US00RE42918E

(19) **United States**

(12) **Reissued Patent**

Fossum et al.

(10) **Patent Number: US RE42,918 E**

(45) **Date of Reissued Patent: Nov. 15, 2011**

(54) **SINGLE SUBSTRATE CAMERA DEVICE WITH CMOS IMAGE SENSOR**

(75) Inventors: **Eric R. Fossum**, Wolfeboro, NH (US); **Robert Nixon**, Tehachapi, CA (US)

(73) Assignee: **California Institute of Technology**, Pasadena, CA (US)

(21) Appl. No.: **12/421,466**

(22) Filed: **Apr. 9, 2009**

Related U.S. Patent Documents

Reissue of:

(64) Patent No.: **6,549,235**
Issued: **Apr. 15, 2003**
Appl. No.: **09/120,856**
Filed: **Jul. 21, 1998**

U.S. Applications:

(63) Continuation of application No. 08/789,608, filed on Jan. 24, 1997, now Pat. No. 5,841,126, and a continuation-in-part of application No. 08/558,521, filed on Nov. 16, 1995, now Pat. No. 6,101,232, which is a continuation of application No. 08/188,032, filed on Jan. 28, 1994, now Pat. No. 5,471,515.

(60) Provisional application No. 60/010,678, filed on Jan. 26, 1996.

(57) **ABSTRACT**

Single substrate device is formed to have an image acquisition device and a controller. The controller on the substrate controls the system operation.

66 Claims, 10 Drawing Sheets

Defendants Planmeca Oy and Planmeca U.S.A., Inc.'s Answer, Affirmative Defenses, and Counterclaims, May 27, 2010, *Sirona Dental Systems, Inc. and California Institute of Technology* v. *Cefla S.C., et al.*, U.S. District Court for the District of Delaware.
Plaintiffs' First Amended Complaint for Patent Infringement, Jun. 15, 2010, *Sirona Dental Systems, Inc. and California Institute of Technology* v. *Danaher Corporation; Dexis, LLC; Gendex Corp.; Planmeca Oy; and Plameca U.S.A., Inc.*, Civil Action No. 10-288-GMS, U.S. District Court for the District of Delaware.
Plaintiffs' Answer to Defendants Planmeca Oy and Planmeca U.S. A., Inc.'s Counterclaims, Jun. 21, 2010, *Sirona Dental Systems, Inc., et al.* v. *Danaher Corporation, et al.*, Civil Action No. 10-288-GMS, U.S. District Court for the District of Delaware.
Defendants Planmeca Oy and Planmeca U.S.A., Inc.s' Answer to First Amended Complaint, Jun. 29, 2010, *Sirona Dental Systems, Inc., et al.* v. *Danaher Corporation, et al.*, Civil Action No. 10-288-GMS, U.S. District Court for the District of Delaware.
Plaintiffs' Answer to Defendants Planmeca Oy and Planmeca, U.S. A., Inc.'s Counterclaims, Jul. 23, 2010, *Sirona Dental Systems, Inc., et al.* v. *Danaher Corporation, et al.*, Civil Action No. 10-288-GMS, U.S. District Court for the District of Delaware.
Plaintiffs' Second Amended Complaint for Patent infringement, Mar. 4, 2011, *Sirona Dental Systems, Inc., et al.* v. *Danaher Corporation, et al.*, Civil Action No. 10-288-GMS, U.S. District Court for the District of Delaware.
Defendants Planmeca Oy and Planmeca U.S.A., Inc.'s Answer and Counterclaims to the Second Amended Complaint, Mar. 10, 2011, *Sirona Dental Systems, Inc., et al.* v. *Danaher Corporation, et al.*, Civil Action No. 10-288-GMS, U.S. District Court for the District of Delaware.
Plaintiffs' Answer to Defendants Planmeca Oy and Planmeca U.S. A., Inc.'s Counterclaims, Mar. 18, 2011, *Sirona Dental Systems, Inc., et al.* v. *Danaher Corporation, et al.*, Civil Action No. 10-288-GMS, U.S. District Court for the District of Delaware.
Defendants Danaher Corporation, Dexis LLC and Gendex Corp.'s Answer and Counterclaims to Plaintiffs' Second Amended Complaint for Patent Infringement, Mar. 31, 2011, *Sirona Dental Systems, Inc., et al.* v. *Danaher Corporation, et al.*, Civil Action No. 10-288-GMS, U.S. District Court for the District of Delaware.
Defendants Danaher Corporation, Dexis LLC and Gendex Corporation's First Supplemental Responses to Plaintiff Sirona Dental Systems, Inc.'s First Set of Interrogatories (Nos. 1-5, 8-9), Mary 24, 2011, *Sirona Dental Systems, Inc., et al.* v. *Danaher Corporation, et al.*, Civil Action No. 10-288-GMS, U.S. District Court for the District of Delaware.
Complaint for Patent Infringement, Nov. 24, 2010, California Institute of Technology v. STMicroelectronics NV; STMicroelectronics, Inc.; Seti Co., Ltd.; Siliconfile Technologies, Inc.; Toshiba Corp.; Toshiba America Electronics Components, Inc.; LG Electronics, Inc.; LG Electronics Mobilecomm U.S.A., Inc.; Nokia Corp.; Nokia, Inc.; Pantech Co., Ltd.; and Pantech Wireless, Inc., Civil Action No. 2:10-cv-09099-MRP- VBK, Central District of California.
Answer of STMicroelectronics, Inc. to Complaint, Apr. 14, 2011, *California Institute of Technology* v. *STMicroelectronics NV, et al.*, Civil Actions No. 2:10-cv-09099-MRP- VBK, Central District of California.
Defendants Nokia Corp.'s and Nokia, Inc.'s Answer to Plaintiff California Institute of Technology's Complaint, May 19, 2011, *California Institute of Technology* v. *STMicroelectronics NV, et al.*, Civil Actions No. 2:10-cv-09099-MRP- VBK, Central District of California.
Answer and Affirmative Defenses to Plaintiff's Complaint of Pantech Wireless, Inc. and Patech Co., Ltd., and Counterclaims of Pantech Wireless, Inc., May 19, 2011, *California Institute of Technology* v. *STMicroelectronics NV, et al.*, Civil Actions No. 2:10-cv-09099-MRP- VBK, Central District of California.
Defendant Toshiba Corporation's Original Answer with Affirmative Defenses to California Institute of Technology's Complaint for Patent Infringement, May 19, 2011, *California Institute of Technology* v. *STMicroelectronics NV, et al.*, Civil Actions No. 2:10-cv-09099-MRP- VBK, Central District of California.
Defendant Toshiba America Electronic Components, Inc.'s Original Answer with Affirmative Defenses to California Institute of Technology's Complaint for Patent Infringement, May 19, 2011, *California Institute of Technology* v. *STMicroelectronics NV, et al.*, Civil Actions No. 2:10-cv-09099-MRP- VBK, Central District of California.
Defendants/Counterclaim Plaintiffs LG Electronics, U.S.A. Inc.'s Answer and Counterclaim, May 19, 2011, *California Institute of Technology* v. *STMicroelectronics NV, et al.*, Civil Actions No. 2:10-cv-09099-MRP- VBK, Central District of California.
Defendants/Counterclaim Plaintiffs LG Electronics, Inc. and LG Electronics MobileComm U.S.A., Inc.'s Answer and Counterclaim, May 19, 2011, *California Institute of Technology* v. *STMicroelectronics NV, et al.*, Civil Actions No. 2:10-cv-09099-MRP- VBK, Central District of California.

ORIGIN

The invention described herein was made in performance of work under NASA contract and is subject to the provisions of Public Law 96-517 (35 USC 202) in which the contractor has elected to retain title.

FIELD OF THE INVENTION

The present invention relates to a single chip imaging sensor.

BACKGROUND AND SUMMARY OF THE INVENTION

Imaging technology is the science of converting an image to a signal indicative thereof. Imaging systems have broad applications in many fields, including commercial, consumer, industrial, medical, defense and scientific markets.

The original image sensors included an array of photosensitive elements in series with switching elements. Each photosensitive element received an image of a portion of the scene being imaged. That portion is called a picture element or pixel. The image obtaining elements produce an electrical signal indicative of the image plus a noise component. Various techniques have been used in the art to minimize the noise, to thereby produce an output signal that closely follows the image.

Size minimization is also important. The development of the solid state charge coupled device ("CCD") in the early 1970's led to more compact image systems. CCDs use a process of repeated lateral transfer of charge in an MOS electrode-based analog shift register. Photo-generated signal electrons are read after they are shifted into appropriate positions. However, the shifting process requires high fidelity and low loss. A specialized semiconductor fabrication process was used to obtain these characteristics.

CCDs are mostly capacitive devices and hence dissipate very little power. The major power dissipation in a CCD system is from the support electronics. One reason for this problem is because of the realities of forming a CCD system.

The specialized semiconductor fabrication process alluded to above is not generally CMOS compatible. Hence, the support circuitry for such a CCD has been formed using control electronics which were not generally CMOS compatible. The

control electronics have dissipated an inordinate percentage of the power in such imaging devices. For example, CCD-based camcorder imaging systems typically operate for an hour on an 1800 mA-hr 6 V NiCad rechargeable battery, corresponding to 10.8 W of power consumption. Approximately 8 watts of this is dissipated in the imaging system. The rest is used by the tape recording system, display, and autofocus servos.

Space-based imaging systems often have similar problems. The space based systems operate at lower pixel rates, but with a lower degree of integration, and typically dissipate 20 watts or more.

The CCD has many characteristics which cause it to act like a chip-sized MOS capacitor. The large capacitance of the MOS device, for example, requires large clock swings, ΔV, of the order of 5-15 V to achieve high charge transfer efficiency. The clock drive electronics dissipation is proportional to $C\Delta V^2 f$, and hence becomes large. In addition, the need for various CCD clocking voltages (e.g. 7 or more different voltage levels) leads to numerous power supplies with their attendant inefficiencies in conversion.

Signal chain electronics that perform correlated double sampling ("CDS") for noise reduction and amplification, and especially analog to digital converters (ADC), also dissipate significant power.

The inventors also noted other inefficiencies in imaging systems. These inefficiencies included fill factor inefficiencies, fixed pattern noise, clock pick up, temporal noise and large pixel size.

Active pixel sensors, such as described in U.S. Pat. No. 5,471,515, the disclosure of which is incorporated by reference herein, use special techniques to integrate both the photodetector and the readout amplifier into the pixel area or adjacent the pixel area. This allows the signal indicative of the pixel to be read out directly. These techniques have enabled use of a logic family whose fabrication processes are compatible with CMOS. This has enabled the controlling circuitry to be made from CMOS or some other low power-dissipating logic family.

The inventors of the present invention have recognized techniques and special efficiencies that are obtained by specialized support electronics that are integrated onto the same substrate as the photosensitive element. Aspects of the present invention include integration, timing, control electronics, signal chain electronics, A/D conversion, and other important control systems integrated on the same substrate as the photosensitive element.

It is hence an object of the present invention to provide for the integration of an entire imaging system on a chip.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. **1** shows a basic block diagram of a CMOS active pixel circuit;

FIG. **2** shows a graph of typical APS quantum efficiency;

FIG. **3** shows the block diagram of the overall chip including drivers and controlling structures;

FIGS. **4**A and **4**B show the timing diagrams for photogate operation and photodiode operation, respectively;

[FIG. **5** shows] *FIGS. 5A and 5B show* a schematic of the active pixel sensor unit cell and readout circuitry;

FIG. **6** shows a timing diagram for setup and readout;

FIG. **7** shows a drawing of an actual layout of the pixel and control circuitry;

FIG. **8** shows a block diagram of a CMOS APS chip; and

FIG. **9** shows an exemplary pixel layout.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

An active pixel sensor is herewith described with reference to FIGS. **1**-**4**.

A block diagram of a CMOS active pixel circuit is shown in FIG. **1**. The device has a pixel circuit **150**, and a column circuit **155**.

Incident photons pass through the photogate ("PG") **100** in the pixel circuit **150** and generate electrons which are integrated and stored under PG **100**. A number of the pixel circuits are arranged in each row of the circuit. One of the rows is selected for readout by enabling the row selection transistor **102** ("RS").

In the preferred embodiment, the floating diffusion output node **104** ("FD") is first reset by pulsing reset transistor ("RST") **106**. The resultant voltage on FD **104** is read out from the pixel circuitry onto the column bus **112** using the source follower **110** within the pixel. The voltage on the column bus **112** is sampled onto a first holding capacitor **114** by pulsing transistor SHR **116**. This initial charge is used as the baseline.

The signal charge is then transferred to FD **104** by pulsing PG **100** low. The voltage on FD **104** drops in proportion to the number of photoelectrons and the capacitance of FD. The new voltage on the column bus **112** is sampled onto a second capacitor **118** by pulsing SHR **120**. The difference between the voltages on first capacitor **114** and second capacitor **118** is therefore indicative of the number of photoelectrons that were allowed to enter the floating diffusion.

The capacitors **114**, **118** are preferably 1-4 pf capacitors.

All pixels on a selected row are processed simultaneously and sampled onto capacitor at the bottom of their respective columns. The column-parallel sampling process typically takes 1-10 μsec, and preferably occurs during the so-called horizontal blanking interval of a video image.

Each column is successively selected for read-out by turning on column selection p-channel transistors ("CS") **130**. The p-channel source-followers **122**, **124** in the column respectively drive the signal (SIG) and horizontal reset (RST) bus lines. These lines are loaded by p-channel load transistors which can be sent directly to a pad for off-chip drive, or can be buffered.

Noise in the sensor is preferably suppressed by the above-described correlated double sampling ("CDS") between the pixel output just after reset, before and after signal charge transfer to FD as described above. The CDS suppresses kTC noise from pixel reset, suppresses 1/f noise from the in-pixel source follower, and suppresses fixed pattern noise (FPN) originating from pixel-to-pixel variation in source follower threshold voltage.

The inventors found, however, that kTC noise may be reintroduced by sampling the signal onto the capacitors **114**, **118** at the bottom of the column. Typical output noise measured in CMOS APS arrays is of the order of 140-170 μV/e–, corresponding to noise of the order of 13-25 electrons r.m.s. This is similar to noise obtained in most commercial CCDs, through scientific CCDs have been reported with read noise in the 3-5 electrons rms.

Typical biasing for each column's source-follower is 10 μA. This permits charging of the sampling capacitors in the allotted time. The source-followers can then be turned off by cutting the voltage on each load transistor.

The sampling average power dissipation P_s corresponds to:

$$P_s = nIVd$$

where n is number of columns, I is the load transistor bias, V is the supply voltage, and d is the duty cycle. Using n=512, I=μA, V=5V and d=10%, a value for Ps of 2.5 mW is obtained.

A load current of 1 mA or more is needed to drive the horizontal bus lines at the video scan rate. The power dissipated is typically 5 mW.

Quantum efficiency measured in this CMOS APS array is similar to that for interline CCDs. A typical response curve is shown in FIG. **2**. The inventors noticed from this that the quantum efficiency reflects significant responsivity in the "dead" part of the pixel; the part containing the readout circuitry rather than the photogate collector. The responsiveness was measured by intra-pixel laser spot scanning.

The inventors postulate the following reason. The transistor gate and channel absorb photons with short absorption lengths (i.e. blue/green). However, longer wavelength photons penetrate through these regions. The subsequently-generated carriers diffuse laterally and are subsequently collected by the photogate.

Thus, despite a fill factor of 25%-30%, the CMOS APS achieves quantum efficiencies that peak between 30%-35% in the red and near infrared. Microlenses are preferably added to refract photoelectrons from the dead part to a live part and hence improve quantum efficiency.

An important feature of the system described herein is the integration of on-chip timing and control circuits within the same substrate that houses the pixel array and the signal chain electronics. A block diagram of the chip architecture is shown in FIG. **3**.

The analog outputs VS_out (signal) and VR_out (reset) are as described above. The digital outputs include FRAME and READ. Most of the inputs to the chip are asynchronous digital signals, as described herein.

The chip includes a pixel array **300**, which is driven by on-chip electronics. Timing and control circuit **302** drives row electronics **310**, and column electronics **320**.

The control circuits can command read-out of any area of interest within the array. Row decoder **312** controls row drivers **314** which can select a certain row for readout. A specific row is selected by entry of a row value **316** which is output from timing and control **302**. Row value **316** is stored in latch **318** which drives counter **319**. Counter **319** can allow selection of subsequent rows that follow the current row. Similarly, columns can be selected and accessed by latches **322**, counter **324**, decoder **326** and column signal conditioning **328**.

Each of the decoder counters can be preset to start and stop at any value that has been loaded into the chip via the 8-bit data bus **330**. Therefore, as described above, selection of a row commands pixels in that row to be transferred to the appropriate row decoding elements, e.g., capacitors. Preferably there is one capacitor associated with each column. This provides for the sequential readout of rows using the column. The capacitors are preferably included within the column signal conditioner **328**. Column decoders **326** also allow selection of only a certain column to be read. There are two parts of each column selection: where to start reading, and where to stop reading. Preferably the operation is carried out using counters and registers. A binary up-counter within the decoder **326** is preset to the start value. A preset number of rows is used by loading the 2's compliment. The up counter then counts up until an overflow.

An alternate loading command is provided using the DEFAULT LOAD input line **332**. Activation of this line forces all counters to a readout window of 128×128.

A programmable integration time is set by adjusting the delay between the end of one frame and the beginning of the next. This parameter is set by loading a 32-bit latch via the input data bus **330**. A 32-bit counter operates from one-fourth the clock input frequency and is preset at each frame from the latch. The counter can hence provide vary large integration

delays. The input clock can be any frequency up to about 10 MHZ. The pixel readout rate is tied to one-fourth the clock rate. Thus, frame rate is determined by the clock frequency, the window settings, and the delay integration time. The integration time is therefore equal to the delay time and the readout time for a 2.5 MHZ clock. The maximum delay time is 2^{32}/2.5 MHZ, or around 28 minutes. These values therefore easily allow obtaining a 30 Hz frame.

The timing and control circuit controls the phase generation to generate the sequences for accessing the rows. The sequences must occur in a specified order. However, different sequences are used for different modes of operation. The system is selectable between the photodiode mode of operation and the photogate mode of operation. The timing diagrams for the two gates are respectively shown in FIGS. **4**a and **4**b. FIG. **4**a shows an operation to operate in the photogate mode and FIG. **4**b shows operating in the photodiode mode. These different timing diagrams show that different column operations are possible. Conceptually this is done as follows. Column fixed pattern noise is based on differences in source follower thresholds between the different transistors. For example, if the base bias on a transistor is V**1**, the output is V**1** plus the threshold.

The column signal conditioning circuitry contains a double-delta sampling fixed pattern noise ("FPN") suppression stage that reduces FPN to below 0.2% sat with a random distribution. Since the APS is formed of a logic family that is compatible with CMOS, e.g., NMOS, the circuitry can be formed of CMOS. This allows power dissipation in the timing and control digital circuitry to be minimized and to scale with clock rate.

An active pixel sensor includes both a photodetector and the readout amplifier integrated within the same substrate as the light collecting device, e.g., the photodiode. The readout amplifier is preferably within and/or associated with a pixel.

A first embodiment of the present invention is a 128×128 CMOS photodiode type active pixel sensor that includes on chip timing, control and signal train electronics. A more detailed drawing of the chip is shown in [FIG. **5**] *FIGS. 5A and 5B*. Asynchronous digital signals are converted by this chip to VS and VR analog outputs which are used to run the chip.

Pixel portion **500** includes a photodiode **502** which stores incident photons under photogate **504**. The photons are integrated as electrons within the photogate well. The output is buffered by follower **508**.

The rows are arranged into an array. A particular row is selected by the row transistor **514**. This allows the information from within the selected pixel **500** to be passed to the column decoder circuitry. Reset transistor **530** is connected to a sink **532**. Reset transistor is biased to a low potential level to allow all charge to bleed to sink **532**, and hence hold the stored charge in reset. The system is removed from reset by biasing the gate to a level as shown. This level is less than a highest possible potential to thereby allow charge which accumulates above that level to pass to sink **532**. Hence, the charge cannot overflow in an undesired way. This suppresses the blooming effect.

The depicted photogate system is driven according to the readout sequence shown in FIG. **6**. A row is selected by activating row selecting transistor **514**. The cycle begins by sampling the signal present on each column pixel in that row. Sampling is initiated by biasing transistor **526** to place the signal from each column pixel in the row onto the holding capacitor **510**.

After the current pixel value has been transferred to the capacitor **510**, the pixel in the row is reset by biasing reset transistor to a low level, to photodiode **502** to the preset voltage sink **532**.

Correlated double sampling is effected by sampling the reset value, as a reset level, onto the holding capacitor **512**. This is done by activating the reset transistor **516**.

The voltage value of the reset branch of the column circuit is given by

$$Vcol\_R \cong \beta\{\alpha[V_{pdr} - V_{tpix}] - V_{tcolr}\}$$

Where α is the gain of the pixel source follower **508**, β is the gain of the column source follower **526**, and V_{pdr} is the voltage on the photodiode after reset, V_{tpix} is the threshold voltage of the pixel source follower and channel transistor, and V_{tcolr} is the threshold voltage of the column source follower p-channel transistor.

Using similar reasoning, the output voltage of the signal branch of the column circuit is

$$Vcol\_S \cong \beta\{\alpha[V_{pds} - V_{tpix}] - V_{tcols}\}$$

where V_{pds} is the voltage on the photodiode with the signal charge present and V_{tcols} is the threshold voltage of the column source-follower p-channel transistor.

The inventors have found experimentally that the peak-to-peak variation $V_{tcolr} - V_{tcols}$ is typically between 10 and 20 millivolts. This, however, is a source of column to column fixed pattern noise. The inventors herein suggest a double delta sampling technique to eliminate this column to column noise. The present approach represents an improved version of the previously-described double delta sampling circuitry. The operation proceeds as follows. A column is first selected. After a settling time equivalent to half of the column selection period, a special double delta sampling technique is performed to remove the column fixed pattern noise. Therefore, the varying thresholds on the different transistors cause varying outputs. According to this aspect, the threshold outputs of these transistors are equalized using a capacitor to equalize the charge. The capacitor is applied with the charge before and after the voltage change. Therefore, the output of the capacitor represents the difference between before and after, and the fixed pattern noise component drops out of the equation.

This system uses a DDS switch **520** and first and second column select switches **522**, **524** to short across the respective capacitors. All three switches are turned on to short across the two sample and hold capacitors **510**. This clamp operation is shown in line **8** of FIG. **6**.

Prior to the DDS operation, the reset and signal column components, Vcol_R and Vcol_S include their signal values plus a source follower voltage threshold component from the appropriate source follower. The object of the special following circuit of the present invention is to remove that source follower threshold component. The operation proceeds as follows. Prior to the beginning of some operation, the capacitors are precharged through clamp transistors to a clamp voltage V_{cl}. This is maintained by turning on clamp transistors **550** and **552** to connect the appropriate capacitors to the voltage V_{cl}. The clamp operation is shown on line **8** of FIG. **6**. Immediately after the clamp is released, the DDS transistors **520**, **522** and **524** are turned on. This has the effect of shorting across the capacitors **510** and **512**. When the transistors are shorted, the voltage that is applied to the output drivers **554**, **556** includes only the voltage threshold component. The differential amplification of the voltage render the output volt-

age free of the voltage threshold component. Mathematically, prior to clamp being deactivated, the output signals are:

$$VR\_OUT \cong \gamma(V_{cl}-V_{tr})$$

and

$$VS\_OUT \cong \beta(V_{cl}-V_{ts})$$

where γ is the gain of the third stage source-follower, V_{cl} is the clamp voltage, and V_{tr} and V_{ts} are the threshold voltages of the third stage source-follower n-channel transistors, reset and signal branch respectively. Deactivation of the clamp circuit and simultaneous activation of the DDS switch causes several changes. The voltages in the two column branch sampling circuits equalize becoming:

$$V_{cs}=V_{cr}=\alpha[V_{pdr}-V_{tpix}+V_{pds}-V_{tpix}]/2$$

This in turn causes a change in Vcol_S and Vcol_R to:

$$Vcol\_R' \cong \beta\{\alpha[V_{pdr}-V_{tpix}+V_{pds}-V_{tpix}]/2-V_{tcolr}\}$$

and

$$Vcol\_S' \cong \beta\{\alpha[V_{pdr}-V_{tpix}+V_{pds}-V_{tpix}]/2-V_{tcols}\}$$

Consequently, the voltage outputs change to:

$$VR\_OUT \cong \gamma(V_{cl}-Vcol\_R'-Vcol\_R-V_{tr})$$

and

$$VS\_OUT \cong \gamma(V_{cl}-Vcol\_S'-Vcol\_S-V_{ts})$$

We note

$$Vcol\_S'-Vcol\_S=\beta\{\alpha[V_{pds}-V_{pdr}]/2\}$$

and

$$Vcol\_R'-Vcol\_R=\beta\{\alpha[V_{pdr}-V_{pds}]/2\}$$

When the outputs are differentially amplified off-chip, the common clamp voltage Vcl is removed, leaving only the difference between signal and reset. The net differential output voltage is given by:

$$VR\_OUT-VS\_OUT=\alpha\beta\gamma(V_{pdr}-V_{pds}=V_{const})$$

FIG. **7** shows the layout of the pixel for 128×128 array size device. This system formed a 19.2 micron pixel size using 1.2 μm n-well CMOS. The maximum clock rate is 10 MHZ, the maximum pixel rate is 2.5 MHZ and maximum integration delay is 1.6×10^9 clock periods.

A second embodiment uses similar design techniques to produce a 256×256 array size. This embodiment also uses a pixel with a photogate imaging element along with four transistors to perform the functions of readout, selection, and reset. Readout is preferably achieved using a column parallel architecture which is multiplexed one row at a time and then one column at a time through an on-chip amplifier/buffer. An important part of this embodiment, like the first embodiment, is the use of a chip common logic elements to control row and address decoders and delay counters.

This embodiment allows use in three modes of operation: Photogate mode, photodiode mode and differencing mode. The photogate mode is the standard mode for this chip. The photodiode mode alters the readout timing to be similar to that for photodiode operation. The differencing mode alters the readout timing in such a way that the value of each pixel output is the difference between the current frame and the previous frame. The chip inputs that are required are a single +5 V power supply, start command, and parallel data load commands for defining integration time and windowing parameters. The output has two differential analog channels.

The second embodiment uses the block diagram of the chip architecture shown in FIG. **8**. The analog outputs of VS_OUT (signal) and VR_OUT (reset), and digital outputs of FRAME and READ. The inputs to the chip are asynchronous digital signals. The chip includes addressing circuitry allowing readout of any area of interest within the 256×256 array. The decoder includes counters that are preset to start and stop at any value that has been loaded into the chip via the 8-bit data bus. An alternate loading command is provided using the DEFAULT input line. Activation of this line forces all counters to a readout window of 256×256.

A programmable integration time is set by adjusting the delay between the end of one frame and the beginning of the next. This parameter is set by loading a 32-bit latch via the input data bus. A 32-bit counter operates from one-fourth the clock input frequency and is preset at each frame from the latch. This counter allows forming very large integration delays. The input clock can be any frequency up to about 10 MHZ. The pixel readout rate is tied to one fourth the clock rate. Thus, frame rate is determined by the clock frequency, the window settings, and the delay integration time. A 30 HZ frame rate can be achieved without difficulty.

The chip is idle when the RUN command is deactivated. This is the recommended time for setting the operating parameters. However, these parameters can be set at any time because of the asynchronous nature of operation. When RUN is activated, the chip begins continuous readout of frames based on the parameters loaded in the control registers. When RUN is deactivated, the frame in progress runs to completion and then stops.

The 256×256 CMOS APS uses a system having a similar block diagram to those described previously. The pixel unit cell has a photogate (PG), a source-follower input transistor, a row selection transistor and a reset transistor. A load transistor VLN and two output branches to store the reset and signal levels are located at the bottom of each column of pixels. Each branch has a sample and hold capacitor (CS or CR) with a sampling switch (SHS or SHR) and a source-follower with a column-selection switch (COL). The reset and signal levels are read out differentially, allowing correlated double sampling to suppress 1/f noise and fixed pattern noise (not kTC noise) from the pixel.

A double delta sampling (DDS) circuit shorts the sampled signals during the readout cycle reducing column fixed pattern noise. These readout circuits are common to an entire column of pixels. The load transistors of the second set of source followers (VLP) and the subsequent clamp circuits and output source followers are common to the entire array. After a row has been selected, each pixel is reset (RESET) and the reset value is sampled (SHR) onto the holding capacitor CR. Next, the charge under each photogate in the row is transferred to the floating diffusion (FD). This is followed by sampling this level (SHS) onto holding capacitor CS. These signals are then placed on the output data bus by the column select circuitry. In the Photodiode mode this process, is reversed; first the charge under the photogate is read out and then the reset level is sampled. This non-correlated double sampling mode would be primarily used with a photodiode, i.e., non active pixel sensor, pixel.

In the differencing mode, the capacitors CS and CR are used to store the signal from the previous frame and the current frame. This is achieved by altering the timing in the following way: Rather than starting with a reset operation, the signal on the floating diffusion is read out to one of the sample and hold capacitors. This represents the previous pixel value. The reset is then performed followed by a normal read operation. This value is then stored on the other sample and hold capacitor. The difference between these two signals is now the frame to frame difference.

A simplified expression for the output of the reset branch of the column circuit is given by:

$$Vcol\_R = \beta\{\alpha[Vr - V_{tpix}] - V_{tcolr}\}$$

where α is the gain of the pixel source-follower, β is the gain of the column source-follower, Vr is the voltage on the floating diffusion after reset, V_{tpix} is the threshold voltage of the pixel source-follower n-channel transistor, and V_{tcolr} is the threshold voltage of the column source-follower p-channel transistor. Similarly, the output voltage of the signal branch of the column circuit is given by:

$$Vcol\_S = \beta\{\alpha[V_S V_{tpix}] - V_{tcols}\}$$

where V_S is the voltage on the floating diffusion with the signal charge present and V_{tcols} is the threshold voltage of the column source-follower p-channel transistor. Experimentally, the peak to peak variation in V_{tcolr}–V_{tcol} is typically 10-20 mV. It is desirable to remove this source of column-to-column fixed pattern noise FPN. JPL has previously developed a double delta sampling (DDS) technique to eliminate the column-to-column FPN. This approach represented an improved version of the DDS circuitry.

Sequential readout of each column is as follows. First a column is selected. After a settling time equivalent to one-half the column selection period, the DDS is performed to remove column fixed pattern noise. In this operation, a DDS switch and two column selection switches on either side are used to short the two sample and hold capacitors CS and CR. Prior to the DDS operation the reset and signal outputs (Vcol_R and VCOL_S) contain their respective signal values plus a source follower voltage threshold component. The DDS switch is activated immediately after CLAMP is turned off. The result is a difference voltage coupled to the output drivers (VR_OUT and VS_OUT) that is free of the voltage threshold component.

This chip uses a similar pixel cell to that shown in [FIG. **5**] *FIG. 5A*. FIG. **9** shows the layout of the pixel cell. PG and RESET are routed horizontally in polysilicon while the pixel output is routed vertically in [metal1] *metal1*. Metal**2** was routed within the pixel for row selection. Metal**2** was also used as a light shield and covers most of the active area outside of the pixel array. The designed fill factor of the pixel is approximately 21%.

According to another feature, a logo can be formed on the acquired image by using a light blocking metal light shield. The light shield is formed to cover certain pixels in the shape of the logo to be applied. This blocks out those underlying pixels in the array, thereby forming a logo in the shape of the blocked pixels.

The output saturation level of the sensor is 800 mv when operated from a 5 V supply. Saturation is determined by the difference between the reset level on the floating diffusion node (e.g. 3 V) and the minimum voltage allowed on the pixel source follower gate (e.g. threshold voltage of approx. 0.8 volts). This corresponds to a full well of approximately 75,000 electrons. This can be increased by operating at a larger supply voltage, gaining about 47,000 e– per supply volt.

Dark current was measured at less than 500 pA/cm^2.

Conversion gain (μV/e–) was obtained per pixel by plotting the variance in pixel output as a function of mean signal for flat field exposure. The fixed pattern noise arising from dispersion in conversion gain was under 1%—similar to the value found in CCDs and consistent with the well-controlled gain of a source-follower buffer.

The quantum efficiency of the detector was measured using a CVI ¼ m monochromator and a tungsten/halogen light source, calibrated using a photodiode traceable to NIST standards.

What is claimed is:

1. A single chip camera device, comprising:

a substrate, having integrated thereon an image acquisition portion and a control portion, both of which are formed using a logic family that is compatible with CMOS;

said image acquisition portion integrated in said substrate including an array of active pixel type photoreceptors, where each element of the array includes both a photoreceptor and a readout amplifier integrated within the same substrate as the photoreceptor;

said control portion integrated in said substrate including a signal controlling device, controlling said photoreceptors to output their signals,

said control portion also including, integrated in said substrate, a timing circuit integrated within the same substrate that houses the array of photoreceptors, controlling a timing of operation of said array of photoreceptors, and further comprising double sampling charge storage elements on said substrate.

2. A camera device as in claim **1**, wherein said timing circuit includes a timer for first sampling a reset level on a first of said charge storage elements, and then for second sampling a signal level on a second of said charge storage elements.

3. A single chip camera device, comprising:

a substrate, having integrated thereon an image acquisition portion and a control portion, both of which are formed using a logic family that is compatible with CMOS;

said image acquisition portion integrated in said substrate including an array of active pixel type photoreceptors, where each element of the array includes both a photoreceptor and a readout amplifier integrated within the same substrate as the photoreceptor;

said control portion integrated in said substrate including a signal controlling device, controlling said photoreceptors to output their signals,

said control portion also including, integrated in said substrate, a timing circuit integrated within the same substrate that houses the array of photoreceptors, controlling a timing of operation of said array of photoreceptors, wherein said array of photoreceptors are controlled to output an entire row of said photoreceptors substantially simultaneously; and

a plurality of double sampling charge storage elements integrated on said substrate; one for each of said columns.

4. A camera device as in claim **3**, wherein said timing circuit includes a timer for first sampling all reset levels in a specific column on first charge storage elements, and then for second sampling all signal levels on second charge storage elements.

5. A single chip camera device, comprising:

a substrate, having integrated thereon an image acquisition portion and a control portion, both of which are formed using a logic family that is compatible with CMOS;

said image acquisition portion integrated in said substrate including an array of active pixel type photoreceptors, where each element of the array includes both a photoreceptor and a readout amplifier integrated within the same substrate as the photoreceptor;

said control portion integrated in said substrate including a signal controlling device, controlling said photoreceptors to output their signals,

said control portion also including, integrated in said substrate, a timing circuit integrated within the same substrate that houses the array of photoreceptors, controlling a timing of operation of said array of photoreceptors, wherein said signal controlling device includes a column selector allowing selection of a desired **[**colum**]** *column* for read**[]**out, and a row selector which allows selection of a desired row **[**fro**]** *for* readout.

6. A camera device as in claim **5**, wherein said row selector includes a latch element, storing a value for a row to be selected, and a counter, allowing incrementing of said value to read a next consecutive row, said latch element and said counter both being integrated in said substrate.

7. A single chip camera device, comprising:

a substrate, having integrated thereon an image acquisition portion and a control portion, both of which are formed using a logic family that is compatible with CMOS;

said image acquisition portion integrated in said substrate including an array of photoreceptors;

said control portion integrated in said substrate including a signal controlling device, controlling said photoreceptors to output their signals, in a way such that at least a plurality of said photoreceptors output their signals at substantially the same time,

said control portion also including, integrated in said substrate, a timing circuit integrated within the same substrate that houses the array of photoreceptors, controlling a timing of operation of said array of photoreceptors,

wherein said signal controlling device includes a column selector allowing selection of a desired column for read out, and a row selector which allows selection of a desired row for readout,

wherein said row selector includes a latch element, storing a value for a row to be selected, and a counter, allowing incrementing of said value to read a next consecutive row, said latch element and said counter both being integrated on said substrate.

8. A single chip camera device, comprising:

a substrate, having integrated thereon an image acquisition portion and a control portion, both of which are formed using a logic family that is compatible with CMOS;

said image acquisition portion integrated in said substrate including an array of photoreceptors;

said control portion integrated in said substrate including a signal controlling device, controlling said photoreceptors to output their signals, in a way such that at least a plurality of said **[**photoreeptors**]** *photoreceptors* output their signals at substantially the same time,

said control portion also including, integrated in said substrate, a timing circuit integrated within the same substrate that houses the array of photoreceptors, controlling a timing of operation of said array of photoreceptors, wherein said signal controlling device includes a column selector allowing selection of a desired column for read out, and a row selector which allows selection of a desired row for readout, wherein said **[**colum**]** *column* selector includes presettable start and stop column decoder counters, which are preset to start and stop at any desired value.

9. A camera device as in claim **8**, further comprising an input data bus, connected to the camera device, values on said data bus being used to preset said start and stop column decoder counters.

10. A single chip camera device, comprising:

a substrate, having integrated thereon an image acquisition portion and a control portion, both of which are formed using a logic family that is compatible with CMOS;

said image acquisition portion integrated in said substrate including an array of photoreceptors;

said control portion integrated in said substrate including a signal controlling device, controlling said photoreceptors to output their signals, in a way such that at least a plurality of said photoreceptors output their signals at substantially the same time,

said control portion also including, integrated in said substrate, a timing circuit integrated within the same substrate that houses the array of photoreceptors, controlling a timing of operation of said array of photoreceptors, further comprising a mode selector device, selecting a mode of operation of said chip,

wherein said photoreceptors are either photogates or photodiodes, and said mode selector device selects a first mode of operation for operation with photogates, and second mode of operation, different that said first mode of operation, for operation with photodiodes.

11. A camera device as in claim **10**, further comprising a differencing mode which alters readout timing in such a way that the value of each pixel output represents a difference between a current frame and a previous frame.

12. A single chip camera device, comprising:

a substrate, having integrated thereon an image acquisition portion and a control portion, both of which are formed using a logic family that is compatible with CMOS;

said image acquisition portion integrated in said substrate including an array of photoreceptors;

said control portion integrated in said substrate including a signal controlling device, controlling said photoreceptors to output their signals, in a way such that at least a plurality of said photoreceptors output their signals at substantially the same time,

said control portion also including, integrated in said substrate, a timing circuit integrated within the same substrate that houses the array of photoreceptors, controlling a timing of operation of said array of photoreceptors, and

further comprising a correlated double sampling circuit.

13. A single chip camera device, comprising:

a substrate, having integrated thereon an image acquisition portion and a control portion, both of which are formed using a logic family that is compatible with CMOS;

said image acquisition portion integrated in said substrate including an array of photoreceptors;

said control portion integrated in said substrate including a signal controlling device, controlling said photoreceptors to output their signals, in a way such that at least a plurality of said photoreceptors output their signals at substantially the same time,

said control portion also including, integrated in said substrate, a timing circuit integrated within the same substrate that houses the array of photoreceptors, controlling a timing of operation of said array of photoreceptors,

wherein said timing circuit controls readout from said chip in a correlated double sampling mode.

14. A single chip camera device, comprising:

a substrate, having integrated thereon an image acquisition portion and a control portion, both of which are formed using a logic family that is compatible with CMOS;

said image acquisition portion integrated in said substrate including an array of photoreceptors;

said control portion integrated in said substrate including a signal controlling device, controlling said photoreceptors to output their signals, in a way such that a least a plurality of said photoreceptors output their signals at substantially the same time,

said control portion also including, integrated in said substrate, a timing circuit integrated within the same substrate that houses the array of photoreceptors, controlling a timing of operation of said array of photoreceptors,

wherein said timing circuit allows changing an integration time for said array of photoreceptors.

15. A single chip camera device, comprising:

a substrate, having integrated thereon an image acquisition portion and a control portion, both of which are formed using a logic family that is compatible with CMOS;

said image acquisition portion integrated in said substrate including an array of photoreceptors;

said control portion integrated in said substrate including a signal controlling device, controlling said photoreceptors to output their signals, in a way such that at least a plurality of said photoreceptors output their signals at substantially the same time,

said control portion also including, integrated in said substrate, a timing circuit integrated within the same substrate that houses the array of photoreceptors, controlling a timing of operation of said array of photoreceptors, and

further comprising fixed pattern noise reduction circuits, on said substrate.

16. A single chip camera device, comprising:

a substrate, having integrated thereon an image acquisition portion and a control portion, both of which are formed using a logic family that is compatible with CMOS;

said image acquisition portion integrated in said substrate including an array of photoreceptors;

said control portion integrated in said substrate including a signal controlling device, controlling said photoreceptors to output their signals, in a way such that at least a plurality of said photoreceptors output their signals at substantially the same time,

said control portion also including, integrated in said substrate, a timing circuit integrated within the same substrate that houses the array of photoreceptors, controlling a timing of operation of said array of photoreceptors, further comprising a noise reduction circuit,

wherein said timing circuit times an operation of said noise reduction circuit to occur during a time of the video signal which is not being displayed.

17. A single chip camera device, comprising:

a substrate, having integrated thereon an image acquisition portion and a control portion, both of which are formed using a logic family that is compatible with CMOS;

said image acquisition portion integrated in said substrate including an array of photoreceptors;

said control portion integrated in said substrate including a signal controlling device, controlling said photoreceptors to output their signals, in a way such that a least a plurality of said photoreceptors output their signals at substantially the same time,

said control portion also including, integrated in said substrate, a timing circuit integrated within the same substrate that houses the array of photoreceptors, controlling a timing of operation of said array of photoreceptors, and a noise reduction circuit.

18. A single chip camera device, comprising:

a substrate, having integrated thereon an image acquisition portion and a control portion, both of which are formed using a logic family that is compatible with CMOS;

said image acquisition portion integrated in said substrate including an array of photoreceptors;

said control portion integrated in said substrate including a signal controlling device, controlling said photoreceptors to output their signals, in a way such that at least a plurality of said photoreceptors output their signals at substantially the same time,

said control portion also including, integrated in said substrate, a timing circuit integrated within the same substrate that houses the array of photoreceptors, controlling a timing of operation of said array of photoreceptors, further comprising a mode selector device, selecting a mode of operation of said chip,

wherein said photoreceptors are either photogates or photodiodes, and said mode selector device selects a first mode of operation for operation with photogates, and second mode of operation, different that said first mode of operation, for operation with photodiodes.

19. A single chip camera device, comprising:

a substrate, having integrated thereon an image acquisition portion and a control portion, both of which are formed using a logic family that is compatible with CMOS;

said image acquisition portion integrated in said substrate including an array of photoreceptors;

said control portion integrated in said substrate including a signal controlling device, controlling said photoreceptors to output their signals, and including a preset buffer, allowing present of at least one of a start address for output or a stop address for output;

said control portion also including, integrated in said substrate, a timing circuit integrated within the same substrate that houses the array of photoreceptors, controlling a timing of operation of said array of photoreceptors.

20. A camera device as in claim **19**, wherein said signal controlling device includes a column-parallel read out device, which reads out a row of said photoreceptors at substantially the same time.

21. A camera device as in claim **20**, wherein said signal controlling device includes a column selector allowing selection of a desired column for read out, and a row selector which allows selection of a desired row for readout.

22. A camera device as in claim **19**, further comprising an input data bus, connected to the camera device, values on said data bus being used to preset said start and stop values.

23. A camera device as in claim **19**, wherein said photoreceptors are photodiodes.

24. A camera device as in claim **19**, wherein said photoreceptors are photogates.

25. A camera device as in claim **19**, wherein said photoreceptors are either photogates or photodiodes, further comprising a mode selector device which selects a first mode of operation for operation with photogates, and a second mode of operation, different than said first mode of operation, for operation with photodiodes.

26. A camera device as in claim **25**, further comprising a differencing mode which alters readout timing in such a way that the value of each pixel output represents a difference between a current frame and a previous frame.

27. A camera device as in claim **19**, further comprising a correlated double sampling circuit integrated on the chip.

28. A camera device as in claim 19, wherein said timing circuit controls readout from said chip in a correlated double sampling mode.

29. A single chip camera device, comprising:

a substrate, having integrated thereon an image acquisition portion and a control portion, both of which are formed using a logic family that is compatible with CMOS;

said image acquisition portion integrated in said substrate including an array of photoreceptors;

said control portion integrated in said substrate including a signal controlling device, controlling said photoreceptors to output their signals, and including a preset buffer, allowing preset of at least one of a start address for output or a stop address for output;

said control portion also including, integrated in said substrate, a timing circuit integrated within the same substrate that houses the array of photoreceptors, controlling a timing of operation of said array of photoreceptors, wherein said array of photoreceptors includes an active pixel sensor, where each element of the array includes both a photoreceptor and a readout amplifier integrated within the same substrate as the photoreceptor.

30. A camera device as in claim 29, wherein said readout amplifier is preferably within and/or associated with one element of the array.

31. A single chip camera device, comprising:

a substrate, having integrated thereon an image acquisition portion and a control portion, both of which are formed using a logic family that is compatible with CMOS;

said image acquisition portion integrated in said substrate including an array of photoreceptors;

said control portion integrated in said substrate including a signal controlling device, controlling said photoreceptors to output their signals, and including a preset buffer, allowing preset of at least one of a start address for output or a stop address for output;

said control portion also including, integrated in said substrate, a timing circuit integrated within the same substrate that houses the array of photoreceptors, controlling a timing of operation of said array of photoreceptors, and a noise reduction circuit.

32. A single chip camera device, comprising:

a substrate, having integrated thereon an image acquisition portion and a control portion, both of which are formed using a logic family that is compatible with CMOS;

said image acquisition portion integrated in said substrate including an array of photoreceptors;

said control portion integrated in said substrate including a signal controlling device, controlling said photoreceptors to output their signals, and including a preset buffer, allowing preset of at least one of a start address for output or a stop address for output;

said control portion also including, integrated in said substrate, a timing circuit integrated within the same substrate that houses the array of photoreceptors, controlling a timing of operation of said array of photoreceptors, and a noise reduction circuit.

33. A camera device as in claim 32, wherein said timing circuit times an operation of said noise reduction circuit to occur during a time of the video signal which is not being displayed.

34. A single chip camera device, comprising:

a substrate, having integrated thereon an image acquisition portion and a control portion, both of which are formed using a logic family that is compatible with CMOS;

said image acquisition portion integrated in said substrate including an array of photoreceptors;

said control portion integrated in said substrate including a signal controlling device, controlling said photoreceptors to output their signals,

said control portion also including, integrated in said substrate, a timing circuit integrated within the same substrate that houses the array of photoreceptors, controlling a timing of operation of said array of photoreceptors in a first mode or in a second mode, depending on a type of photoreceptor being used.

35. A camera device as in claim 34, wherein said photoreceptor is one of a photodiode or a photogate, and said array is controlled into said first mode for said photogate and in said second mode for said photodiode.

36. A camera device as in claim 35, further comprising a correlated double sampling circuit.

37. A camera device as in claim 35, further comprising a differencing mode which alters readout timing in such a way that the value of each pixel output represents a difference between a current frame and a previous frame.

38. A camera device as in claim 35, wherein said timing circuit allows changing an integration time for said array of photoreceptors.

39. A camera device as in claim 38, wherein said timing circuit times an operation of said noise reduction circuit to occur during a time of the video signal which is not being displayed.

40. A camera device as in claim 34, wherein said array of photoreceptors includes an active pixel sensor, where each element of the array includes both a photoreceptor and a readout amplifier integrated within the same substrate as the photoreceptor.

41. A camera device as in claim 40, wherein said readout amplifier is preferably within and/or associated with one element of the array.

42. A single chip camera device, comprising:

a substrate, having integrated thereon an image acquisition portion and a control portion, both of which are formed using a logic family that is compatible with CMOS;

said image acquisition portion integrated in said substrate including an array of photoreceptors;

said control portion integrated in said substrate including a signal controlling device, controlling said photoreceptors to output their signals,

said control portion also including, integrated in said substrate, a timing circuit integrated within the same substrate that houses the array of photoreceptors, controlling a timing of operation of said array of photoreceptors in a first mode or in a second mode, depending on a type of photoreceptor being used, further comprising a noise reduction circuit.

43. A single chip camera device, comprising:

a substrate, having integrated thereon an image acquisition portion and a control portion, both of which are formed using a logic family that is compatible with CMOS;

said image acquisition portion integrated in said substrate including an array of photoreceptors;

said control portion integrated in said substrate including a signal controlling device, controlling said photoreceptors to output their signals,

said control portion also including, integrated in said substrate, a timing circuit integrated within the same substrate that houses the array of photoreceptors, controlling a timing of operation of said array of photoreceptors,

said control portion including common logic elements to control row and address decoders and delay counters.

44. A camera device as in claim **43**, wherein said signal controlling device includes a column-parallel read out device, which reads out a column of said photoreceptors at substantially the same time.

45. A camera device as in claim **44**, further comprising a noise reduction circuits, on chip.

46. A camera device as in claim **45**, wherein said timing circuit times an operation of said noise reduction circuit to occur during a time of the video signal which is not being displayed.

47. A camera device as in claim **45**, wherein said noise reduction circuit is a fixed pattern noise reduction circuit.

48. A camera device as in claim **45**, wherein said noise reduction circuit is a column to column fixed pattern noise reduction circuit.

49. A camera device as in claim **43**, wherein said signal controlling device includes a column selector allowing selection of a desired row for read out, and a row selector which allows selection of a desired row for readout.

50. A camera device as in claim **49** wherein said row selector includes a latch element, storing a value for a row to be selected, and a counter, allowing incrementing of said value to read a next consecutive row, said latch element and said counter both being integrated on said substrate.

51. A camera device as in claim **49**, wherein said column selector includes presettable start and stop column decoder counters, which are preset to start and stop at any desired value.

52. A camera device as in claim **51**, further comprising an input data bus, connected to the camera device, values on said data bus being used to preset said start and stop column decoder counters.

53. A camera device as in claim **43**, wherein said array of photoreceptors includes an active pixel sensor, where each element of the array includes both a photoreceptor and a readout amplifier integrated within the same substrate as the photoreceptor.

54. A camera device as in claim **53**, wherein said readout amplifier is preferably within and/or associated with one element of the array.

55. A camera device as in claim **53**, wherein said photoreceptors are photodiodes.

56. A camera device as in claim **53** wherein said photoreceptors are photogates.

57. A camera device as in claim **43**, further comprising a correlated double sampling circuit.

58. A camera device as in claim **43**, wherein said timing circuit controls readout from said chip in a correlated double sampling mode.

59. A single chip camera device, comprising:

a substrate, having integrated thereon an image acquisition portion and a control portion, both of which are formed using a logic family that is compatible with CMOS;

said image acquisition portion integrated in said substrate including an array of photoreceptors;

said control portion integrated in said substrate including a signal controlling device, controlling said photoreceptors to output their signals,

said control portion also including, integrated in said substrate, a timing circuit integrated within the same substrate that houses the array of photoreceptors, controlling a timing of operation of said array of photoreceptors,

said control portion including common logic elements to control row and address decoders and delay counters, further comprising a mode selector device, selecting a mode of operation of said chip.

60. A camera device as in claim **59**, wherein said photoreceptors are either photogates or photodiodes, and said mode selector device selects a first mode of operation for operation with photogates, and a second mode of operation, different than said first mode of operation, for operation with photodiodes.

61. A camera device as in claim **60**, further comprising a differencing mode which alters readout timing in such a way that the value of each pixel output represents a difference between a current frame and a previous frame.

62. A single chip camera device, comprising:

a substrate, having integrated thereon an image acquisition portion and a control portion, both of which are formed using a logic family that is compatible with CMOS;

said image acquisition portion integrated in said substrate including an array of photoreceptors;

said control portion integrated in said substrate including a signal controlling device, controlling said photoreceptors to output their signals, and including a preset buffer, allowing preset of at least one of a start address for output or a stop address for output;

said control portion also including, integrated in said substrate, a timing circuit integrated within the same substrate that houses the array of photoreceptors, controlling a timing of operation of said array of photoreceptors, wherein said timing circuit allows changing an integration time for said array of photoreceptors.

63. A single chip camera device, comprising:

a substrate, having integrated thereon an image acquisition portion and a control portion, both of which are formed using a logic family that is compatible with CMOS;

said image acquisition portion integrated in said substrate including an array of photoreceptors arranged in row and columns;

a charge storage element, associated with each said columns;

said control portion integrated in said substrate including a signal controlling device, controlling said photoreceptors to output their signals,

said control portion also including, integrated in said substrate, a timing circuit integrated within the same substrate that houses the array of photoreceptors, controlling a timing of operation of said array of photoreceptors;

said control portion including common logic elements to control all pixels on a selected row to sample said all pixels onto said charge storage elements substantially simultaneously, further comprising a mode selector device, selecting a mode of operation of said chip.

64. A single chip camera device, comprising:

a substrate, having integrated thereon an image acquisition portion and a control portion, both of which are formed using a logic family that is compatible with CMOS;

said image acquisition portion integrated in said substrate including an array of photoreceptors arranged in rows and columns;

a charge storage element, associated with each said **[**colum**]** *column*;

said control portion integrated in said substrate including a signal controlling device, controlling said photoreceptors to output their signals,

said control portion also including, integrated in said substrate, a timing circuit integrated within the same sub-

strate that houses the array of photoreceptors, controlling a timing of operation of said array of photoreceptors,

said control portion including common logic elements to control all pixels on a selected row to sample said all pixels onto said charge storage elements substantially simultaneously,

wherein said photoreceptors are either photogates or photodiodes, and said mode selector device selects a first mode of operation for operation with photogates, and a second mode of operation, different than said first mode of operation, for operation with photodiodes.

65. A single chip camera device, comprising:

a substrate, having integrated thereon an image acquisition portion and a control portion, both of which are formed using a logic family that is compatible with CMOS;

said image acquisition portion integrated in said substrate including an array of photoreceptors;

said control portion integrated in said substrate including a signal controlling device, controlling said photoreceptors to output their signals, and including a preset buffer, allowing preset of at least one of a start address for output or a stop address for output;

said control portion also including, integrated in said substrate, a timing circuit integrated within the same substrate that houses the array of photoreceptors, controlling a timing of operation of said array of photoreceptors, wherein said timing circuit allows changing an integration time for said array of photoreceptors.

66. A method of controlling a single chip camera, comprising:

integrating, on a single substrate, an image acquisition portion and a control portion, both of which are formed using a logic family that is compatible with CMOS, said image acquisition portion integrated in said substrate including an array of photoreceptors, and a signal controlling device, controlling said photoreceptors and a timing circuit integrated within the same substrate that houses the array of photoreceptors, controlling a timing of operation of said array of photoreceptors;

determining a first mode of operation for said photoreceptors being photogates, and a second mode of operation for said photoreceptors being photodiodes;

using said on-chip timing and control circuit to control sequences for accessing rows in a specified order depending on said mode of operation, using a first sequence for said first mode of operation for photogates, and a second mode of operation for said second mode for photodiodes, a timing for said first mode being different than a timing for said second mode.
