ABSTRACT (57)

An adaptive halftoning method where the difference between a digital image and a filtered digital image is introduced into the system on a pixel by pixel basis is disclosed. In this method, each input difference pixel has a corresponding error value of the previous pixel added to the input value at a summing node, resulting in modified image difference data; the modified image difference data is passed to a threshold comparator where the modified image difference data is compared to a threshold value, the threshold value varying according to the properties of the digital image, to determine the appropriate output level; the output level is subtracted from the modified image difference value to produce the input to an error filter; the output of the error filter is multiplied by an adaptation coefficient, where the adaptation coefficient varies according to the properties of the digital image, to generate the error level for the subsequent input pixel; and, the cyclical processing of pixels is continued until the end of the input data is reached.

RENDERING IMAGES UTILIZING ADAPTIVE ERROR DIFFUSION

Matter enclosed in heavy brackets [] appears in the original patent but forms no part of this reissue specification; matter printed in italics indicates the additions made by reissue.

BACKGROUND OF THE INVENTION

1. Field of the Invention

The present invention relates to the rendering of digital image data, and in particular, to the binary or multilevel representation of images for printing or display purposes

2. Background Description

Since images constitute an effective means of communicating information, displaying images should be as convenient as displaying text. However, many display devices, such as laser and ink jet printers, print only in a binary fashion. 20 Furthermore, some image format standards only allow binary images. For example, the WAP1.1 (Wireless Application Protocol) protocol specification allows only for one graphic format, WBMP, a one (1) bit version of the BMP (bitmap) format. Besides allowing only binary images, some image 25 format standards and some displays only allow images of a limited number of pixels. In the WAP 1.1 standard, a WBMP image should not be larger than 150×150 pixels. Some WAP devices have screens that are very limited in terms of the number of pixels. For example, one WAP device has a screen 30 that is 96 pixels wide by 65 pixels high. In order to render a digitized continuous tone input image using a binary output device, the image has to be converted to a binary image.

The process of converting a digitized continuous tone input image to a binary image so that the binary image appears to be 35 a continuous tone image is known as digital halftoning.

In one type of digital halftoning processes, ordered dither digital halftoning, the input digitized continuous tone image is compared, on a pixel by pixel basis, to a threshold taken from a threshold array. Many ordered dither digital halftoning 40 methods suffer from low frequency artifacts. Because the human vision system has greater sensitivity at low frequencies (less than 12 cycles/degree), such low frequency artifacts are very noticeable.

The visibility of low frequency artifacts in ordered dither 45 digital halftoning methods has led to the development of methods producing binary images with a power spectrum having mostly higher frequency content, the so called "blue noise methods".

The most frequently used "blue noise method" is the error 50 diffusion method. In an error diffusion halftoning system, an input digital image I_n (the digitized continuous tone input image) is introduced into the system on a pixel by pixel basis, where n represents the input image pixel number. Each input pixel has its corresponding error value E_{n-1} , where E_{n-1} is the 55 error value of the previous pixel (n-1), added to the input value I_n at a summing node, resulting in modified image data. The modified image data, the sum of the input value and the error value of the previous pixel (I_n+E_{n-1}) , is passed to a threshold comparator. The modified image data is compared 60 to the constant threshold value T._O, to determine the appropriate output level O_n. Once the output level O_n is determined, it is subtracted from the modified image value to produce the input to an error filter. The error filter allocates its input, I_n-O_n , to subsequent pixels based upon an appropriate 65 weighting scheme. Various weighting techniques may be used generate the error level E., for the subsequent input

2

pixel. The cyclical processing of pixels is continued until the end of the input data is reached. (For a more complete description of error diffusion see, for example, "Digital Halftoning", by Robert Ulichney, MIT Press, Cambridge, Mass. and London, England, 1990, pp. 239-319).

Although the error diffusion method presents an improvement over many ordered dither methods, artifacts are still present. There is an inherent edge enhancement in the error diffusion method. Other known artifacts produced by the error diffusion method include artifacts called "worms" and "snowplowing" which degrade image quality.

In U.S. Pat. No. 5,045,952, Eschbach disclosed selectively modifying the threshold level on a pixel by pixel basis in order to increase or decrease the edge enhancement of the output digital image. The improvements disclosed by Eschbach do not allow the control of the edge enhancement by controlling the high frequency portion of the error. Also, the improvements disclosed by Eschbach do not introduce parameters that can be selected to produce the image of the highest perceptual quality at a specific output device.

In U.S. Pat. No. 5,757,976, Shu disclosed utilizing a set of error filters having different sizes for diffusing the input of the error filter among neighboring pixels in predetermined tonal areas of an image and adding "noise" to the threshold in order to achieve a smooth halftone image quality. The improvements disclosed by Shu do not introduce parameters that can be selected to produce the image of the highest perceptual quality at a specific output device.

SUMMARY OF THE INVENTION

It is the primary object of this invention to provide a method for generating a halftone image from a digitized continuous tone input image that provides adjustment of the local contrast of the resulting halftone image, minimizes artifacts and is easily implemented.

It is also an object of this invention to provide a method for generating a halftone image with parameters that can be selected to produce the image of highest quality at a specific output device.

To achieve the objects of this invention, one aspect of this invention includes an adaptive halftoning method where the difference between a digital image and a filtered digital image is introduced into the system on a pixel by pixel basis; each input difference pixel having a corresponding error value, generated from the previous pixels, added to the input value at a summing node, resulting in modified image difference data; the modified image difference data being passed to a threshold comparator where the modified image difference data is compared to a threshold value, the threshold value varying according to the properties of the digital image, to determine the appropriate output level; the output level is subtracted from the modified image difference value to produce the input to an error filter; the output of the error filter is multiplied by a adaptation coefficient, where the adaptation coefficient varies according to the properties of the digital image, to generate the error level for the subsequent input pixel; and, the cyclical processing of pixels is continued until the end of the input data is reached.

In another aspect of this invention, in the method described above, a histogram modification is performed on the image, and the difference between the histogram modified digital image and the filtered digital image is introduced into the system on a pixel by pixel basis.

In still another aspect of this invention, in the method described above, the histogram modification is performed on the difference between the digital image and the filtered digi-

tal image and the histogram modified difference is introduced into the system on a pixel by pixel basis.

In a further aspect of this invention, in the method described above, the selectively changing of the adaptation coefficient comprises dividing the difference between the value at the pixel and the filtered value at the pixel by the filtered value at the pixel, multiplying the absolute value of the result of the division by a first parameter, and adding a second parameter to the result of the multiplication, thereby obtaining the coefficient.

In still another aspect of this invention, in the method described above, the threshold calculation comprises multiplying the filtered value at the pixel by a third parameter.

In still another aspect of this invention, in the method described above and including the adaptation coefficient and threshold calculated as in the two preceding paragraphs, where the filter is a filter of finite extent, the extent of the filter, the first, second parameters and third parameters are selected to produce the image of the highest perceptual quality at a specific output device.

The methods, systems and computer readable code of this invention can be used to generate halftone images in order to obtain images of the highest perceptual quality when rendered on displays and printers. The methods, systems and computer readable code of this invention can also be used to for the design of computer generated holograms and for the encoding of the continuous tone input data.

DESCRIPTION OF THE DRAWINGS

The novel features that are considered characteristic of the invention are set forth with particularity in the appended claims. The invention itself, however, both as to its organization and its method of operation, together with other objects and advantages thereof will be best understood from the 35 following description of the illustrated embodiment when read in connection with the accompanying drawings wherein:

FIG. 1a depicts a block diagram of selected components of an embodiment of a system, of this invention for generating a halftone image from a digitized continuous tone input image, where the histogram modification block is included after the summing node; and,

FIG. 1b depicts a block diagram of selected components of an embodiment of a system of this invention for generating a halftone image from a digitized continuous tone input image, where the histogram modification block is included before the summing node; and,

FIG. 1c depicts a block diagram of selected components of an embodiment of a system of this invention for generating a halftone image from a digitized continuous tone input image, 50 where the adaptation coefficient multiplies the input to the error filter block; and

FIG. 2 depicts a block diagram of selected components of another embodiment of the system of this invention for generating a halftone image from a digitized continuous tone 55 input image; and

FIG. 2a depicts a block diagram of selected components of another embodiment of the system of this invention for generating a halftone image from a digitized continuous tone input image, where the adaptation coefficient multiplies the 60 input to the error filter block.

DETAILED DESCRIPTION

A method and system, for generating a halftone image 65 from a digitized continuous tone input image, that provide adjustment of the local contrast of the resulting halftone

4

image, minimizes artifacts, are easily implemented and contain parameters that can be selected on the basis of device characteristics like brightness, dynamic range, and pixel count, to produce the image of highest perceptual quality at a specific output device are disclosed.

A block diagram of selected components of an embodiment of a system of this invention for generating a halftone image from a digitized continuous tone input image (also referred to as a digital image) is shown in FIG. 1a. Referring to FIG. 1a, image input block 10 introduces an input digital image I_n into the system on a pixel by pixel basis, where n represents the input image pixel number. The input image is also provided to the filtering block 20. The output of filtering block 20 has the form

$$Av_n 32 h(\ldots, I_k, \ldots, I_n, \ldots)$$
 (1)

where h is a functional form spanning a number of pixels. It should be apparent that the input digital image 10 can be a two dimensional array of pixel values and that the array can be represented as a linear array by using such approaches as raster representations or serpentine representation. For a two dimensional array of pixel values, the filter 20 will also be a two dimensional array of filter coefficients and can also be represented as a linear array. The functional forms will be shown in the one dimensional form for ease of interpretation.

In one embodiment: the output of the filtering block 20 has the form

$$Av_n = \{ \sum_{n=N}^{n+N} I_j \} / (2N+1)$$
 (2)

If the filtering block 20 comprises a linear filter, Av_n will be given by a sum of terms, each term comprising the product of an input image pixel value multiplied by a filter coefficient.

It should be apparent that special consideration has to be given to the pixels at the boundaries of the image. For example, the calculations can be started N pixels from the boundary in equation (2). In that case the calculated and halftone image are smaller than the input image. In another case, the image is continued at the boundaries, the continuation pixels having the same value as the boundary pixel. It should be apparent that other methods of taking into account the effect of the boundaries can be used.

The output of the filtering block 20, Av, is subtracted from the input digital image I., at node 25, resulting in a difference value, D_n . In the embodiment in which histogram modification is not included, D_n is the input to a summing node 70. At the summing node 70, a corresponding error value E_{n-1} , where E_{n-1} is the error value accumulated from the previous pixels, is added to the input value D_n resulting in a modified image datum. The modified image data, $D_n + E_{n-1}$, is compared to the output of the threshold calculation block 30 in the threshold comparison block 40 to produce the halftoning output, O_n . (In the case of a binary output device, if the modified image datum is above the threshold, the output level is the white level. Otherwise, the output level is the black level.) Once the output level O_n is determined, it is subtracted from the modified image value to produce the input to an error filter block 50. The error filter block 50 allocates its input, $D_n + E_{n-1} - O_n$, to subsequent pixels based upon an appropriate weighting scheme. The weighted contributions of the error filter block **50** input are stored and all the contributions to the next input pixel are summed to produce the output of the error filter block 50, the error value. The output of the error filter block 50, the error value, is multiplied by the adaptation coefficient in block 60 to generate the error level E., for the subsequent input pixel. The cyclical processing of pixels, as further described below, is continued until the end of the input data is reached.

Referring again to FIG. 1, the input image is also provided to the threshold calculation block 30. The output of the threshold calculation block 30 has the form

$$t(\ldots, I_k, \ldots, I_n, \ldots) \tag{3}$$

where t is a functional form spanning a number of pixels. The form in equation (3) allows the varying of the threshold according to properties of the digital image.

In one embodiment,

$$t(\ldots, I_k, \ldots, I_n, \ldots) = C_0 \{ \sum_{n=N}^{n+N} I_j \} / (2N+1)$$
 (4)

In another embodiment, the output of the threshold calculation block is a linear combination of terms, each term comprising the product of an input image pixel value multiplied by a coefficient. It should be apparent that this embodiment can also be expressed as a function times a parameter. The output of the threshold calculation block 30 is the threshold.

The first pixel value to be processed, I_O , produces a difference value D_O from summing node 25 and produces a value of D_O out of summing node 70 (since E_{-1} is equal to 0). D_O is then compared to the threshold producing an output of O_Q . At summing node 45, O_O is subtracted from D_O to produce the input to the error filter 50. The error filter 50 allocates its 25 input, D_O - O_O , to subsequent pixels based upon an appropriate weighting scheme which determines how much the current input contributes to each subsequent pixel. Various weighting techniques may be used (see, for example, "Digital" Halftoning" by Robert Ulichney, MIT Press, Cambridge, 30 Mass. and London, England, 1990, pp. 239-319). The output of error filter 50 is multiplied by a adaptation coefficient 60. The adaptation coefficient **60** is the output of the coefficient calculation block 80. In one embodiment, the output of the coefficient calculation block 80 has the form

$$C_1+C_2abs\{f(\ldots,I_k,\ldots,I_n,\ldots)/g(\ldots,I_k,\ldots,I_n,\ldots)\}$$
 (5)

where f and g are functional forms spanning a number of pixels. The form of Equation (5) allows the selective changing, of the coefficient according to the local properties of the digital image. C_1 and C_2 and the parameter in the threshold expression can be selected to produce the image of highest perceptual quality at a specific output device.

In another embodiment, the output of the coefficient cal- 45 culation block **80** has the form

$$\begin{array}{c} {\rm C_1+C_2\{abs((I._n-(\{\Sigma_{n-N}^{\quad n+N}I_j\}/(2N+1)))/(\{\Sigma_{n-N}^{\quad n+N}I_j\}/(2N+1))))\}} \\ (2N+1))))\} \end{array} \eqno(6)$$

The input of error filter block **50** is multiplied by weighting coefficients and stored. All the contributions from the stored weighted values to the next pixel are summed to produce the out put of the error filter block **50**. The output of the error filter block **50** is multiplied by the adaptation coefficient **60**. The delay block **65** stores the result of the product of the adaptation coefficient **60** and the output of the error filter block **50**. (In one embodiment, the Floyd-Steinberg filter, the input to the error filter is distributed according to the filter weights to the next pixel in the processing line and to neighboring pixels in the following line.) The output of delay block **65** is E_{n-1} and is delayed by one pixel. (When the first pixel is processed, the output of the delay, E_O , is added to the subsequent difference, D_1 .)

It should be apparent that the sequence order of error filter block **50** and the adaptation coefficient block **60** can be interchanged with similar results. In the embodiment in which the adaptation coefficient **60** multiplies the difference between

6

the modified image datum and the output level, shown in FIG. 1c, the delay block 65 stores the output of the error filter block.

When the next pixel, I_1 , is introduced into the system from the image input block 10, it produces a difference value D_1 from summing node 25 and produce a value of (D_1+E_O) out of summing node 70.

The above steps repeat for each subsequent pixel in the digital image thereby producing a halftone image, the sequence O_O, O_1, \ldots, O_n . The modification of the threshold level and the adaptation coefficient allows control of the amount of edge enhancement and provides the opportunity to reduce artifacts.

In the embodiment in which histogram modification is included after the summing node 25, D_n is the input to the histogram modification block 75 and the output of the histogram modification block 75 is the input to the summing node 70. The above description follows if D_n is replaced by the output of the histogram modification block 75. It should be apparent that histogram modification operates on the entire difference image. (Histogram modification is well known to those skilled in the art. For a discussion of histogram modification, see, for example, Digital Image Processing, by William K. Pratt, John Wiley and Sons, 1978, ISBN 0-471-01888-0, pp. 311-318. For a discussion of histogram equalization, a form of histogram modification, see, for example, Digital Image Processing, by R. C. Gonzalez and P. Wintz, Addison-Wesley Publishing Co., 1977, ISBN 0-201-02596-3, pp. 119-126.)

In the embodiment in which histogram modification is included after the image input block 10, D_n is the difference between the output of the histogram modification block 75 (FIG. 1b) and the filtered image. The above description follows if I_n is replaced by the output of the histogram modification block.

The method described above produces improvements of the error diffusion method by utilizing the difference between the digital image and the filtered digital image as input into the system instead of the digital image, by multiplying the .the output of the error filter by the adaptation coefficient, where the adaptation coefficient varies according to the properties of the digital image, and by using a threshold value that varies according to the properties of the digital image to determine the appropriate output level.

Sample Embodiment

In a specific embodiment, shown in FIG. 2, the output of the filtering block 20, Av_n , is given by Equation (2). The threshold calculation 30 is a function of the output of the filtering block 20 and is given by

$$t(\ldots, I_k, \ldots, I_n, \ldots) = C_O A v_n$$
(7)

which is the same function as in Equation 4 when the output of the filtering block 20, Av_n , is given by Equation (2). The output of the coefficient calculation block 80 depends on the output of the filtering block 20, Av_n , and the difference D_n and is given by

$$C_1+C_2\{abs((D_n-Av_n)/Av_n)\}$$
(8)

When the output of the filtering block 20, Av_n , is given by Equation (2), Equation (8) is the same as Equation (6).

Histogram equalization is included after the summing node **25**. The processing of the input image pixels **10** occurs as described in the preceding section.

The value of N in Equation (2) (the extent of the filter), C_O , C_1 , and C_2 (first, second parameters and third parameters) can be selected to produce the image of highest perceptual quality at a specific output device. For a WBMP image on a specific

monochrome mobile phone display, utilizing a Floyd-Steinberg error filter, the following parameters yield images of high perceptual quality:

N=7,

 $C_{o} = -20$,

 $C_1 = 0.05$, and

 $C_2 = 1$.

In another embodiment, shown in FIG. 2a, the sequence order of error filter block 50 and the adaptation coefficient block 60 are interchanged. In the embodiment of FIG. 2a, in which the 15 adaptation coefficient 60 multiplies the difference between the modified image datum and the output level, the delay block **65** stores the output of the error filter block.

The embodiments described herein can also be expanded to include composite images, such as color images, where 20 each color component might be treated individually by the algorithm. In the case of color input images, the value of N in Equation (2) (the extent of the filter), C_0 , C_1 , and C_2 (first, second parameters and third parameters) can be selected to control the color difference at a color transition while mini- 25 mizing any effects on the brightness at that location. Other possible applications of these embodiments include the design of computer generated holograms and the encoding of the continuous tone input data.

Although the embodiments described herein are most easily understood for binary output devices, the embodiments described herein can also be expanded to include rendering an output image when the number of gray levels in the image exceeds that of obtainable in the rendering device. It should be apparent how to expand the embodiments described herein 35 to M-ary displays or M-ary rendering devices (see, for example, "Digital Halftoning" by Robert Ulichney, MIT Press, Cambridge, Mass., and London, England, 1990, p. 341).

It should be appreciated that the various embodiments 40 described above are provided merely for purposes of example and do not constitute limitations of the present invention. Rather, various other embodiments are also within the scope of the claims, such as the following. The filter 20 can be selected to impart the desired functional behavior of the dif- 45 ference. The filter 20 can, for example, be a DC preserving filter. The threshold 40 and the adaptation coefficient 60 can also be selected to impart the desired characteristics of the image.

It should be apparent that Equations (4) and (5) are exem- 50 plary forms of functional expressions with parameters that can be adjusted. Functional expressions for the threshold and the adaptation coefficient ,where the expressions include parameters that can be adjusted, will satisfy the object of this invention.

In general, the techniques described above may be implemented, for example, in hardware, software, firmware, or any combination thereof. The techniques described above may be implemented in one or more computer programs executing on a programmable computer including a processor, a storage 60 medium readable by the processor (including, for example, volatile and non-volatile memory and/or storage elements), at least one input device, and at least one output device. Program code may be applied to data entered using the input device to perform the functions described and to generate output infor- 65 mation. The output information may be applied to one or more output devices.

8

Elements and components described herein may be further divided into additional components or joined together to form fewer components for performing the same functions.

Each computer program within the scope of the claims 5 below may be implemented in any programming language, such as assembly language, machine language, a high-level procedural programming language, or an object-oriented programming language. The programming language may be a compiled or interpreted programming language. Each com-10 puter program may be implemented in a computer program product tangibly embodied in a machine-readable storage device for execution by a computer processor. Method steps of the invention may be performed by a computer processor executing a program tangibly embodied on a computer-readable medium to perform functions of the invention by operating on input and generating output.

The generation of the halftone image can occur at a location remote from the rendering printer or display. The operations performed in software utilize instructions ("code") that are stored in computer-readable media and store results and intermediate steps in computer-readable media.

Common forms of computer-readable media include, for example, a floppy disk, a flexible disk, hard disk, magnetic tape, or any other magnetic medium, a CDROM, any other optical medium, punch cards, paper tape, any other physical medium with patterns of holes, a RAM, a PROM, and EPROM, a FLASH-EPROM, any other memory chip or cartridge, a carrier wave as described hereinafter, or any other medium from which a computer can read. Electrical, electromagnetic or optical signals that carry digital data streams representing various types of information are exemplary forms of carrier waves transporting the information.

Other embodiments of the invention, including combinations, additions, variations and other modifications of the disclosed embodiments will be obvious to those skilled in the art and are within the scope of the following claims.

What is claimed is:

55

- 1. A method of generating a halftone image from an input digital image, said input digital image represented by a multiplicity of pixels, each pixel having a given value, [said values being stored in a memory, said method comprising the steps of:
 - [(A)] determining [the] one or more properties [including local properties of the *input* digital image;
 - [(B)] filtering the input digital image, said filtering having as output a filtered value at each pixel;
 - [(C)] obtaining the difference between the value at [the] a pixel and the filtered value at the pixel, said difference being a threshold input;
 - [(D)] generating [the] an output state for the pixel depending upon the relationship of the [value of said] threshold input relative to a threshold;
 - (E) producing an error value, said error value being indicative of the deviation of said threshold input from the output state;
 - (F) multiplying said error value by a coefficient, the result of said multiplication being stored;
 - [(G)] combining the stored value with the difference between the next pixel value and the next filtered value to produce a new threshold input;
 - [(H)] repeating [steps (D) through (G)] the generating an output state, the producing an error value, the multiplying said error value, and the combining the stored error value for each pixel in the *input* digital image thereby producing a halftone image; [and]
 - varying the threshold according to the one or more properties of the input digital image; and

- selectively changing the coefficient [in step (E)] according to the [local] *one or more* properties of the *input* digital image.
- 2. The method of claim 1 further comprising [the step of]: performing a histogram modification of the image pixels, 5 before [step (B)] filtering the input digital image.
- 3. The method of claim 1 further comprising the step of: performing a histogram modification of the difference between the value at the pixel and the filtered value at the pixel, before [step (D)] generating the output state.
- 4. The method of claim 1 wherein the selectively changing of the coefficient comprises:
 - dividing a first function of the [local] *pixel* values of the *input* digital image by a second function of the [local] *pixel* values of the *input* digital image; and
 - multiplying the absolute value of the result of said division by a first parameter; and
 - adding a second parameter to the result of the multiplication, thereby obtaining the coefficient.
- 5. The method of claim 4 wherein said first function is the difference between the value at the pixel and the filtered value at the pixel and said second function is the filtered value at the pixel.
- 6. The method of claim 4 wherein the threshold is a third function of the [local] *pixel* values of the *input* digital image. 25
- 7. The method of claim 6 wherein said third function is a linear function of the [local] *pixel* values of the *input* digital image.
- [8. The method of claim 6 wherein said third function is a linear function of the local values of the digital image.]
- 9. The method of claim 4 wherein the threshold is the filtered value at the pixel multiplied by a third parameter.
- 10. The method of claim 9 wherein the [filter in step (B) is] filtering comprises using a filter of finite extent, the extent of the filter, the first parameter, the second [parameters] parameter and the third [parameters] parameter being selected to produce [the] an image of highest perceptual quality at a specific output device.
 - 11. The method of claim 9 further comprising [the step of]: performing a histogram modification of the difference 40 between the value at the pixel and the filtered value at the pixel, before [step (D)] generating the output state.
- 12. The method of claim 1 wherein the input digital image is a monochrome image.
- 13. The method of claim 1 wherein the input digital image 45 is a color image.
- 14. A system for generating a halftone image from an input digital image, said *input* digital image represented by a multiplicity of pixels, each pixel having a given value, [said values being stored in a memory,] said [apparatus] *system* 50 comprising:
 - means for determining [the] *one or more* properties [including local properties] of said *input* digital image; and

means for retrieving the pixel values; and

means for filtering the input digital image, said filtering having as output a filtered value at each pixel; and

55

- means for obtaining the difference between the value at [the] a pixel and the filtered value at the pixel, said difference being a threshold input; and
- means for producing an error value, said error value being indicative of the deviation of said threshold input from [the] *an* output state; and
- means for multiplying said error value by an adaptation coefficient to obtain a diffused value and
- means for storing the diffused value and delaying said stored *diffused* value by one pixel; and

10

- means for combining the stored delayed diffused value with the difference between the pixel value and the filtered value; and
- means for varying [the] a threshold according to the one or more properties of the input digital image at the pixel value; and
- means for selectively changing the adaptation coefficient according to the [local] *one or more* properties of the *input* digital image.
- 15. The system of claim 14 further comprising:
- means performing a histogram modification of the image pixels.
- 16. The system of claim 14 further comprising:
- means for performing a histogram modification of the difference between the value at the pixel and the filtered value at the pixel.
- 17. The system of claim 14 wherein the means for selectively changing of the adaptation coefficient comprise:
 - means for dividing a first function of the [local] *pixel* values of the *input* digital image by a second function of the [local] *pixel* values of the *input* digital image; and
 - means for multiplying the absolute value of the result of said division by a first parameter; and
 - adding a second parameter to the result of the multiplication, thereby obtaining the *adaptation* coefficient.
 - 18. A computer program product comprising:
 - a computer usable *storage* medium having computer readable code embodied therein for generating a halftone image from an input digital image, said *input* digital image represented by a multiplicity of pixels, each pixel having a given value, [said values being stored in a memory,] said code [causing] *comprising instructions for* a computer system [to:], *the instructions comprising:*
 - instructions to determine [the] one or more properties [including local properties] of said input digital image; and

instructions to retrieve the pixel values; and

- instructions to filter the input digital image, said filtering having as output a filtered value at each pixel; and
- [the] a pixel and the filtered value at the pixel, said difference being a threshold input; and
- instructions to produce an error value, said error value being indicative of the deviation of said threshold input from [the] an output state; and
- instructions to multiply said error value by an adaptation coefficient to obtain a diffused value; and
- instructions to store the diffused value and [delaying] delay said stored diffused value by one pixel; and
- instructions to combine the stored delayed diffused value with the difference between the pixel value and the filtered value; and
- instructions to vary [the] a threshold according to the one or more properties of the input digital image at the pixel value; and
- instructions to selectively change the adaptation coefficient according to the [local] one or more properties of the input digital image.
- 19. The computer program product of claim 18 [where, the computer readable code further causes the computer system to] wherein the instructions further comprise:
 - instructions to perform a histogram modification of the image pixels.
- 20. The computer program product of claim 18 [where, the computer readable code further causes the computer system to] wherein the instructions further comprise:

instructions to perform a histogram modification of the difference between the value at the pixel and the filtered value at the pixel.

21. The computer program product of claim 18 [where, the computer readable code in causing the computer system 5 wherein the instructions to selectively change the adaptation coefficient, further causes the computer system to comprise: instructions to divide a first function of the [local] pixel values of the *input* digital image by a second function of the [local] pixel values of the input digital image; and instructions to multiply the absolute value of the result of 10 is a M-ary display or a M-ary rendering device.

said division by a first parameter; and

instructions to add a second parameter to the result of the multiplication, thereby obtaining the adaptation coefficient.

- 22. The computer program product of claim 21 wherein said first function is the difference between the value at the pixel and the filtered value at the pixel and said second function is the filtered value at the pixel.
- 23. The computer program product of claim 22 wherein [said] the threshold is the filtered value at the pixel multiplied by a third parameter.
- 24. The computer program product of claim 23 wherein the filter used to filter the *input* digital image is a filter of finite extent, the extent of the filter, the first parameter, the second [parameters] parameter and third [parameters] parameter being selected to produce [the] an image of highest quality at a specific output device.
- 25. The computer program product of claim [25 where, the computer readable code further causes the computer system to 18 wherein the instructions further comprise:
 - instructions to perform a histogram modification of the difference between the value at the pixel and the filtered value at the pixel.
- 26. The computer program product of claim 21 wherein the threshold is a third function of the [local] *pixel* values of the *input* digital image.
- 27. The computer program product of claim 26 wherein said third function is a linear function of the [local] pixel values of the *input* digital image.
- [28. The computer program product of claim 26 wherein said third function is a linear function of the local values of the digital image.]

- 29. The computer program product of claim 18 wherein the input digital image is a color image.
- 30. The computer program product of claim 18 wherein the input digital image is a monochrome image.
- 31. The system of claim 14, further comprising: a rendering device.
- 32. The system of claim 31, wherein said rendering device is a binary output device.
- 33. The system of claim 31, wherein said rendering device
- 34. The system of claim 31, wherein said rendering device is a mobile phone display.
- 35. A mobile device capable of generating a halftone image from an input digital image, said input digital image represented by a multiplicity of pixels, each pixel having a given value, said mobile device comprising:

means for determining one or more properties of said input digital image;

means for retrieving the pixel values;

means for filtering the input digital image, said filtering having as output a filtered value at each pixel;

means for obtaining the difference between the value at a pixel and the filtered value at the pixel, said difference being a threshold input;

means for producing an error value, said error value being indicative of the deviation of said threshold input from an output state;

means for multiplying said error value by an adaptation coefficient to obtain a diffused value and means for storing the diffused value and delaying said stored diffused value by one pixel;

means for combining the stored delayed diffused value with the difference between the pixel value and the filtered value;

means for varying a threshold according to the one or more properties of the input digital image at the pixel value; means for selectively changing the adaptation coefficient according to the one or more properties of the input

a rendering device.

digital image; and

CERTIFICATE OF CORRECTION

PATENT NO. : RE42,473 E
Page 1 of 1

APPLICATION NO. : 11/847894

DATED : June 21, 2011

INVENTOR(S) : Gorian et al.

It is certified that error appears in the above-identified patent and that said Letters Patent is hereby corrected as shown below:

Title page

Page 3, item (56), under "Other Publications", in Column 2, Line 19, delete "Oct. 2, 2004, U.S. Appl. No. 10/080,833, filed Feb. 22, 2003." and insert -- Mar. 29, 2004, U.S. Appl. No. 10/080,883, filed Feb. 22, 2002. --.

Page 3, item (56), under "Other Publications", in Column 2, Line 21, delete "2003," and insert -- 2004, --.

Page 4, item (56), under "Other Publications", in Column 2, Line 31, delete "Rendenring"," and insert -- Rendering", --.

Column 10, line 12, in Claim 15, delete "means performing" and insert -- means for performing --.

Signed and Sealed this Eleventh Day of October, 2011
