FIG. 1

FIG. 3

DUAL PANEL FABRICATION

Matter enclosed in heavy brackets [] appears in the original patent but forms no part of this reissue specification; matter printed in italics indicates the additions made by reissue; a claim printed with strikethrough indicates that the claim was canceled, disclaimed, or held invalid by a prior post-patent action or proceeding.

This application claims the benefit of U.S. Provisional Application No. 61/002,477; filed Dec. 9, 2007.

BACKGROUND OF THE INVENTION

The present invention relates generally to manufacturing processes, and, more specifically, to laminated panel fabrication.

The typical aircraft has a tubular fuselage and includes internal floors, ceilings, and partition walls. These components are manufactured from corresponding structural panels joined to a supporting structural frame.

A primary objective in manufacturing aircraft is minimizing the weight thereof while maintaining suitable strength for the expected loads experienced during flight operation. The various structural components of the aircraft therefore are specifically designed for the specific application in the aircraft for minimizing weight.

Accordingly, the construction panels used in the fabrication of aircraft have various configurations, dimensions, and material compositions as required for their use in the different parts of the aircraft. A common structural panel is a laminated assembly of outer plies or skins rigidly bonded to a middle or central structural core.

The core typically has a honeycomb configuration laminated to the thin solid skins typically using a thermally cured structural adhesive to form a unitary panel having high strength at correspondingly low weight.

The honeycomb core, the skins, and the adhesive bonding may have various material compositions as desired for the specific application in the aircraft. Common thereto, however, is the typical method of manufacturing or fabricating the structural panels irrespective of material composition.

More specifically, the structural panels are typically manufactured in larger rectangular flat sheets using a hydraulic panel press. The panel press typically includes multiple rectangular platens stacked vertically in the press, with adjacent platens defining corresponding openings or slots vertically therebetween.

The constituent parts of the panel are initially stacked together during assembly with the outer plies sandwiching therebetween the middle core, with corresponding preimpregnated (prepregs) adhesive layers being disposed therebetween. A single panel set is then positioned in each of the multiple slots in the press between corresponding platens.

The press is operated to compress together the stack of platens and panel sets therebetween under suitable pressure. The platens are suitably heated for in turn heating the panels sets and thermally curing the adhesive prepregs therebetween in a time-controlled cycle.

The platens are then cooled to correspondingly cool the thermally cured panels, which are then removed from the press in individual flat rectangular sheets.

The individual panel sheets are relatively large and flat and are manufactured with suitable dimensional tolerances which limit the amount of undesirable warping thereof. Little or no

warping is required to ensure that each panel remains flat across its entire rectangular configuration.

Such panel warping is minimized by ensuring during operation in a panel press that uniform heat is provided in each of the platens. The evenly heated platens compress the individual panels therebetween to correspondingly ensure that the individual panels themselves are also uniformly heated across their entire rectangular surface to ensure uniform adhesive bonding thereover in the time-limited cycle.

The fabricated laminated panels may then be used for subsequent manufacture of various components in the typical aircraft. From a single panel, for example, multiple parts having various configurations, profiles, and surface area may be suitably fabricated by precision outline cutting of the panel.

Accordingly, the flat laminated panels provide basic construction materials for subsequent manufacture in a typical aircraft, and are therefore manufactured in larger bulk quantities. To reduce the cost of manufacture of the panels themselves, various types of panel presses are utilized, commonly having multiple platens therein with corresponding slots therebetween. In this way, a single panel press may be used for simultaneously manufacturing multiple panels in a single operation over a specified curing cycle.

Typical panel presses may include five platens defining four corresponding slots for simultaneous manufacturing four individual laminated panels. Another conventional press includes seven platens defining six corresponding slots for simultaneous manufacture of six laminated panels. And, of course, single-slot presses are also available, with the number of platens and slots being as desired for differently sized presses.

Multiple panel presses are typically used in a factory for manufacturing many laminated panels in large bulk quantities, and increasing the number of manufactured panels requires more panel presses, with correspondingly higher factory and manufacturing costs therefor.

Accordingly, it is desired to provide an improved method of manufacturing laminated panels for increasing production rate thereof in otherwise conventional panel presses.

BRIEF DESCRIPTION OF THE INVENTION

A pair of laminated panels are simultaneously manufactured in a single panel press. A thermal band is stacked between two panel sets and then the two panel sets are simultaneously heated and compressed together in a common stack with the band, with the band being separately heated.

BRIEF DESCRIPTION OF THE DRAWINGS

The invention, in accordance with preferred and exemplary embodiments, together with further objects and advantages thereof, is more particularly described in the following detailed description taken in conjunction with the accompanying drawings in which:

FIG. 1 is a schematic representation of a panel press modified for doubling panel fabrication capacity thereof.

FIG. 2 is an exploded schematic representation of the manufacture of an exemplary pair of laminated panels in the press illustrated in FIG. 1, and taken generally along line 2-2.

FIG. 3 is a schematic elevational sectional view of the two exemplary panels being fabricated in FIG. 2 and taken generally along line 3-3.

DETAILED DESCRIPTION OF THE INVENTION

Illustrated schematically in FIG. 1 is a hydraulic panel press 10 having a suitable structural frame 12 for supporting its various components.

In particular, the press **10** includes a plurality of flat rectangular platens **14** suitably mounted or affixed in an adjustable vertical stack in the press frame **12**. Adjacent ones of the several platens **14** define vertically therebetween corresponding chambers or slots **16**. For example, five platens are illustrated in the exemplary press machine **10** and define four corresponding receptacle slots **16** therein

The panel press **10** further includes a structurally rigid anvil **18** in the form of a thick rectangular plate **18** fixedly joined to the frame **12** at the top thereof. At the opposite bottom of the frame **12**, a structurally rigid wedge **20** in the form of another thick rectangular plate is mounted in the frame atop a plurality of suitable piston actuators **22**, with four being illustrated for example.

The actuators **22** are in the exemplary form of hydraulic actuators suitably joined to a corresponding hydraulic pump **24** which may be manually or automatically controlled for pressurizing the individual actuators to lift the wedge **22** supported thereatop, with the wedge **22** being driven upwardly in elevation towards the top anvil **18** for compressing together the several platens, and the work products placed therebetween during operation.

The individual platens **14** are themselves rigid rectangular plates have suitable heat exchangers therein and suitably joined to one or more control valves **26**. The control valves **26** are in turn suitably joined to a boiler **28** which selectively circulates heated oil through the platens. Alternatively, a chiller **30** is also suitably joined to the control valves **26** for channeling cool oil through the several platens when required.

The panel press **10** described above is otherwise conventional and is commercially available from different manufacturers in different models with different platen capacities, with the four-slot model disclosed in FIG. **1** being representative. For example, one such five-platen panel press was commercially available from Columbia Machine and Engineering Corp of Columbia, Tenn. under model No. 11561.

The panel press is conventionally operated as described above in the Background section for manufacturing or fabricating laminated panels, with a single panel being fabricated in each of the four slots **16** in a single manufacturing process. That process typically requires several hours to complete for exemplary aircraft structural panels which require thermal curing of the adhesive prepregs therein followed by suitable cooling prior to removal of the individual panels from the press.

Accordingly, the conventional version of the panel press **10** illustrated in FIG. **1** may be conventionally operated for producing a maximum of four laminated panels from the corresponding four panel slots **16** thereof in each several-hour operating cycle.

However, it is desirable to increase the production capacity or rate of the otherwise conventional panel press **10** illustrated in FIG. **1**, and therefore that conventional press, as well as other conventional presses, may be suitably modified as described hereinbelow for increasing the production capacity thereof up to double, for example.

More specifically, the panel press **10** is specifically modified from its conventional configuration to include one or more thermal heating bands **32** corresponding to the multiple panel slots **16** found therein. Preferably, a single thermal band **32** is provided for each of the corresponding panel slots **16** in the thermal press, with four thermal bands being used for the four-slot press configuration.

The thermal band **32** has a corresponding power supply **34** suitably joined thereto which may be selectively operated to uniformly heat the thermal band **32** over its flat rectangular configuration.

In a preferred configuration, a plurality of suitable temperature sensors **36** in the exemplary form of conventional thermocouples are suitably joined or embedded in the several platens **14** and thermal bands **32** for measuring the local temperature thereof. As shown schematically in FIG. **1**, each platen **14** has an associated temperature sensor **36** suitably mounted therein for reading its operating temperature, with each of the four thermal bands **32** also having a corresponding temperature sensor **36** for reading the operating temperature thereof as well.

A suitable temperature controller **38** is operatively joined to the full complement of temperature sensors **36** and is also joined to the power supply **34** for feedback control thereof.

The temperature controller **38** may have any conventional configuration, such as a programmable line controller with multiple electrical input and output terminals for attaching the corresponding electrical leads from the many temperature sensors **36**, as well as the power supply **34**. One exemplary controller is commercially available in a multichannel configuration as model 1767 MicroLogix 1200, manufactured by the Allen Bradley Company, of Milwaukee, Wis.

During operation, the temperature controller **38** may be used to monitor transient and steady state temperatures of the several platens **14** and thermal bands **32** for suitably controlling operation of the increased capacity panel fabrication process.

More specifically, the improved panel press **10** as modified above may be used for increasing capacity, and doubling capacity for example, of panel production therefrom. In particular, a pair of laminated panels **40** may be fabricated in each of the corresponding panel slots **16** of the panel press **10**, instead of a single laminated panel therein.

As additionally shown in FIG. **2**, each fabricated panel **40** is initially formed of a corresponding stack or set **42** of panel laminates or layers in vertical stack thereof. Two laminate sets **42** are arranged in a common vertical stack or group **44** having a corresponding thermal band **32** disposed vertically therebetween in the middle thereof and extending horizontally in rectangular configuration.

The dual panel group **44** is then loaded into the panel press **10** and simultaneously heated and compressed together while the thermal band **32** is separately heated in the middle thereof.

In this way, the corresponding laminate sets **42** are separately heated on opposite sides thereof in each group **44** to ensure uniform heating thereof for correspondingly ensuring proper thermal curing of the prepreg adhesives therein for minimizing or eliminating undesirable warping of the finally cured panels.

In a previous development test for increasing production capacity of panel presses, two panel sets were stacked together without the intervening thermal band therebetween and cycled in the press. The resulting cured panels experienced undesirable warping thereof due to the inability to achieve even or uniform temperature throughout the panel sets during the cure cycle.

A single panel set has a corresponding thickness and may be uniformly heated throughout from the heat provided in the two heated platens on opposite sides thereof. However, simply stacking together two panel sets between the same two heated platens doubles the collective thickness thereof and correspondingly reduces the heat transfer rate therethrough.

The thermal curing process must be accomplished over a limited time duration for properly curing the adhesive. And

5

the double thickness of two panel sets significantly reduces heat transfer and prevents uniform curing of the adhesive in the allotted cycle time.

However, by specifically introducing the middle thermal band **32** in the stack of two panel sets **42**, an additional source of heat may therefore be provided between the two sets so that each panel set is again heated from both its opposite sides within the single panel slot **16** in the panel press between only two opposite platens **14**.

Accordingly, without the introduction of expensive additional platens in the conventional panel press, the relatively simple thermal band **32** may instead be introduced for doubling production capacity of the panel press with minimal modifications thereof, at substantially reduced expense, and eliminating the need for purchasing additional panel presses for increasing production capability.

Accordingly, the laminated panels **40** may be made in a new process in the modified panel press **10** by initially separately assembling or stacking the two sets **42** of panel laminates in any desired configuration, dimensions, and material composition.

The two stacked sets **42** are then stacked together in a common stack on opposite sides of the thermal band **32** in the collective dual panel group **44**. The dual panel groups **44** are then loaded into the corresponding platen slots **16**.

The panel press **10** is then conventionally operated for compressing together under pressure *P* the dual panel group **44** in each of the corresponding panel slots **16** between corresponding pairs of the heated platens **14** using the hydraulic actuators **22**.

The boiler **28** is then used for suitably circulating hot heated oil through the several platens **14** which are then uniformly heated over their entire rectangular surface area to correspondingly heat each panel group **44** from opposite top and bottom sides.

Correspondingly, the thermal band **32** in each panel group **44** is separately heated to correspondingly heat the two panel sets **42** in each panel group **44** from the middle thereof across their entire rectangular surface area, and thereby thermally bond together the panel laminates in each of the two sets **42**.

In this way, each dual panel group **44** is heated by the platens on the opposite top and bottom surfaces thereof as well as being heated by the thermal band in the middle thereof for uniformly heating both panel sets **42** across their rectangular surface area on opposite sides thereof.

Each dual panel group **44** is therefore initially placed in a single common slot **16** between locally top and bottom platens **14**. The two platens **14** are then compressed together between the anvil **18** and wedge **20** by pressurizing the actuators **22**. The platens in turn compress each dual panel group **44** which are simultaneously heated by the heated platens **14** themselves which in turn heats the two panel sets **42** and thermally bonds together the panel laminates in each of the two sets to correspondingly form the two cured laminated panels **40** from each of the several panel slots **16**.

The compressing and heating cycle may take several hours depending upon the specific material compositions of the panel laminates and adhesive therein as required for proper thermal curing thereof, following which the control valves **26** are suitably operated for circulating relatively cool oil through the several platens cooled by the chiller **30** for promptly cooling the thermally cured laminated panels **40** themselves.

The dual panel group **44** in each of the panel slots **16** is then removed from the panel press and disassembled for liberating or removing each of the two cured panels **40** from the group

6

assembly and the corresponding thermal band **32**, which may again be used in subsequent production cycles.

A particular advantage of the simple modification of the otherwise conventional panel press **10** illustrated in FIG. **1** is the ability to simultaneously make multiple pairs of the laminated panels **40** in corresponding slots **16** between corresponding platens **14** in the single or common panel press **10** and in a single production cycle. By introducing a single thermal band **32** in each of the four panel slots **16**, the production capability of the otherwise conventional panel press **10** may be readily doubled.

As shown schematically in FIG. **1**, multiple groups **44**, for example four, of the two panel sets **42** with corresponding thermal bands **32** may be separately assembled or stacked. The so assembled groups are then suitably placed in the four corresponding slots **16** of the press between corresponding top and bottom ones of the plurality of stacked platens **14**. The stack of platens **14** is then compressed together by supplying pressure to the actuators **22** to simultaneously compress the multiple panel groups **44**.

The multiple platens **14** are then simultaneously heated, and the multiple thermal bands **32** are simultaneously powered to collectively heat the constituent panel laminates in each of the two panel sets **42** in each of the multiple panel groups **44** in each of the four panels slots **16** to simultaneously form multiple laminated panels **40**. In the four slot panel press **10** illustrated in FIG. **1**, the panel production capacity is doubled from four to eight panels for each production cycle.

As shown schematically in both FIGS. **1** and **2**, the temperature controller **38** is operatively joined to at least one of the platens **14** for each of the corresponding panel slots, and is also operatively joined to each of the several thermal bands **32**.

The temperature controller **38** is also operatively joined to the power supply **34** and is suitably configured in software to power the thermal band **32** to match the measured temperature thereof to the measured temperature of at least one of the two platens **14** bounding each panel group **44** in a corresponding panel slot **16**.

For example, the temperature controller **38** is suitably configured to measure the operating temperature of the heated platens **14** at each of the multiple panel groups **44** by reading the corresponding temperature sensor **36** for the locally top platen and its temperature *T1* or the locally bottom platen and its temperature *T3*, or both.

The controller **38** is also configured to measure the operating temperature *T2* of each of the thermal bands inside each of the multiple panel groups **44**.

And then, the controller is configured to power each of the thermal bands **32** by suitably cycling on or off the corresponding power supply **34** to separately match the measured temperature *T2* thereof to the measured temperature *T1* or *T3* of the corresponding top or bottom platens **13**.

A conventional feedback loop may be programmed *in* software to power the thermal bands so that as the temperature of the platens **14** increases during the production cycle, the corresponding temperature of the thermal bands may be increased to follow and match the temperature of the bounding platens within suitably small temperature tolerances, such as plus or minus 2 degrees (F.).

In other words, each thermal band **32** is independently powered to match or equal the measured temperature of the bounding platens **14** whose temperatures *T1* and *T3* are normally equal to each other due to the common circulation of the heated oil from the common boiler **28**.

In the preferred configuration illustrated in FIG. **2**, the thermal band **32** is in the form of a thin, rectangular electrical

blanket having a temperature sensor thermocouple **36** suitably embedded therein, and operatively joined by an electrical lead to the temperature controller **38**. Any suitable electrical blanket may be used as required for the particular panel manufacturing process and may be commercially purchased.

For example, an industrial electrical blanket may be used with a heating capability of about one watt per square inch over the rectangular surface area of the blanket and formed of a suitably flexible fabric weave with electrical heating wire grids laminated therein.

Suitable industrial heating blankets include a grid of wound resistance wire vulcanized between two layers of fiberglass reinforced silicone rubber, and may be commercially obtained from Heatcon Inc., Seattle, Wash. Either a standard industrial heating blanket may be used, or they may be custom made to larger size as required.

The thermal bands **32** require suitable configurations for withstanding the corresponding compression pressures P during operation, which may be about 35 psi in one embodiment, and may be as high as required for correspondingly producing various panels.

In one configuration, the platens **14** are conventionally heated to about 200 degrees F., with the thermal band **32** being suitably configured for matching that 200 degree F. capability, with suitable power or wattage for matching the transient rise of temperature of the platens for required production cycles.

Although the thermal band **32** is described in the preferred configuration of an industrial electrical heating blanket, other configurations thereof are possible for suitably internally heating the dual panel groups **44** as described above.

The various temperature sensors **36** illustrated schematically in FIGS. **1** and **2** may have any conventional configuration, such as typical thermocouples, with each of the several platens **14** preferably including a corresponding temperature sensor **36** suitably mounted therein and operatively joined by electrical leads to the temperature controller **38**.

During operation, the platens **14** and electrical blankets **32** are separately heated, with the electrical blanket **32** being powered by the power supply **34** for being heated to follow and match equally the heating of the platens **14** in response to the corresponding temperatures T_1 , T_2 , T_3 measured from the temperature sensors **36**.

In the preferred embodiment illustrated in FIGS. **1** and **2**, the two panel sets **42** are preferably identical to each other in configuration, materials, plies, and dimensions within correspondingly small tolerances for making correspondingly identical laminated panels **40** within correspondingly small manufacturing tolerances.

FIG. **3** illustrates schematically an exemplary configuration of each of the two panel sets **42** which correspondingly form the resulting structural panels **40**. As indicated above, each of the panels **40** has an exemplary flat rectangular configuration of 4×8 or 4×12 feet in dimensions (122×244 or 122×366 cm), and is formed of suitable structural laminations or plies.

The platens **14** are suitably larger, such as 5×12 feet (152×366 cm), and about two inches (51 cm) thick for structural rigidity.

For example, each of the panel sets **42** includes a structural honeycomb core [one] **1** laminated by corresponding adhesive plies **2** to corresponding outer plies or skins **3**.

Each panel set **42** therefore has five plies in which the two adhesive plies **2** are thermally cured during the production process to form the resulting rigid panel **40**.

The honeycomb core **1** may be formed of suitable metal, like aluminum, or may be otherwise manufactured from vari-

ous synthetic or composite materials as desired. The honeycomb cells preferably extend perpendicularly between the opposite top and bottom skin plies **3** of the panel for maximizing strength and structural rigidity.

Correspondingly, the outer skins **3** may be formed of a suitable metal like thin sheet metal aluminum, or other suitable synthetic or composite materials as desired.

The adhesive plies **2** may be suitably selected for specific panel configurations and are typically pre-impregnated (preg) adhesive plies which are activated and cured by applying heat thereto.

A specific configuration of the laminate sets **42** and resulting panels **40** may be chosen as desired for specific applications, but share a common fabrication process thereof in the panel press disclosed above as modified for doubling production capacity.

FIG. **3** further illustrates the use of conventional protective liners **4,5** disposed directly on both opposite sides of each thermal band **32** and directly inside or along each of the corresponding platens **14** to sandwich together the two panel sets **42**. Each of the protective liners preferably includes one layer or ply of conventional release paper **4** directly adjoining the corresponding panel skins **3**, followed by another ply or layer of conventional chip board **5** bounding the release paper **4** in turn.

Each dual panel group **44** further includes corresponding caul sheets **6** disposed on opposite sides thereof in direct opposition with the corresponding top and bottom platens **14**. The caul sheets are conventional and ensure uniform distribution of the bonding pressure P from the opposite platens **14** into the common stack of dual laminate sets **42** during the production cycle.

Each of the several platens **14** best illustrated in FIG. **2** is a flat rectangular plate sufficiently large to compress together the correspondingly flat and rectangular panel laminates **1-3**.

Correspondingly, each of the thermal bands **32** is flexible and rectangular with sufficient size to match the rectangular surface area of the corresponding laminate sets **42** as well as the protective liners **4,5**. For example, each band **32** may be 4 to 5 feet (122 to 152 cm) wide, and 8 to 12 feet (244 to 366 cm) long, and less than an inch (2.5 cm) thick.

In this way, each thermal band **32** is itself heated uniformly by its corresponding power supply **34** and in turn uniformly heats the two panel sets **42** at the middle junction thereof in the common vertical stack to correspondingly produce the two flat rectangular panels **40** illustrated in FIG. **3**. And, panel warpage may be eliminated or reduced to less than about one-half percent deflection perpendicular to the panel over its length.

With the relatively simple introduction of the several thermal bands **32** disclosed above, the otherwise conventional panel press **10** may be modified for doubling its production capacity without compromising the thermal curing process. The double thickness of the dual laminate sets **42** is effectively accommodated by the introduction of the intermediate thermal band **32** to ensure uniform heating of each panel set **42** from both its opposite sides with substantially equal thermal response time for simultaneously producing two panels in each panel slot in substantially the same cycle time as that previously required for a single panel in a single panel slot.

While there have been described herein what are considered to be preferred and exemplary embodiments of the present invention, other modifications of the invention shall be apparent to those skilled in the art from the teachings herein, and it is, therefore, desired to be secured in the appended claims all such modifications as fall within the true spirit and scope of the invention.

Accordingly, what is desired to be secured by Letters Patent of the United States is the invention as defined and differentiated in the following claims in which I claim:

1. A method of making a laminated panel in a panel press [having adjacent platens], comprising:
 - compressing together [between said adjacent platens] *in said panel press* two sets of panel laminates on opposite sides of a thermal band; [and] *each of said panel sets comprising a honeycomb core laminated between top and bottom skins, and an adhesive ply laminated between said core and skins;*
 - heating said two sets of panel laminates along opposite top and bottom sides thereof;*
 - [circulating heating fluid internally through said platens and separately] heating said thermal band to *internally* heat said two panel sets and thermally bond together said panel laminates in each of said two panel sets to double production capability of said panel press;
 - measuring temperature of said internal heating; and powering said thermal band in response to said measured temperature of said internal heating.*
2. A method according to claim 1 further comprising: assembling said two sets of panel laminates; stacking together said two panel sets on opposite sides of said thermal band in a collective dual panel group *having said opposite top and bottom sides;* and compressing together said dual panel group [between said adjacent platens] *in said panel press.*
3. A method according to claim 2 further comprising: placing said dual panel group in a common slot between top and bottom platens inside said panel press; compressing together said platens to compress said dual panel group; and circulating heating fluid through said platens to heat [correspondingly] *said* opposite top and bottom sides of said dual panel group, and separately heating said thermal band to internally heat said dual panel group and thermally bond together said panel laminates in each of said two panel sets to correspondingly form two laminated panels.
4. A method according to claim 3 further comprising: circulating cooling fluid through said platens to cool said laminated panels; and removing said two panels from said platens and thermal band.
5. A method according to claim 3 further comprising: measuring temperature of one of said heated platens; measuring temperature of said thermal band; and powering said thermal band to match said measured temperature thereof to said measured temperature of said one platen.
6. A method according to claim 3 further comprising: assembling multiple groups of said two panel sets with corresponding thermal bands; placing said multiple groups in corresponding slots between a plurality of stacked platens; compressing together said stack of platens to simultaneously compress said multiple groups; and heating said stacked platens and corresponding thermal bands to collectively heat said panel laminates in each of said two panel sets in each of said multiple groups to simultaneously form multiple laminated panels.
7. A method according to claim 6 further comprising: measuring temperature of said heated platens at each of said multiple groups; measuring temperature of said thermal bands in each of said multiple groups; and

powering each of said thermal bands to match said measured temperature thereof to said measured temperature of corresponding platens.

8. A method according to claim 3 wherein: said platens are mounted in a frame inside said panel press; said panel press further includes an anvil fixed to said frame and an opposite wedge movably driven by piston actuators; and said platens and dual panel group are disposed between said anvil and wedge, with said wedge being driven by said actuators for compression thereof.
9. A method according to claim 8 wherein: said panel press further includes a temperature controller operatively joined to one of said platens and to said thermal band; and said temperature controller is configured to power said thermal band to match temperature thereof to temperature of said one platen.
10. A method according to claim 9 wherein: said thermal band comprises an electrical blanket having a temperature sensor embedded therein, and operatively joined to said controller; said one platen includes another temperature sensor mounted therein, and operatively joined to said controller; and said platens and electrical blanket are separately heated, with said electrical blanket being heated to follow heating of said platens in response to temperatures measured from said temperature sensors.
11. A method according to claim [3] 2 wherein said two panel sets are identical to each other for making correspondingly identical laminated panels.
- [12. A method according to claim 3 wherein each of said panel sets comprises a honeycomb core laminated between top and bottom skins, and an adhesive ply laminated between said core and skins.]
13. A method according to claim [12] 2 wherein said dual panel group further comprises a protective liner disposed on both sides of said thermal band and [inside each of said platens] *directly adjoining corresponding panel skins.*
14. A method according to claim 13 wherein each of said protective liners comprises layers of release paper and chip board.
15. A method according to claim 13 wherein said dual panel group further comprises corresponding caul sheets disposed on opposite sides thereof [in opposition with said top and bottom platens].
16. A method according to claim 3 wherein: said top and bottom platens comprise flat plates; said panel laminates are flat and rectangular; and said thermal band is flexible and rectangular, and heated uniformly to uniformly heat said two panels sets to produce two flat rectangular panels.
17. A method of making a pair of laminated panels comprising: simultaneously heating and compressing together in a [single slot between adjacent platens in a] panel press two sets of panel laminates in a common stack having a separately heated thermal band in the middle thereof and [heating fluid circulating internally through said platens] *wherein each of said panel sets comprises a honeycomb core laminated by an adhesive ply between top and bottom skins, and said thermal band comprises an electrical blanket having a temperature sensor embedded therein and operatively joined to a temperature controller, and powering said thermal band in response to measured temperature of said thermal band.*

11

18. A method according to claim 17 further comprising simultaneously making multiple pairs of said laminated panels [in corresponding slots between] by introducing in the middle thereof corresponding ones of said separately heated thermal bands instead of corresponding platens in said panel press.

19. A method according to claim 18 further comprising modifying said panel press to include:

a plurality of said thermal bands for said corresponding [slots] common stacks therein;

a plurality of temperature sensors for said [platens and] thermal bands to measure temperature thereof; and

[a] said temperature controller is configured to power said thermal bands [for following] in response to measured temperature [of said platens] thereof.

20. A panel press for manufacturing multiple laminated panels, said press comprising:

[a plurality of platens mounted in a frame, and defining corresponding slots therebetween;]

an anvil fixed to a frame, and an opposite wedge movably driven by piston actuators for compressing multiple groups of panel laminates to correspondingly form said multiple laminated panels;

a plurality of thermal bands corresponding with said [slots] multiple laminate groups, with each group comprising two sets of panel laminates on opposite sides of a corresponding thermal band, and each of said panel sets comprises a honeycomb core laminated between top and bottom skins, and an adhesive ply laminated between said core and skins;

a plurality of temperature sensors mounted in said [platens and in said] thermal bands for measuring temperature thereof; and

a temperature controller to power said thermal bands for [following] controlling measured temperature [of said platens] thereof.

21. A method according to claim 2 further comprising: assembling multiple groups of said two panel sets with corresponding thermal bands;

placing said multiple groups in a vertical stack in said panel press;

simultaneously compressing together in said panel press said stack of multiple groups; and

heating each of said dual panel groups along said top and bottom sides thereof and correspondingly powering said thermal bands to internally heat said panel laminates in

12

each of said two panel sets in each of said multiple groups to simultaneously form multiple laminated panels.

22. A method according to claim 21 wherein:

said panel press further includes a temperature controller operatively joined to said thermal bands; and

said temperature controller is configured to power said thermal bands to match said internal heating of said two panel sets with measured temperature of corresponding heating of said top and bottom sides in each of said multiple groups.

23. A method according to claim 22 wherein:

each of said thermal bands comprises an electrical blanket having a temperature sensor embedded therein for measuring said temperature of internal heating, and said sensors are operatively joined to said temperature controller for powering said electrical blankets in feedback response to said measured temperature of internal heating.

24. A method according to claim 2 wherein:

said panel laminates are flat and rectangular; and said thermal band is flexible and rectangular, and heated uniformly to uniformly heat said two panels sets to produce two flat rectangular panels.

25. A method of making a laminated panel in a panel press having an anvil fixed to a frame and an opposite wedge movably driven by piston actuators, said method comprising: assembling multiple sets of panel laminates;

each of said panel sets including a honeycomb core laminated between top and bottom skins, and an adhesive ply laminated between said core and skins;

stacking together said multiple panel sets on opposite sides of corresponding thermal bands in collective dual panel groups having opposite top and bottom sides in each group, with a corresponding thermal band in the middle thereof;

compressing together in said panel press between said anvil and wedge said multiple panel groups;

heating said multiple panel groups along said top and bottom sides thereof;

heating said thermal bands to internally heat said multiple panel groups;

measuring temperature of said thermal band in each panel group; and

powering said thermal bands in response to said measured temperatures of said thermal bands for thermally bonding together said panel laminates in each panel group.
