 6 and 9 AM by oral gavage using a suspension vehicle of 1.5% carboxymethyl-cellulose plus 0.2 percent Tween-20 (CMC/Tween) containing the specific compounds. Control animals received vehicle alone. Vehicle volume represented 0.25 percent of body weight. Under anesthesia, tail blood was obtained weekly in the morning at the indicated days of study. At termination, tissue samples (liver, intestine, fat, and muscle) were taken to study effects on genes effecting lipid metabolism. Each of the compounds of the present invention that were tested effected a significant increase in HDL over the values observed for the control animals. Furthermore, these compounds resulted in triglyceride levels which were lower than observed in controls. Compounds of the present invention tested in the hApoAI transgenic mouse model showed a range of HDL-c elevation and triglyceride lowering when dosed at 30 mg/kg/day. For instance, Example 4 raised HDL-c 97% and lowered triglycerides 65 % relative to the control population, Example 6 raised HDL-c 24% and lowered triglycerides 59 % relative to the control population, and Example 3 raised HDL-c 9% and lowered triglycerides 70% relative to the control population.

5 C. Effect of Compounds of the Invention on Insulin Resistant or Diabetic Cynomolgus Monkeys

Cynomolgus monkeys that were either insulin resistant or diabetic (type II) were treated for eight weeks with [5-Methoxy-2-methyl-4-(4'-trifluoromethyl-biphenyl-4-ylmethylsulfanyl)-phenoxy]-acetic acid in a rising dose fashion (0.1 to 1 mg/kg). Plasma was sampled bi-weekly and analyzed for glycemics and leptin. Body weight was also measured at various time points across the study. The diabetic monkey mean body weight data is presented in Table 2 and the insulin resistant monkey mean body weight data is presented in Table 3.

35 Plasma leptin values, presented as baseline values vs. 8-week treatment, were determined by ELISA and are presented in Table 4. The effect of [5-Methoxy-2-methyl-4-(4'-trifluoromethyl-biphenyl-4-ylmethylsulfanyl)-phenoxy]-acetic acid on plasma leptin values in diabetic and insulin resistant obese cynomolgus monkeys is demonstrated by the lesser increase in plasma leptin values seen in the treated animals.

45 The amount of exogenous insulin the diabetic monkeys received to maintain proper glucose levels, the exogenous insulin requirement, is also presented in Table 4 as baseline values vs. 8-week treatment. By definition, insulin resistant monkeys are not yet diabetic and do not receive exogenous insulin. A reduction in exogenous insulin requirements is a measure of improved insulin sensitivity and glucose control.
