U.S. Applications:

(63) Continuation of application No. 10/848,616, filed on May 19, 2004, now abandoned, which is a division of application No. 08/735,572, filed on Oct. 23, 1996, now Pat. No. 6,535,467, which is a continuation of application No. 08/307,288, filed on Sep. 16, 1994, now abandoned.

[This invention relates to a karaoke CD format and a device for controlling audio signals utilizing the karaoke CD format which provides a user with selective reproduction of the voice of a player. The karaoke CD format includes a CD format divided into video sectors and audio sectors. The audio sectors are further divided into a part for recording accompaniment sound and playing sound at the same time and a part for recording accompaniment sound only. There is provided record coding information for distinguishing the parts.] *A device, method and recording medium for reproducing digital data, are discussed. According to an embodiment, the recording medium includes digital audio data recorded thereon, the digital audio data comprising data units corresponding to at least one of: a first type of digital audio data, and a second type of digital audio data which includes at least one content different from the first type of digital audio data. Each data unit includes supplementary information, which has: a) coding information indicating a coding mode of the digital audio data, b) identification information, different than the coding information, identifying the data unit as one of the first type of digital audio data or the second type of digital audio, and c) time information controlling a presentation timing of data units of the first or second type.*

No. 08/307,288 filed Sep. 16, 1994 (now abandoned). The present application also claims foreign priority benefits of Korean Patent Application No. 93-18841 filed Sep. 17, 1993 in The Republic of Korea. The entirety of each of the above-identified documents is hereby incorporated by reference. Note: More than one reissue application has been filed for the reissue of U.S. Pat. No. 6,721,249. The reissue applications are application Ser. No. 10/848,616 (parent of the present application); Ser. No. 11/058,630 (the present application); Ser. No. 10/848,617 (now abandoned); Ser. Nos. 11/905,506; 12/142,642; 12/142,658; 12/142,663; 12/142,674; 12/142,680; and 12/142,684 which are continuations of the present application.

BACKGROUND OF THE INVENTION

1. Field of the Invention

This invention relates to a karaoke CD system, more particularly to a karaoke CD format and a device for processing audio signals utilizing the karaoke CD format which provides a user with selective reproduction of the voice of a player.

2. Description of Related Art

As shown in FIG. 1, a general disc data layout of a karaoke CD includes lead in/lead out areas **1** and **6** formed at the lead in and lead out of the CD for encoding CD-ROMXA data containing empty sectors of mode **2**/form **2** therein, and program areas **2**, **3**, **4**, and **5**.

The program areas include a volume descriptor area **2** formed next to the lead in area **1** containing the path name of a CDI application program described in compact disc bridge system description. The basic data area **3** is for recording the title of a song, the name of the singer, the composer of the song, and the songwriter. The CDI application program area **4** is for recording an application program required for converting into compact disc bridge system description which will facilitate the operation of a disc in CD-RTOS (Real Time Operating System) in a CD-I/FMV player. The MPEG data area **5** is for recording MPEG (Moving Picture Experts Group) video and audio data.

The lead in area **1** has records of the number of songs, the period of time of each song and total period of time, and the lead in part and index part of each song. The lead out area **6** has record of the end of the program.

As shown in FIG. 2, a conventional karaoke CD system includes a first demodulation part **11** for demodulating EFM (Eight to Fourteen Modulation) signals. A second modulation part **12** for demodulating signals recorded in interleaved sectors for a CD-ROM upon receiving signals from the first demodulation part **11**. A CPU **16** for demultiplexing system flow on receiving signals from the second demodulation part **12**. A first, and a second memory **17** and **18** for storing video and audio data received from the CPU **16** respectively. A MPEG video decoder **19** and a MPEG audio decoder **20** for decoding MPEG video signals and MPEG audio signals of the video and audio data stored in the first and the second memories **17** and **18** respectively. A STC (System Time Clock) **23** for clocking the system time under the control of the CPU **16**. A video and audio signal processing part **13** having a video presentation part **21** for comparing the STC of the STC part **23** to PTS (Presentation Time Stamps) in the bit stream received from the MPEG video decoder **19**. An audio presentation part **22** for comparing the STC of the STC part **23** to PTS (Presentation Tune Stamps) in the bit stream received from the MPEG audio decoder **20**. A control part **10** for controlling both the first and the second demodulation parts **11** and **12** and for controlling the video and audio signal processing part **13** according to a key signal applied thereto. A Digital-to-Analog (D/A) converter **14** for converting the video signal received from the video presentation part **21** and outputting the converted signal to a monitor under the control of the control part **10**, and a D/A converter **15** for converting the audio signal received from the audio presentation part **22** and applying the converted signal to a speaker under the control of the control part **10**.

The interleaving of a conventional MPEG video and MPEG audio sectors is as shown in FIG. 3.

Since the quantity of MPEG video data is much greater than the quantity of MPEG audio data, an MPEG audio sector A is periodically positioned in between MPEG video sectors V. For example, one MPEG audio sector A may be present in every four MPEG video sectors V.

Shown in Table 1 is the audio channel encoding, which is to be explained in detail hereinafter.

TABLE 1

	Stereo Music Program	Special Music Program
CH 0	Left	mono without vocal
CH 1	Right	mono with vocal

The karaoke CD format includes a stereo music program having a left audio channel for encoding on MPEG audio channel 0 and a right audio channel for encoding on MPEG audio channel 1, and a special music program having one channel for encoding music accompaniment sound without vocal and the other channel for encoding music accompaniment sound with vocal.

Operation of the conventional karaoke CD system is to be explained hereinafter.

The karaoke data is read in through a pick-up, having EFM demodulated and CD errors corrected through the first demodulation part **11** which is an EFM/CIRC (Cross Interleave Read Solomon Code) decoder. The data interleaved at encoding is demodulated through the second demodulation part **12** which is a CD-ROM decoder. The data is divided into audio data and video data through the video and audio signal processing part **13** under the demultiplexing operation of the CPU **16** and applied to the MPEG video decoder **19** and MPEG audio decoder **20** through the first and the second memories **17** and **18** respectively.

3

The MPEG video decoder **19** and the MPEG audio decoder **20**, restore the compressed data, and compare the STC from the STC part **23** to the PTS in the restored data to control the presentation time of the data.

However, such a conventional karaoke-CD system has the disadvantage of being unable to obtain stereophony sound in the case where music without vocal and music with vocal of a specific music program is carried on the first channel (Left) and the second channel (Right).

SUMMARY OF THE INVENTION

The object of this invention is to provide a user with selective reproduction of playing sound, i.e., voice (song of a singer) and accompaniment sound.

These and other objects and features of this invention can be achieved by providing a karaoke CD format which is divided into video sectors and audio sectors, and the audio sectors are further divided into a part for recording accompaniment sound and vocal sound at the same time and another part for recording accompaniment sound only. The audio sectors are further provided to record coding information for distinguishing between the audio data stored in the two parts. There is provided a device for controlling audio signals using a karaoke CD format including a control means for controlling the entire system according to signals applied from outside the system. There is provided a demodulation means for demodulating a signal read in from a CO which distinguishes between a part containing recorded accompaniment sound and vocal sound at the same time, and another part containing recorded accompaniment sound only under the control of the control means. There is provided an audio signal processing means for processing audio signals using signals received from the demodulation means and transmitting data corresponding to a first data signal corresponding to the accompaniment sound and playing sound and a second data signal corresponding to the playing sound only, a switching means for selecting one of the first or second data signals and outputting the selected data under the control of the control means, and a D/A converting means for converting the data received from the switching means and applying the converted data to a speaker under the control of the control means.

According to one embodiment, the present invention is directed to a device for reproducing a digital data recorded on a medium, the digital data including a video data and an audio data, the audio data being composed of data units, the data units corresponding to at least one of: 1) a first type of digital audio data, and 2) a second type of digital audio data which includes at least one content different from the first type of digital audio data; each data unit including attribute information, which has: a) first information indicating a coding mode of the digital audio data, and b) second information, different than the first information, identifying the data unit as one of the first type of digital audio data or the second type of digital audio data; the data units of digital audio data being interleaved between data units of digital video data, the device comprising: a demodulator configured to demodulate the digital audio data to restore an original signal; a signal processor configured to receive the digital audio data, demodulated by the demodulator, extract the second information, and separate the data units corresponding to the first type of digital audio data from data units corresponding to the second type of digital audio data based on the extracted second information, the signal processor including a system time clock, a memory configured to store the data units corresponding to the first and second types of

4

digital audio data, and an audio presentation part configured to receive the system time clock to control a presentation timing of the first or second types of digital audio data; and a controller, coupled to the signal processor, configured to control the signal processor to output the data units corresponding to the first or second types of the digital audio data designated by a user input, wherein the first or second types of digital audio data, designated by the user input, is identified using the second information.

According to one embodiment, the present invention is directed to a method for reproducing a digital data recorded on a medium, the digital data including a video data and an audio data, the audio data being composed of data units, the data units corresponding to at least one of: 1) a first type of digital audio data, and 2) a second type of digital audio data which includes at least one content different from the first type of digital audio data; each data unit including attribute information, which has: a) first information indicating a coding mode of the digital audio data, and b) second information, different than the first information, identifying the data unit as one of the first type of digital audio data or the second type of digital audio data; the data units of digital audio data being interleaved between data units of digital video data, the method comprising: demodulating the digital audio data to restore an original signal; receiving the demodulated audio data; extracting the second information; separating the data units corresponding to the first type of digital audio data from the data units corresponding to the second type of digital audio based on the extracted second information, by storing the first and second types of digital audio data in a memory, receiving the data units corresponding to the separated first or second types of digital audio data in an audio presentation part along with a system time clock to control a presentation timing of the first or second types of digital audio data; and outputting one of the first or second types of audio data in response to a user input designating one of the first or second types of audio data, wherein the first or second type of digital audio data, designated by the user input, is identified using the second information.

According to one embodiment, the present invention is directed to a device for processing a digital data, comprising: an audio data processor configured to receive data units of digital audio data, the data units corresponding to at least one of: 1) a first type of digital audio data, and 2) a second type of digital audio data which includes at least one content different from the first type of digital audio data: each data unit [including] being specified by attribute information, which has: a) coding information indicating a coding mode of the digital audio data, and b) identification information, different than the coding information, identifying the data unit as one of the first type of digital audio data or the second type of digital audio data; the audio data processor configured to extract the identification information, and separate the data units of the first type from the data units of the second type using the identification information, the audio data processor including a system time clock, a memory configured to store the data units of the first type and the second type, and an audio presentation part configured to receive the system time clock to control a presentation timing of the data units of the first type or the second type; and a control circuit configured to control the audio data processor to output audio data corresponding to the data units of one of the first or second types, based on the identification information.

According to one embodiment, the present invention is directed to a method for processing a digital data, compris-

ing: receiving data units of digital audio data, the data units corresponding to at least one of: 1) a first type of digital audio data, and 2) a second type of digital audio data which includes at least one content different from the first type of digital audio data; each data unit [including] being specified by attribute information, which has: a) coding information indicating a coding mode of the digital audio data, and b) identification information, different than the coding information, identifying the data unit as one of the first type of digital audio data or the second type of digital audio data; extracting the identification information; separating the data units of the first type from the data units of the second type using the identification information by storing the data units of the first and second types in a memory, receiving the data units of the first or second types in an audio presentation part along with a system time clock to control a presentation timing of data units of the first or second type; and outputting audio data corresponding to the data units of the first or second type in response to the identification information.

According to one embodiment, the present invention is directed to a recording medium on which digital audio data is recorded, the digital audio data comprising of data units corresponding to at least one of: a first type of digital audio data, and a second type of digital audio data which includes at least one content different from the first type of digital audio data; each data unit including supplementary information, which has: a) coding information indicating a coding mode of the digital audio data, b) identification information, different than the coding information, identifying the data unit as one of the first type of digital audio data or the second type of digital audio data wherein the identification information being used for separating the data units of the first type from the data units of the second type stored in a memory and selectively outputting audio data corresponding to the data units of the first or second type, and c) time information controlling a presentation timing of data units of the first or second type.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a layout of a karaoke CD data.

FIG. 2 is a block diagram of a conventional karaoke CD system.

FIG. 3 is a diagram showing a conventional interleaving of MPEG audio/video sectors.

FIG. 4 is a diagram of a subheader in accordance with this invention.

FIG. 5 is a diagram showing an interleaving of MPEG audio/video sectors in accordance with this invention.

FIG. 6 is a schematic block diagram of a device for controlling karaoke CD audio signal in accordance with this invention.

FIG. 7 is an operational flow diagram of a device for controlling karaoke CD audio signals.

FIG. 8 is an MPEG audio format in accordance with this invention.

DETAILED DESCRIPTION OF THE INVENTION

This invention is to be explained in detail hereinafter, referring to the attached drawings.

A subheader in accordance with this invention is shown in FIG. 4. To distinguish audio data Aa, containing both vocal sound and accompaniment sound, and audio data Ab, containing only accompaniment data, there is provided subheader information in an audio packet, the subheader

includes coding information encoded therein with a distinguishing value applied thereto.

The coding information is, included into a subheader of each sector at data encoding as a distinguishing value, standardized as \$0 F in case of MPEG video, and \$7 F in case of MPEG audio, wherein new coding information (for example 3F) is added to use for a distinguishing signal for the audio data sector Aa, having both vocal sound and accompaniment sound, and the audio data sector Ab having only accompaniment sound.

Interleaving of MPEG video and MPEG audio sectors is as shown in FIG. 5. The interleaving of video data and audio data sectors, in general has 4 to 5 consecutive video sectors V with one audio sector A added thereto, where coding information is used to distinguish a sector containing the encoded Aa and Ab.

Since the increase of buffer size due to the newly added audio sectors Aa and Ab is infinitesimal compared to the image data, it can be ignored.

That is, the karaoke CD format in accordance with this invention includes a CD format divided into video sectors and audio sectors, and the audio sectors are further divided into a part Aa for recording both accompaniment sound and vocal sound at the same time and a part Ab for recording accompaniment sound only, and the audio sectors are further provided to record coding information for distinguishing between audio data stored in the two parts.

As shown in FIG. 6, a device for controlling a karaoke CD audio signal in accordance with this invention in a state having the audio data interleaved as explained above, includes a control part 30, a demodulation part 40, an audio signal processing part 70, a switch 50, and a D/A converting part 60.

The control part 30 controls the entire system according to the signal applied through a key matrix 80.

The demodulation part 40 includes a first demodulator 41 for carrying out EFM demodulation from the CD format provided to distinguish a part Aa for recording accompaniment sound and vocal sound at the same time, and a part Ab for recording accompaniment sound only, where the part is under the control of the control part 30, and a second demodulator 42 for demodulating signals recorded in interleaved sectors for a CD-ROM from the signal received from the first demodulator 41 and applying the second demodulated signal to the audio processing part 70 under the control of the control part 30, thereby demodulating the signal read in from the CD format provided to distinguish a part Aa, for recording accompaniment sound and vocal sound at the same time, and a part Ab, for recording accompaniment sound only, under the control of the control part 30.

The audio signal processing part 70 includes a CPU 71 for separating audio data and time data from the signal received from the second demodulator 42 under the control of the control part 30, a STC (System Time Clock) part 77 for generating a synchronizing signal using time information received from the CPU 71, a memory 72 for storing the audio data received from the CPU 71, an MPEG audio decoder 73 for decoding the MPEG audio data stored in the memory 72, a demultiplexer 74 for separating data received from the MPEG audio decoder 73 into data corresponding to accompaniment sound and vocal sound and data corresponding to accompaniment sound and outputting the separated data under the control of the CPU 71, a first audio presentation part 75 for comparing the PTS (Presentation Time Stamp) in the data corresponding to the accompaniment sound received from the demultiplexer 74 to the signal received from the STC 77 to control presentation time of the

data, and a second audio presentation part 76 for comparing the PTS (Presentation Time Stamp) in the data corresponding to accompaniment sound and vocal sound received from the demultiplexer 74 to the signal received from the STC 77 to control presentation time of the data, thereby processing the audio signal using signals received from the demodulation part 40 to separate the data into data corresponding to a first data containing accompaniment sound only, and outputting the separate data.

The switch 50 selects one of the data corresponding to the accompaniment sound and vocal sound, or to only the accompaniment sound received from the first and the second audio presentation parts 75 and 76 of the audio signal processing part 70 and transmits the selected data under the control of the control part 30.

The D/A converter 60 converts the data received from the switch 50 under the control of the control part 30.

The system and operation for processing a video signal is the same as for a conventional karaoke CD system.

Operation of the device for controlling a karaoke CD audio signal in accordance with this invention as described above is to be explained hereinafter.

The encoded karaoke-CD data having coding information applied thereto is added with a distinguishing value and has EFM signals demodulated through the first demodulation part 41 which is a EFM/CIRC (Cross Interleave Read Solomon Code) and errors of the CD are corrected. The interleaved data at encoding is demodulated through the second demodulation part 42 which is a CD-ROM decoder, and is separated into audio, video, and time data in the CPU 71.

In the instant, of audio data, the demultiplexing signal coming in at the reading in of the coding information is applied to the demultiplexer 74 for operation of the demultiplexer 74.

Of the data demultiplexed in the CPU 71, the MPEG audio data is stored in the memory 72 temporarily, has the compression restored through the MPEG audio decoder 73, and is transmitted. The demodulated audio data received from the MPEG audio decoder 73 is separated into audio data carrying accompaniment sound only and audio data carrying accompaniment sound and vocal sound through the demultiplexer 74, and applied to the first audio data presentation part 75 and the second audio presentation part 76 respectively under the control of the CPU 71.

The audio demultiplexing signal received from the CPU 71 controls the first audio presentation part 75 to compare the received audio data Ab, carrying accompaniment sound only out of the audio signal applied thereto, to a PTS to control the presentation time and controls the second audio presentation part 76 to compare the received audio data Aa, carrying voice, i.e., vocal sound and accompaniment sound out of the audio signal applied thereto to a PTS to control the presentation time. The audio data received from the first and the second audio presentation parts 75 and 76 is applied to the D/A converter 60 through a switching operation of the switch 50 under the control of the control part 30, where it is converted in the D/A converter 60 and output to a speaker.

In this instant, the switch 50 is operated under the control of the control part 30 which is operated according to the key signal applied through the key matrix 80.

Operation of a karaoke CD audio system is to be explained hereinafter, referring to FIG. 7.

First, a subheader and packet header are read 100, and demultiplexing is carried out to separate into an audio demultiplexing signal and a MPEG audio signal 101. The

separated MPEG audio signal is decoded to separate into audio signals containing accompaniment sound only, and audio signals containing both vocal sound and accompaniment sound using the audio demultiplexing signal 102, and the PTS of each packet is read to synchronize and transmit signals 103.

The MPEG audio format, as shown in FIG. 8, generates separated MPEG audio signals Aa and Ab, and audio demultiplexing signals by extracting coding information from the subheaders of each sector, and by reading the packet header and comparing it to the STC, thereby the presentation time of the data can be controlled.

As has been explained, this invention for a karaoke CD system increases the enjoyment of karaoke by reproducing audio data containing a player's voice, i.e., vocal sound and accompaniment sound, and audio data containing accompaniment sound selectively, which permits stereophony sound corresponding to the CD sound.

Although the invention has been described in conjunction with specific embodiments, it is evident that many alternatives and variations will be apparent to those skilled in the art in light of the foregoing description. Accordingly, the invention is intended to embrace all of the alternatives and variations that fall within the spirit and scope of the appended claims.

What is claimed is:

1. A device for reproducing a digital [signal] data recorded on a medium, the digital [signal] data including a video [signal] data and an audio [signal] data, the audio [signal] data being composed of data units, the data units corresponding to at least one of:

- 1) a first type of digital audio data, and
- 2) a second type of digital audio data which includes at least one content different from the first type of digital audio data;

each data unit including attribute information, which has:

- a) first information indicating a coding mode of the digital audio data, and
- b) second information, different than said first information, identifying the data unit as one of the first type of digital audio data or the second type of digital audio data;

the data units of *digital* audio [signal] data being interleaved between data units of *digital* video [signal] data, the device comprising:

a demodulator [for demodulating] configured to demodulate the digital [signal] audio data to restore an original signal;

a signal processor [for receiving] configured to receive the *digital* audio [signal] data, demodulated by the demodulator, [extracting] extract the second information, [separating] and separate the data units corresponding to [a] the first type of *digital* audio [signal] data from data units corresponding to [a] the second type of *digital* audio [signal] data based on the extracted second information, said signal processor including a system time clock, a memory [for storing] configured to store the data units corresponding to the first [type] and [the] second [type] types of *digital* audio [signal] data, and [first or second] an audio presentation [parts receiving] part configured to receive the system time clock to control a presentation timing of the first [type] or [the] second [type] types of *digital* audio [signal] data; and

a controller, coupled to the signal processor, [controlling] configured to control the signal processor

9

to output the data units corresponding to the first [type] or [the] second [type] types of the digital audio [signal] data designated by a user input, wherein the first or second [type] types of digital audio [signal] data, designated by the user input, is identified using the second information.

2. A device as claimed in claim 1, wherein the first type of digital audio [signal] data corresponds to accompaniment sound.

3. A device as claimed in claim 1, wherein the audio signal is encoded by an MPEG coding mode, wherein the signal processor further comprises:

an MPEG audio decoder [for decoding] configured to decode the audio [signal] data.

4. A method for reproducing a digital [signal] data recorded on a medium, said digital [signal] data including a video [signal] data and an audio [signal] data, the audio [signal] data being composed of data units, the data units corresponding to at least one of:

- 1) a first type of digital audio data, and
- 2) a second type of digital audio data which includes at least one content different from the first type of digital audio data;

each data unit including attribute information, which has:

- a) first information indicating a coding mode of the digital audio data, and
- b) second information, different than said first information, identifying the data unit as one of the first type of digital audio data or the second type of digital audio data;

the data units of digital audio [signal] data being interleaved between data units of digital video [signal] data, the method comprising [the steps of]:

demodulating the digital [signal] audio data to restore an original signal;

receiving the demodulated audio [signal] data;

extracting the second information;

separating the data units corresponding to [a] the first type of digital audio [signal] data from the data units corresponding to [a] the second type of digital audio [signal] based on the extracted second information, by storing the first and second types of digital audio [signals] data in a memory, receiving the data units corresponding to the first [and] or second types of digital audio [signals] data in [first and second] an audio presentation [parts] part along with a system time clock to control a presentation timing of the first or second [type] types of digital audio [signal] data; and

outputting one of the first or second types of audio [signals] data in response to a user input designating one of the first or second types of audio [signals] data, wherein the first or second type of digital audio [signal] data, designated by the user input, is identified using the second information.

5. The method of claim 4, wherein the step of separating includes separating the first type of the digital audio [signal] data representing accompaniment sound.

6. A device for processing a digital [signal] data, comprising:

an audio [signal] data processor [receiving] configured to receive data units of digital audio data, the data units corresponding to at least one of:

- 1) a first type of digital audio data, and
- 2) a second type of digital audio data which includes at least one content different from the first type of digital audio data;

10

each data unit [including] being specified by attribute information, which has:

- a) coding information indicating a coding mode of the digital audio data, and
- b) identification information, different than said coding information, identifying the data unit as one of the first type of digital audio data or the second type of digital audio data;

the audio [signal] data processor [extracting] configured to extract the identification information, and [separating] separate the data units of the first type from the data units of the second type using the identification information, said [signal] audio data processor including a system time clock, a memory [for storing] configured to store the data units of the first type and the second type, and [first and second] an audio presentation [parts receiving] part configured to receive the system time clock to control a presentation timing of the data units of the first type or the second type; and a control circuit [controlling] configured to control the audio [signal] data processor to output [an] audio [signal] data corresponding to the data units of one of the first or second types, based on the identification information.

7. The device of claim 6, wherein the audio data of the first type includes accompaniment sound.

8. The device of claim 6, wherein the data units of digital audio data are interleaved with digital video data, and wherein the audio data of the first type includes accompaniment sound and vocals, which are associated with the digital video data.

9. The device of claim 6, wherein the audio [signal] data processor [compares] is configured to compare the system time clock to timing information in the digital audio data, and [outputs] output audio data with a timing based on the comparison.

10. The device of claim 6, wherein the audio [signal] data processor [MPEG decodes] is configured to decode the audio data encoded in MPEG format.

11. The device of claim 6, further comprising:

a demodulator [demodulating] configured to demodulate the digital audio data prior to receipt by the audio [signal] data processor.

12. A method for processing a digital [signal] data, comprising:

receiving data units of digital audio data, the data units corresponding to at least one of:

- 1) a first type of digital audio data, and
- 2) a second type of digital audio data which includes at least one content different from the first type of digital audio data;

each data unit [including] being specified by attribute information, which has:

- a) coding information indicating a coding mode of the digital audio data, and
- b) identification information, different than said coding information, identifying the data unit as one of the first type of digital audio data or the second type of digital audio data;

extracting the identification information;

separating the data units of the first type from the data units of the second type using the identification information by storing the data units of the first and second types in a memory, receiving the data units of the first [and] or second types in [first or second] an audio presentation [parts] part along with a system time clock to control a presentation timing of data units of the first or second type; and

11

outputting audio data corresponding to the data units of the first or second type in response to the identification information.

13. The method of claim 12, wherein the audio data of the first type includes accompaniment sound.

14. The method of claim 12, wherein the data units of digital audio data are interleaved with digital video data, and wherein the audio data of the first type includes accompaniment sound and vocals, which are associated with the digital video data.

15. The method of claim 12, further comprising:
comparing the system time clock to timing information in the digital audio data; and
outputting the audio data with a timing based on the comparison.

16. The [device] method of claim 12, wherein the separating step includes [MPEG decoding] decoding the audio data encoded in MPEG format.

17. The device of claim 1, wherein the [signal] audio data processor includes a switch [that] configured to selectively [outputs] output the data units of the first type or the second type.

18. A recording medium on which digital audio data is recorded, the digital audio data comprising of data units corresponding to at least one of:

- 1) a first type of digital audio data, and
- 2) a second type of digital audio data which includes at least one content different from the first type of digital audio data;

each data unit including supplementary information, which has:

- a) coding information indicating a coding mode of the digital audio data, and

12

b) identification information, different than said coding information, identifying the data unit as one of the first type of digital audio data or the second type of digital audio data wherein the identification information being used for separating the data units of the first type from the data units of the second type stored in a memory and selectively outputting audio data corresponding to the data units of the first or second type, and

c) time information controlling a presentation timing of data units of the first or second type.

19. The recording medium of claim 18, wherein the data unit corresponds to a sector.

20. The recording medium of claim 18, wherein the supplementary information is included in a header of the data unit.

21. The recording medium of claim 18, wherein the first or the second type of audio data is interleaved with digital video data.

22. The recording medium of claim 18, wherein the data units correspond to packets that are multiplexed with each other.

23. The recording medium of claim 18, wherein the coding mode is a coding mode for indicating a MPEG format.

24. The recording medium of claim 18, wherein the time information includes a PTS (Presentation Time Stamp).

25. The recording medium of claim 18, wherein the digital audio data of the first type includes accompaniment sound.

26. The recording medium of claim 18, wherein the digital audio data of the second type includes accompaniment sound and vocal sound.

27. The recording medium of claim 18, wherein the first and second types of digital audio data are decoded based on the coding information.
