(57) **ABSTRACT**

Disclosed herein is a non-contact charging system. The non-contact charging system detects a portable terminal, a battery pack or a foreign object that is placed on the pad of a non-contact charger, and effectively monitors and controls its charging state through the detection, thus preventing such a foreign object placed on the pad from being heated by induction heating, and further causes anions to be generated during the charging of the portable terminal or the battery pack, thus sterilizing bacteria on a terminal and keeping ambient air thereof fresh.

## NO POINT OF CONTACT CHARGING SYSTEM

**Matter enclosed in heavy brackets [ ] appears in the original patent but forms no part of this reissue specification; matter printed in italics indicates the additions made by reissue.**

### TECHNICAL FIELD

The present invention relates, in general, to a no point of contact charging system and, more particularly, to a no point of contact charging system, which detects a portable terminal, a battery pack or a foreign object that is placed on the pad of a non-contact charger, and effectively monitors and controls its charging state through the detection, thus preventing such a foreign object placed on the pad, from being heated by induction heating, and which causes anions to be generated during the charging of the portable terminal or the battery pack, thus destroying bacteria on a terminal and keeping nearby ambient air fresh.

### BACKGROUND ART

Generally, as communication and information processing technology are developed, the use of portable devices, such as mobile phones, that are convenient to carry is gradually increasing. With the development of technology, there is a trend in which new model terminals, the efficiency of which is improved, are being frequently popularized.

For the charging of such a portable device, a contact type charging scheme, or a non-contact charging scheme, which charges a battery using magnetic coupling without electrical contact, in order to solve the problems of the contact type charging scheme that result from the exposure of the contact terminals to the outside, is being used.

In relation to technology corresponding to such a non-contact charger, a scheme that performs charging by wireless communication between a battery pack and a charging device using a magnetic body core, such as unexamined Korean Pat. No. 2002-0035242 previously filed, entitled "Contactless Type Charging Device Of Storage Battery For Mobile Device Using Induction Coupling," and a scheme that solves the problem of the magnetic body core using a transformer in which a wire is formed on a printed circuit substrate, such as previously filed unexamined Korean Pat. No. 2002-0057469, entitled "Coreless Ultra Thin Type Printed Circuit Substrate Transformer And Non-contact Battery Charger Using Printed Circuit Substrate Transformer," have been proposed.

The present applicant proposed technology that constructs a wireless charging pad for performing a non-contact charging function, is configured such that the battery pack of a portable device is placed on the wireless charging pad for performing a non-contact charging function and, therefore, allows non-contact charging to be performed through "Wireless Charging Pad And Battery Pack Employing Radio Frequency Identification Technology (previously filed Korean Appl. No. 2004-48286)."

However, when detecting the portable device or the battery pack placed on the non-contact charging pad, the conventional technology depends on a scheme for transmitting Radio Frequency (RF) carrier signals to the outside through a reader antenna, and then detecting whether return signals exist, so that it is problematic in that the detection of the battery pack and the monitoring and controlling of the charging state through the detection are limitedly performed.

2

Furthermore, in the case in which a coin, a metal pen, a pair of scissors or the like (hereinafter referred to as a foreign object), other than the battery pack or the portable device, are placed on the non-contact charging pad, power transmission is continuously performed, so that a problem occurs in that the foreign object placed on the non-contact charging pad is heated by induction heating.

Furthermore, the non-contact charging pad only has a function of charging terminals or battery packs, so that a problem occurs in that the efficiency thereof is lowered.

### DISCLOSURE

#### Technical Problem

Accordingly, the present invention has been made keeping in mind the above problems occurring in the prior art, and an object of the present invention is to provide a non-contact charging system that detects a portable terminal, a battery pack or a foreign object placed on a non-contact charging pad according to a type, and monitors and controls its charging state through the detection, thus preventing such a foreign object placed on the pad from being heated to high temperature.

Another object of the present invention is to provide a non-contact charging system, in which a function of sterilizing a terminal is provided to a non-contact charging pad and causes anions to be generated therefrom, thus enabling sanitary use of the terminal and keeping ambient air nearby thereof fresh.

A further object of the present invention is to provide a non-contact charging system, in which a primary core unit included in a non-contact charging pad is provided in a form such that the center portion thereof may be passed through, so that the structure thereof is simplified, charging is available at a defined location and, therefore, the usage efficiency thereof can be increased.

#### Technical Solution

In order to accomplish the above objects, the present invention provides a non-contact charging system having a battery pack (B) charged by an induced electromotive force generated from a non-contact charger (A) supplied with power, wherein the non-contact charger (A) includes an electromagnetic wave filter (100) connected to a power input terminal to block electromagnetic waves caused by Alternating Current (AC) power; a primary rectification circuit (110) for rectifying the AC power, the electromagnetic waves of which are blocked, to Direct Current (DC) power; a flyback converter (110') for storing power transferred from the primary rectification circuit (110) while a contained transistor is turned on, and applying an input voltage to a gate driver (160), a central processing unit (180) and an ion generation unit (182) and applying a driving voltage to a series resonance type converter (120) when the contained transistor is turned off; a current detection unit (170) interposed between the flyback converter (110') and the series resonance type converter (120) to detect variation in current resulting from the approach of the battery pack (B), and outputting a comparison current depending on variation in current; a central processing unit (180) for detecting the approach of the battery pack (B) using the comparison current input from the current detection unit (170), controlling the gate drive (160) according not only to whether the battery pack (B) approaches but also to the current of a temperature protection circuit unit (183) to stop the switching of the gate drive (160) when abnormal operation

occurs or a temperature of a foreign object placed on the non-contact charging pad exceeds a predetermined temperature; a gate driver (160) for outputting gate signals under control of the central processing unit (180); the series resonance type converter (120) for adjusting the waveforms of voltage and current applied to a primary core unit (130) in response to the gate signals input from the gate driver (160); and the primary core unit (130) switched by the series resonance type converter (120) to generate the induced electromotive force.

The gate driver (160) allows two switching devices, which are provided in the series resonance type converter (120), to be alternately turned on in response to the gate signals output under the control of the central processing unit (180), thus adjusting the waveforms of the input voltage and current through charging and discharging parallel capacitors coupled to respective switching devices.

The current detection unit (170) is connected to both ends of a resistor connected to an output terminal of the flyback converter (110') and an input terminal of the series resonance type converter (120), includes a differential amplifier (171) to which signals output from both ends of the resistor are input, and a comparator/low frequency filter (172) which is coupled to an output terminal of the differential amplifier (171), and detects variation in current by comparing the output voltage of the differential amplifier (171) with a predetermined reference voltage, filters out a comparison current depending on variation in current, and outputs the comparison current.

The central processing unit (180) is configured to process information fed back from a dust and odor sensor (181) and switch the operation mode of the ion generation unit (182).

The primary core unit (130) is configured such that coils (Pcoil1 and Pcoil2) are wound around a plate core member (131) in which a central opening (132) is formed.

The plate core member (131) is formed in a polygonal shape, a circular shape, or elliptical shape, and is configured such that pieces of amorphous metal or ferrite material are attached thereto.

The coils (Pcoil1 and Pcoil2) are wound around the plate core member (131) in series or in parallel.

The battery pack (B) includes a secondary core unit (210) configured to induce power through the primary core unit (130); a secondary rectification circuit unit (200) coupled to the coil (Scoil1) of the secondary core unit (120) to rectify the induced power; a charging control unit (230) comprising a charging adjustment circuit (230a) for supplying a fuel gauge (230b) with power rectified by the secondary rectification circuit (200), and applying voltage to a Radio Frequency Identification (RFID) control unit in response to the output of the secondary rectification circuit 200, and the fuel gauge (210b) for supplying a battery BAT through a protection circuit (240) with power supplied from the charging adjustment circuit (230a), and generating charging state information and periodically records the information while monitoring the charging state of the battery BAT; and a protection circuit unit (240) coupled between the charging control unit (230) and the battery (BAT) to control whether to perform charging or discharging depending on a charged state of the battery (BAT).

A shield plate (260) having a film shape is interposed between the secondary core unit (210) of the battery pack (B) and a battery case (250), and the protection circuit unit (240) is surrounded by a shield member (241).

The charging control unit (230) is formed by integrating circuits optimized to perform both a charging control function of controlling the charging and discharging of the battery (BAT) using the power rectified by the secondary rectification

circuit (200), and a fuel gauge function of generating the charge state information and periodically recording the generated information while monitoring the charging state of the battery (B).

The foreign object detection unit (220) detects instantaneous power at the same time that the battery pack (B) containing the secondary core unit (210) is placed on the wireless charger (A) and allows a no load state to be maintained by maintaining a switch (Q3) in an OFF state for a certain period of time, and allows the no load state to be switched into a load state by maintaining the switch (Q3) in an ON state after the no load state has been maintained for the period of time, thereby informing the primary coil through load modulation that the battery pack (B) containing the secondary core unit (210) has been placed on the non-contact charger (A) and, at the same time, applying power to a charging control unit (230).

#### ADVANTAGEOUS EFFECTS

In accordance with the present invention, components for detecting a portable terminal, a battery pack or a foreign object that is placed on the pad of a non-contact charger, and effectively monitoring and controlling its charging state through the detection are added, so that the efficiency of the entire circuit is improved, and the foreign object can be prevented from being heated by induction heating.

Furthermore, a function of sterilizing a terminal is provided to a non-contact charging pad and also anions are generated therefrom, so that the terminal can be sanitarily used and nearby ambient air thereof can be kept fresh.

Furthermore, a primary core unit included in a non-contact charging pad is provided in a form such that the center portion thereof may be passed through, so that the structure thereof is simplified, charging is available at a defined location and, therefore, the usage efficiency thereof can be increased.

#### DESCRIPTION OF DRAWINGS

FIG. 1 is a block diagram showing the construction of a non-contact charging system according to the present invention;

FIGS. 2 and 3 are perspective views showing a primary core unit disposed in the non-contact charging system according to the present invention;

FIGS. 4, 5 and 6 are perspective views showing the use of the primary core unit disposed in the non-contact charging system according to the present invention;

FIG. 7 is a view showing a direction of rotation of a magnetic field depending on each mode of operation in a series resonance type converter provided in the non-contact charging system according to the present invention;

FIG. 8 is a perspective view showing the construction of a battery pack provided in the non-contact charging system according to the present invention;

FIG. 9 is a diagram illustrating an algorithm that executes when a battery pack, in which a secondary core unit is contained, is placed on the non-contact charging system according to the present invention;

FIG. 10 is a diagram illustrating an algorithm that execute when a foreign object made of metal is placed on the non-contact charging system according to the present invention; and

FIG. 11 is a diagram illustrating the algorithm and state of the non-contact charging system according to the present invention.

An embodiment of the present invention is described in detail with reference to the accompanying drawings below.

When it is determined that details of well-known functions or constructions related to descriptions of the present invention may unnecessarily make the gist of the present invention unclear, the details will be omitted.

FIG. 1 is a block diagram showing the construction of a non-contact charging system according to the present invention.

The non-contact charging system according to the present invention includes a battery pack B charged by an induced electromotive force that is generated in a non-contact charger A supplied with power.

The non-contact charger A, as shown in FIG. 1, blocks electromagnetic waves caused by Alternating Current (AC) power (110/220V) input using an electromagnetic wave filter 100 that is connected to the power input terminal of a wireless charging pad, and a primary rectification circuit 110 rectifies the AC power, the electromagnetic waves of which are blocked, to create DC power. A flyback converter 110' contains a transistor, stores power transferred from the primary rectification circuit 110 while the contained transistor is turned on. In contrast, the flyback converter 110' simultaneously applies an input voltage to a gate driver 160, a central processing unit 180 and an ion generation unit 182 and a driving voltage to a series resonance type converter 120 when the contained transistor is turned off.

A current detection unit 170 is interposed between the flyback converter 110' and the series resonance type converter 120, detects variation in current resulting from the approach of the battery pack B, and outputs a comparison current depending on variation in the current.

For this purpose, the current detection unit 170 is connected to both ends of a resistor connected to the output terminal of the flyback converter 110' and the input terminal of the series resonance type converter 120, has a differential amplifier 171, to which signals output from both ends of the resistor are input, and a comparator/low-frequency filter 172, coupled to the output terminal of the differential amplifier 171. The current detection unit 170 detects variation in current by comparing the output voltage of the differential amplifier 171 with a predetermined reference voltage, filters out a comparison current depending on the amount of variation in current, and outputs the result.

The central processing unit 180 detects the approach of the battery pack B using the comparison current input from the current detection unit 170, controls the gate drive 160 depending not only on whether a battery pack B approaches but also on the current of a temperature protection circuit unit 183 for stopping the switching of the gate drive 160 when abnormal operation occurs or the temperature of a foreign object placed on the non-contact charging pad exceeds a predetermined temperature. Furthermore, the central processing unit 180 performs the determination of information fed back from a dust and odor sensor 181 and switches the operation mode of the ion generation unit 182.

The gate driver 160 outputs gate signals under the control of the central processing unit 180, and the series resonance type converter 120 adjusts the waveforms of voltage and current applied to the primary core unit 130 in response to the gate signals input from the gate driver 160.

For this purpose, the gate driver 160 allows two switching devices, which are provided in the series resonance type converter 120, to be alternately turned on in response to the gate signals output by the control of the central processing

unit 180, and allows the waveforms of the input voltage and current to be adjusted by charging and discharging parallel capacitors coupled to respective switching devices.

The series resonance type converter 120 is configured to adjust the waveforms of the voltage and the current applied to the primary core unit 130 by the gate signals. The primary core unit 130 is configured to be switched by the series resonance type converter 120 and, therefore, generate an induced electromotive force.

FIGS. 2 and 3 are perspective views showing a primary core unit disposed in the non-contact charging system according to the present invention, and FIGS. 4, 5 and 6 are perspective views showing the use of the primary core unit disposed in the non-contact charging system according to the present invention.

As shown in the drawings, the primary core unit 130 is configured such that coils Pcoil1 and Pcoil2 are wound around a plate core member 131 in which a central opening 132 is formed, and is configured such that pieces of amorphous metal or ferrite material, such as Cobalt Co, Iron Fe, Nickel Ni, Boron B or Silicon Si, having high magnetic permeability (>80,000) and an unbroken characteristic, are attached thereto. Although the plate core member 131 is formed in a polygonal shape, it may be formed in either circular or elliptical shapes in addition to the polygonal shape. The central opening 132 is configured such that a function, which is capable both of reducing the amount of material used and of maximizing the area for radiating heat, is provided.

The coils Pcoil1 and Pcoil2 are configured to be wound around the plate core member 131 in series or in parallel, and it is preferable to use a single wire, a paired wire, a Litz wire or a copper foil. The start points of the coils Pcoil1 and Pcoil2 are formed by winding the coils in the same directions, and the ends of the coils Pcoil1 and Pcoil2 are configured to be matched with Lr and Lr', respectively, and to be switched using two series resonance type converters.

In this case, driven switching adjusts the phase of a signal Q1 and the phase of a signal Q2, thus inducing LC resonance, so that energy is stored in a secondary coil.

Furthermore, the switching patterns of the coils Pcoil1 and Pcoil2 are alternately generated, so that a magnetic field shown in FIG. 7 rotates 360°, and induced energy can be stored regardless of the location of the secondary coil wound in a single direction.

Meanwhile, when the primary core unit 130 having the construction shown in FIGS. 4 and 5 is placed on one or both sides of a circuit 134 and is then used, a plurality of portable terminals or battery packs may be charged at the same time, so that the efficiency thereof can be increased.

Furthermore, as shown in FIG. 6, primary core units 130 and 130' can be placed on one side of the circuit 134 in series or parallel.

In the battery pack B, as shown in FIG. 1, resonance is induced while power generated from the primary coil passes a resonance capacitor Cs through the coil Scoil1 of the secondary core unit 120, and a sinusoidal AC generated by the resonance is rectified into a Direct Current (DC) by the secondary rectification circuit 200.

Power rectified by the secondary rectification circuit 200 is supplied to a foreign object detection unit 220, and the supplied power is applied to a charging adjustment circuit 230a in response to the output of the foreign object detection unit 220.

In this case, the foreign object detection unit 220 detects power at the moment at which the battery pack B that contains the secondary core unit 210, that is, a secondary module, is placed on the non-contact charger A, and is maintained in a no load state (the current of the current detection unit is smaller

than a no load reference value) by maintaining a switch Q3 in an OFF state for a predetermined time (several tens of ms). When a predetermined period of time has lapsed after the no load state, the foreign object detection unit 220 is switched into a load state (the current of the current detection unit is larger than the no load reference value) by maintaining the switch Q3 in an ON state, and informs the primary coil through load modulation that the battery pack B containing the secondary core unit 210 has been placed on the non-contact charger A and, at the same time, applies power to a charging control unit 230.

Subsequently, the current of the current detection unit 170 becomes smaller than the reference value of the no load state when the charging is completed and, at the same time, the secondary core unit 210 enters the no load state again, so that a fully-charging state is indicated by a Light Emitting Diode (LED) or a Liquid Crystal Display (LCD).

The charging control unit 230 includes the charging adjustment circuit 230a and a fuel gauge 230b, and performs both charging adjustment and fuel gauge functions. The charging adjustment circuit 230a supplies the fuel gauge 230b with power rectified by the secondary rectification circuit 200, and applies voltage to a RFID control unit (not shown) in response to the output of the secondary rectification circuit 200. The fuel gauge 230b supplies a battery BAT through a protection circuit 240 with power supplied from the charging adjustment circuit 230a, generates charging state information and periodically records the information in the RFID control unit (not shown) while monitoring the charging state of the battery BAT. The protection unit is coupled between the charging control unit 230 and the battery BAT, and adjusts the charging and discharging of the battery BAT depending on whether the battery BAT is to be charged or discharged.

In the RFID control unit (not shown), the RFID information of the battery BAT is stored and, at the same time, the charging state information is periodically recorded. When receiving an RF carrier, the RFID control unit generates RFID data, including the stored RFID and charging state information of the battery BAT, in response to the received RF carrier, modulates the RFID data, and wirelessly transmits the modulated RFID data through a tag antenna. The battery BAT is charged depending on the adjustment of the protection circuit unit 240.

The charging control unit 230 is formed by integrating circuits optimized to perform both the charging control function of controlling the charging and discharging of the battery BAT using the power rectified by the secondary rectification circuit 200, and the fuel gauge function of generating the charge state information and periodically recording the generated information while monitoring the charging state of the battery B.

FIG. 8 is a perspective view showing the construction of the battery pack provided in the non-contact charging system according to the present invention. As shown in FIG. 8, the battery pack B is configured such that a shield plate 260 having a film shape is interposed between the secondary core unit 210 and a battery case 250, thus preventing the temperature of the battery BAT from increasing due to an induced electromotive force generated by the induction of an electromagnetic field and, therefore, enhancing the stability of the battery pack B, and is also configured such that sufficient electromotive force is generated by reducing the interference of the electromagnetic field caused by the induced electromotive force, thus enhancing the charging rate.

Furthermore, when a shield member 241 that is capable of blocking the electromagnetic field is provided so as to surround the protection circuit unit 240, it is prevented from

affecting different components provided inside the protection circuit unit 240. The shield member 241 is formed in a box form so as to surround the protection circuit unit 240. It is preferred that the entire protection circuit unit 240 is formed by molding.

An example of a process of charging the battery pack B using the wireless charging pad is described with reference to FIGS. 9 to 11 below.

FIG. 9 is a diagram illustrating an algorithm that executes when a battery pack, in which a secondary core unit is contained, is placed in the non-contact charging system according to the present invention. FIG. 10 is a diagram illustrating an algorithm that executes when a foreign object, which is made of metal, is placed on the non-contact charging system according to the present invention. FIG. 11 is a diagram illustrating the algorithm and states of the non-contact charging system according to the present invention.

First, the foreign detection unit 220 detects instantaneous power at the same time that a battery pack B is placed on the wireless charging pad, and allows a no load state to be maintained by maintaining the switch Q3 in an OFF state for a certain period of time.

Thereafter, the foreign detection unit 220 maintains the state at which the current of the current detection unit 170 becomes smaller than the no load reference value for the period of time, and then allows the no load state to be switched into a load state by maintaining the switch Q3 in an ON state. At this time, the current of the current detection unit 170 becomes larger than the no load reference value, so that the foreign object detection unit 220 informs the primary coil through load modulation that a battery pack B containing a secondary core unit 210 has been placed on the non-contact charger A and, at the same time, applies power to the charging control unit 230.

Thereafter, the current of the current detection unit 170 becomes smaller than the reference value of the no load state when the charging is completed and, at the same time, the secondary core unit 210 enters the no load state, so that a fully-charging state is indicated by a LED or a LCD.

Meanwhile, the power is applied to the charging control unit 230, and the operation mode of the ion generation unit 182 is switched by allowing the central processing unit 180 to determine information fed back from the odor sensor 181, so that a plurality of ions generated by the ion generation unit 182, are spread to the area around the wireless charging pad. Accordingly, the bacteria on the battery pack can be destroyed and, at the same time, the ambient air near the wireless charging pad can be purified.

Meanwhile, the switch Q3 is maintained in an OFF state for a certain period of time and the no load state is maintained by detecting instantaneous power at the same time that a battery pack B is placed on the wireless charging pad, and a current below the reference value is supplied and is then blocked by the central processing unit 180 to which the currents of the current detection unit 170 and the temperature protection circuit unit 183 are applied, so that damage caused by overheating is prevented.

The above-described present invention can be variously modified according to the demand of those skilled in the art within the range without departing from the fundamental concept of the present invention.

The invention claimed is:

1. A non-contact charging system having a battery pack (B) charged by an induced electromotive force generated from a non-contact charger (A) supplied with power, wherein the non-contact charger (A) comprises: an electromagnetic wave filter (100) connected to a power input terminal to block

electromagnetic waves caused by Alternating Current (AC) power; a primary rectification circuit (110) for rectifying the AC power, to Direct Current (DC) power; a flyback converter (110') for storing power transferred from the primary rectification circuit (110) while a contained transistor is turned on, and applying an input voltage to a gate driver (160), a central processing unit (180) and applying a driving voltage to a series resonance type converter (120) when the contained transistor is turned off; a current detection unit (170) interposed between the flyback converter (110') and the series resonance type converter (120) to detect a variation in current resulting from an approach of the battery pack (B) to a non-contact charging pad, and outputting a comparison current depending on the variation in current; the central processing unit (180) for detecting the approach of the battery pack (B) using the comparison current output from the current detection unit (170), controlling the gate drive (160) according not only to whether the battery pack (B) approaches but also to the current of a temperature protection circuit unit (183) to stop the switching of the gate drive (160) when abnormal operation occurs or the temperature of a foreign object placed on the non-contact charging pad exceeds a predetermined temperature; the gate driver (160) for outputting gate signals under the control of the central processing unit (180); the series resonance type converter (120) for adjusting the waveforms of voltage and current applied to a primary core unit (130) in response to the gate signals input from the gate driver (160); and the primary core unit (130) switched by the series resonance type converter (120) to generate the induced electromotive force,

wherein the battery pack (B) comprises:

a secondary core unit (210) configured to induce power through the primary core unit (130); a secondary rectification circuit unit (200) coupled to a coil (Scoil1) of the secondary core unit (120) to rectify the induced power; a charging control unit (230) comprising a charging adjustment circuit (230a) for supplying a fuel gauge (230b) with power rectified by the secondary rectification circuit (200), and applying voltage to a Radio Frequency Identification (RFID) control unit in response to the output of the secondary rectification circuit (200), and the fuel gauge (210b) for supplying a battery BAT through a protection circuit (240) with power supplied from the charging adjustment circuit (230a), and generating charging state information and periodically records the information while monitoring the charging state of the battery BAT; and a protection circuit unit (240) coupled between the charging control unit (230) and the battery (BAT) to control whether to perform charging or discharging depending on a charged state of the battery (BAT), and

a shield plate (260) having a film shape, interposed between the secondary core unit (210) of the battery pack (B) and a battery case (250), the protection circuit unit (240) being surrounded by a shield member (241).

2. The non-contact charging system according to claim 1, wherein the gate driver (160) allows two switching devices, which are provided in the series resonance type converter (120), to be alternately turned on in response to the gate signals output under control of the central processing unit (180), thus adjusting the waveforms of the input voltage and current through charging and discharging parallel capacitors coupled to respective switching devices.

3. The non-contact charging system according to claim 1, wherein the current detection unit (170) is connected to both ends of a resistor connected to an output terminal of the flyback converter (110') and an input terminal of the series

resonance type converter (120), comprises a differential amplifier (171) to which signals output from both ends of the resistor are inputted, and a comparator/low frequency filter (172) which is coupled to an output terminal of the differential amplifier (171), and detects the variation in current by comparing the output voltage of the differential amplifier (171) with a predetermined reference voltage, filters out the comparison current depending on variation in current, and outputs the comparison current.

4. The non-contact charging system according to claim 1, wherein the central processing unit (180) is configured to process information fed back from a dust and odor sensor (181) and switch an operation mode of the ion generation unit (182).

5. The non-contact charging system according to claim 1, wherein the primary core unit (130) is configured such that coils (Pcoil1 and Pcoil2) are wound around a plate core member (131) in which a central opening (132) is formed.

6. The non-contact charging system according to claim 5, wherein the plate core member (131) is formed in a polygonal shape, a circular shape, or elliptical shape, and is configured such that pieces of amorphous metal or ferrite material are attached thereto.

7. The non-contact charging system according to claim 5, wherein the coils (Pcoil1 and Pcoil2) are wound around the plate core member (131) in series or in parallel.

8. The non-contact charging system according to claim 1, wherein the charging control unit (230) is formed by integrating circuits optimized to perform both a charging control function of controlling the charging and discharging of the battery (BAT) using the power rectified by the secondary rectification circuit (200), and a fuel gauge function of generating the charge state information and periodically recording the generated information while monitoring the charging state of the battery (B).

9. The non-contact charging system according to claim 1, wherein the foreign object detection unit (220) detects instantaneous power at the same time that the battery pack (B) containing the secondary core unit (210) is placed on the wireless charger (A) and allows a no load state to be maintained by maintaining a switch (Q3) in an OFF state for a certain period of time, and allows the no load state to be switched into a load state by maintaining the switch (Q3) in an ON state after the no load state has been maintained for the period of time, thereby informing the primary coil through load modulation that the battery pack (B) containing the secondary core unit (210) has been placed on the non-contact charger (A) and, at the same time, applying power to a charging control unit (230).

10. A charger for wirelessly charging an electronic device placed on a charging pad of the charger, comprising:

a first and a second terminals that receive a DC voltage signal therebetween;

a converter to adjust the DC voltage signal and provide a switching signal to a primary core unit to generate an induced electromotive force for transmission to the electronic device;

a sensor unit interposed between the first terminal and the converter to sense a variation in one of a voltage and a current between the first terminal and the converter to generate a comparison current based on the sensed variation; and

a processing unit configured to detect an approach of an external object based on the value of the comparison current,

wherein the processing unit is configured to measure the value of the comparison current when no object is

## 11

placed on the charging pad, and stores the value of the comparison current as a reference current value, wherein the processing unit is configured to detect a change in the comparison current, the change in the comparison current being triggered by placing an external object on the charging pad; and wherein the processing unit is configured to obtain a value of the comparison current as an object-presented current value in response to the change in the comparison current, and wherein the processing unit is configured to, in response to a detection of the change in the comparison current by the processing unit, compare the reference current value with the object-presented current value, determine whether the reference current value is less than the object-presented current value, and decide a type of the external object in response to an outcome of the comparison.

11. The charger according to claim 10, wherein the processing unit enables the primary core unit to generate the induced electromotive force in response to a determination that the object-presented current value is less than the reference current value, which is indicative of the external object being a wirelessly chargeable device.

12. The charger according to claim 11, wherein the processing unit is configured to, upon the determination that the object-presented current value is less than the reference current value receive information on an identity of the wirelessly chargeable device through load modulation from the wirelessly chargeable device after a first predetermined period of time.

13. The charger according to claim 10, wherein the processing unit disables the primary core unit from generating the induced electromotive force in response to a determination that the object-presented current value is greater than the reference current value, which is indicative of the external object being a foreign object not suitable for wireless charging.

14. The charger according to claim 10, further comprising a gate driver for outputting a gate signal to the converter under control of the processing unit, wherein the converter adjusts waveforms of the switching signal in response to the gate signal.

15. The charger according to claim 14, further comprising a resistor connected between the first terminal and the converter in parallel to the sensor unit.

16. The charger according to claim 15, wherein the sensor unit comprises a differential amplifier which is connected to the resistor in parallel, and a comparator, which is coupled to an output terminal of the differential amplifier, that senses the variation by comparing an output voltage of the differential amplifier with a predetermined reference voltage, and outputs the comparison current based on a comparison result thereof.

17. The charger according to claim 10, wherein the converter is a series resonance type converter.

18. The charger according to claim 10, further comprising a power generator circuit configured to generate the DC voltage signal based on an external AC power signal and output the DC voltage signal to apply to the first and second terminals.

19. The charger according to claim 18, the power generator circuit comprises a rectification circuit to rectify the external AC power signal.

20. A method of wirelessly charging an electronic device placed on a charging pad of a wireless charger, comprising: receiving a DC voltage signal between a first and a second terminals;

## 12

converting the DC voltage signal by a converter and providing a switching signal to a primary core unit to generate an induced electromotive force for transmission to the electronic device;

sensing a variation in one of a voltage and a current between the first terminal and the converter and generating a comparison current based on the sensed variation of the voltage or the current;

memorizing the value of the comparison current as a reference current value;

detecting a change in the value of the comparison current being triggered by placing an external object on the charging pad;

in response to the change in the comparison current, obtaining a value of the comparison current as an object-presented current value;

comparing the reference current value with the object-presented current value, and determining whether the reference current value is less than the object-presented current value; and deciding a type of the external object in response to the comparison.

21. The method according to claim 20, further comprising: enabling the primary core unit to generate the induced electromotive force in response to a determination that the object-presented current value is less than the reference current value, which is indicative of the external object being a wirelessly chargeable device.

22. The method according to claim 21, further comprising: upon a determination that the object-presented current value is less than the reference current value, receiving information on an identity of the wirelessly chargeable device through load modulation from the wirelessly chargeable device after a first predetermined period of time.

23. The method according to claim 20, further comprising: disabling the primary core unit from generating the induced electromotive force in response to a determination that the object-presented current value is greater than the reference current value, which is indicative of the external object being a foreign object not suitable for wireless charging.

24. An electronic device, comprising:

a battery cell;

an induction coil configured to generate a power signal from a magnetic field applied thereto;

a rectification unit configured to rectify the power signal to generate a rectified power signal;

a foreign object indication unit having a switch, the foreign object indication unit being configured to receive the rectified power signal and transfer the rectified power signal to a charging control unit through the switch; and the charging control unit configured to process the power signal to charge the battery cell with the processed power signal,

wherein the foreign object indication unit is configured to control an on/off state of the switch in response to an instantaneous input of the rectified power, and

wherein the foreign object indication unit turns off the switch in response to start of an input of the rectified power signal to disable the transfer of the rectified power signal to the charging control unit.

25. The electronic device according to claim 24, wherein the foreign object indication unit maintains the off state of the switch for a first predetermined period of time after turning off the switch in response to the start of the input of the rectified

power signal, and thereafter turns on the switch to start transfer of the rectified power signal to the charging control unit.

26. The electronic device according to claim 25, wherein the first predetermined period of time is several tens of milliseconds.

27. The electronic device according to claim 25, wherein the foreign object indication unit is configured to transmit an information signal on an identity of the wirelessly chargeable battery pack by way of load modulation through the induction coil to a wireless charger after the first predetermined period of time has passed.

28. A battery pack, comprising:

a battery cell;

an induction coil configured to generate a power signal from a magnetic field applied thereto;

a rectification unit configured to rectify the power signal to generate a rectified power signal;

a foreign object indication unit having a switch, the foreign object indication unit being configured to receive the rectified power signal and transfer the rectified power signal to a charging control unit through the switch; and the charging control unit configured to process the power signal to charge the battery cell with the processed power signal,

wherein the foreign object indication unit is configured to control an on/off state of the switch in response to an instantaneous input of the rectified power, and

wherein the foreign object indication unit turns off the switch in response to start of an input of the rectified power signal to disable the transfer of the rectified power signal to the charging control unit.

29. The battery pack according to claim 28, wherein the foreign object indication unit maintains the off state of the switch for a first predetermined period of time after turning off the switch in response to the start of the input of the rectified power signal, and thereafter turns on the switch to start transfer of the rectified power signal to the charging control unit.

30. The batter,/pack according to claim 29, wherein the first predetermined period of time is several tens of milliseconds.

31. The batter,/pack according to claim 29, wherein the foreign object indication unit is configured to transmit an information signal on an identity of the wirelessly chargeable battery pack by way of load modulation through the induction coil to a wireless charger after the first predetermined period of time has passed.

32. A method of wirelessly charging a battery pack comprising:

generating a power signal from an induction coil to an externally applied magnetic field;

rectifying the power signal to generate a rectified power signal;

transferring the rectified power signal to a charging control unit through a switch of a foreign object indication unit; and

processing the power signal to charge a battery cell with the processed power signal;

wherein an on/off state of the switch is controlled in response to an instantaneous input of the rectified power, and

wherein the switch is turned off in response to a start of an input of the rectified power signal to disable the transfer of the rectified power signal to the charging control unit.

33. The method according to claim 32, wherein the off state of the switch is maintained for a first predetermined period of time after turning off the switch in response to the start of the input of the rectified power signal, and thereafter the switch is turned on to start transfer of the rectified power signal to the charging control unit.

34. The method according to claim 33, wherein the first predetermined period of time is several tens of milliseconds.

35. The method according to claim 34, further comprising: transmitting an information signal on an identity of the wirelessly chargeable battery pack by way of load modulation through the induction coil to a wireless charger after the first predetermined period of time has passed.

UNITED STATES PATENT AND TRADEMARK OFFICE  
**CERTIFICATE OF CORRECTION**

PATENT NO. : RE44,038 E  
APPLICATION NO. : 12/914303  
DATED : March 5, 2013  
INVENTOR(S) : Ki-young Cho

Page 1 of 1

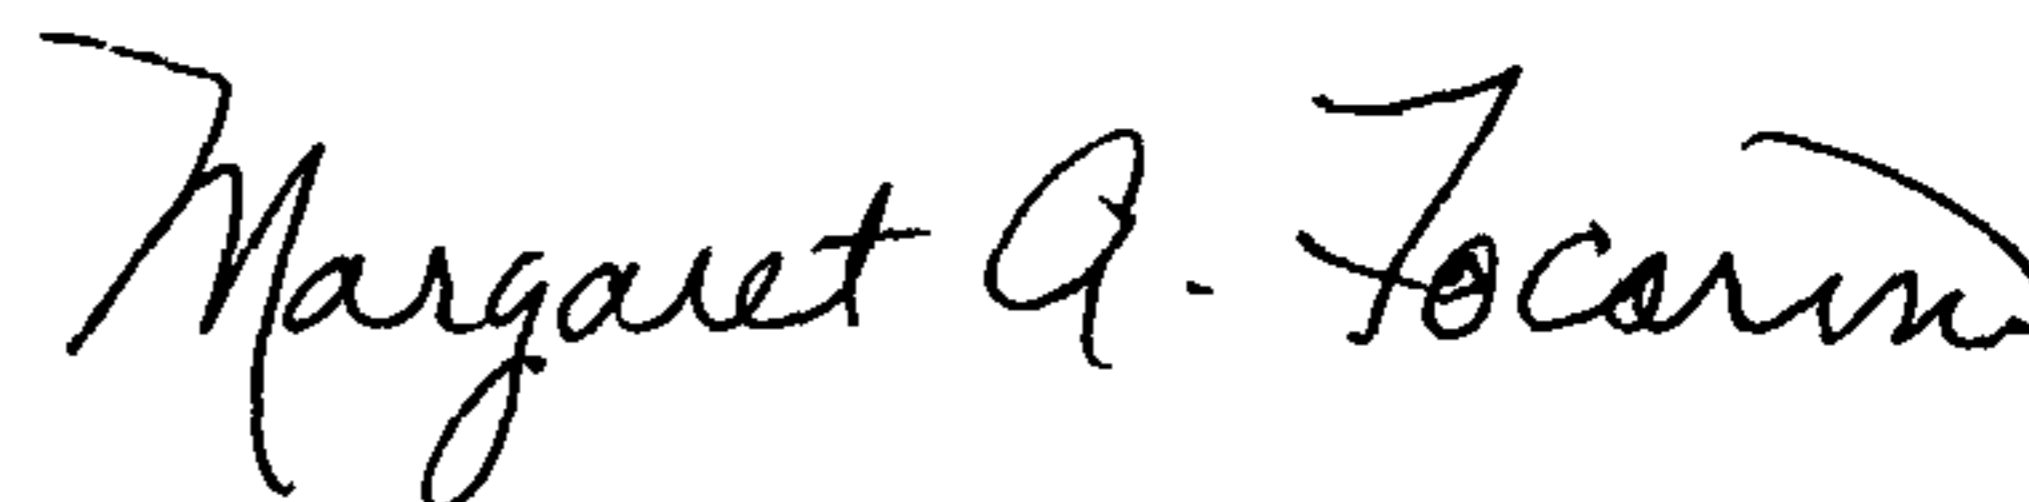

It is certified that error appears in the above-identified patent and that said Letters Patent is hereby corrected as shown below:

In the Claims:

Column 14, Line 1, Claim 30, "batter,/" should be --battery--.

Column 14, Line 3, Claim 31, "batter,/" should be --battery--.

Signed and Sealed this  
Seventeenth Day of December, 2013

Margaret A. Focarino  
*Commissioner for Patents of the United States Patent and Trademark Office*
