(57) **ABSTRACT**

A driving method of a light-emitting diode (LED) adapted to a driving apparatus is provided. The driving method includes detecting whether the driving apparatus performs dimming, and if the driving apparatus performs dimming, determining whether a predetermined requirement for dimming control is met or not. When the predetermined requirement for dimming control is not met, respective current magnitudes of a plurality of driving currents are regulated, and each of the driving currents is output for a full time of a period. Conversely, when the predetermined requirement for dimming control is met, each of the driving currents is output for a partial time of a period.

The entirety of each of the above-mentioned patent applications is hereby incorporated by reference herein and made a part of this specification.

BACKGROUND OF THE INVENTION

1. Field of the Invention

The present invention relates to a driving method. More particularly, the present invention relates to a driving apparatus of a light-emitting diode and a driving method thereof.

2. Description of Related Art

Light emitting diodes (LEDs) have advantages of small size, power-saving and high durability, and as fabrication processes thereof become mature, price of the LEDs decreases. Therefore, it is popular to use the LEDs as light source products. Moreover, since the LED has features of low-operating voltage (only 1.5-3V), initiative light-emitting, and having a certain brightness, wherein the brightness can be adjusted by voltage or current, and has features of impact resistance, anti-vibration and long lifespan (100,000 hours), the LED is widely used to various terminal equipments, such as vehicle headlamps, traffic lights, text displays, billboards and large screen video displays, and domains such as general level architectural lighting and liquid crystal display (LCD) backlight, etc.

Regarding a driving circuit of the LED, a commonly used dimming method thereof is to regulate a duty cycle of a pulse according to a pulse-width modulation (PWM) technique, so as to regulate an equivalent current output to the LED by an output stage to adjust a brightness of the LED. However, when the PWM technique is used for dimming, a current switching operation of the output stage is the same as that of a switch. The current switching operation lead to a great load variation of a voltage of the output stage, so that the voltage may have an excessive ripple. Meanwhile, the excessive ripple can cause a great magnetic field variation of an inductor in the circuit, and a capacitor in the circuit can be sharply vibrated to generate a shape-changing due to an excessive transient voltage variation, so that an audio noise is generated.

FIG. **1**A is a system schematic diagram illustrating a conventional driving circuit of an LED. Referring to FIG. **1**A, the driving circuit **100** includes a voltage converter **110**, a conversion loop controller **120**, an amplifier **130**, a voltage selector **140** and a current driving unit **150** formed by a plurality of current driving devices. The voltage converter **110** receives a power voltage V_{DD}, and generates an operating voltage V_{CC} with a level different to that of the power voltage V_{DD} according to an output of the conversion loop controller **120**. A positive input terminal of the amplifier **130** receives a reference voltage Vref, and a negative input terminal thereof receives an output voltage of the voltage selector **140**, so that the amplifier **130** accordingly outputs a voltage to control the conversion loop controller **120**, wherein the reference voltage Vref is a fixed value. The voltage selector **140** selects and outputs a voltage of a negative terminal of one of LED strings **50_1-50**_n. Positive terminals of the LED strings **50_1-50**_n receive the operating voltage V_{CC}, and the negative terminals of the LED strings **50_1-50**_n are respectively coupled to the current driving unit **150** through switches S**1**-Sn. The LED strings **50_1-50**_n are driven by load currents and the switches are switched according to a dimming signal, so as to implement a dimming operation.

FIG. **1**B is a timing diagram of the driving currents of FIG. **1**A. Referring to FIG. **1**A and FIG. **1**B, in the LED driving circuit **100**, the PWM technique is generally used to regulate a time t_1 for supplying the load currents so as to adjust the brightness of the LED. In other words, in a fixed period T, the longer the time t_1 is, the higher the brightness of the LED is. Conversely, the shorter the time t_1 is, the lower the brightness of the LED is. However, when the PWM technique is used for dimming, switching operations of the switches S**1**-Sn lead to a variation of the load currents and the variation of the load currents can lead to a great load variation of the operating voltage V_{CC}, so that the operating voltage V_{CC} output by the voltage converter **110** may have an excessive ripple. Meanwhile, an input current of the voltage converter **100** may also have a great transient variation, which may not only cause a great magnetic field variation of an inductor in the voltage converter **100**, but also a regulation capacitor in the voltage converter **100** can be sharply vibrated to generate a shape-changing due to an excessive transient voltage variation, so that the audio noise is generated. Moreover, regarding the driving circuit **100**, during the dimming, the switches S**1**-Sn are simultaneously switched to switch the load currents i_1-i_n, though the current switching operation can cause a severe electromagnetic interference (EMI).

SUMMARY OF THE INVENTION

The present invention is directed to a driving apparatus of a light-emitting diode (LED) and a driving method thereof, which can suppress an audio noise and an electromagnetic interference (EMI).

The present invention provides a driving method of an LED, which is adapted to a driving apparatus. The driving method includes following steps. First, whether the driving apparatus performs dimming is detected. Next, when the driving apparatus is detected to perform dimming, determining whether a predetermined requirement for dimming control is met or not. When the predetermined requirement for dimming control is not met, respective current magnitudes of a plurality of driving currents are regulated, and each of the driving currents is output for a full time of a period. When the predetermined requirement for dimming control is met, each of the driving currents is output for a partial time of a period.

The present invention provides a driving method of an LED, which is adapted to a driving apparatus. The driving apparatus receives a dimming signal. The driving method includes following steps. First, it is detected whether the driving apparatus performs dimming. Next, when the driving apparatus is detected to perform the dimming, regulating at least one of a respective current magnitude and a respective outputting time of each of a plurality of driving currents in a period according to a duty cycle of the dimming signal, such that a sum of the driving currents calculated for a period is substantially proportional to the duty cycle of the dimming signal

The present invention provides a driving circuit for driving a plurality of LEDs. The driving circuit includes a plurality of switches, a dimming detector and a current control unit. The switches are respectively coupled to the LEDs. The dimming detector receives a dimming signal, and detects whether the driving apparatus performs dimming according to the dimming signal, so as to output a dimming mode signal according to the dimming signal. The current control unit outputs a plurality of control signals according to the dimming mode signal and the dimming signal, and the control signals respectively control conducting states of the switches.

The present invention provides an electronic device that includes said driving circuit and a plurality of LEDs coupled to and driven by the driving circuit.

According to the driving apparatus of the LED of the present invention and the driving method thereof, when the driving apparatus performs the dimming and the duty cycle of the dimming signal is smaller than the predetermined value, the outputting time of the driving currents are equally allotted in a period, and the current magnitude of each of the driving currents is correspondingly regulated. When the driving apparatus performs the dimming and the duty cycle of the dimming signal is equal to or greater than the predetermined value, the driving currents are simultaneously output in the period, and the current magnitude of each of the driving currents is regulated according to the dimming signal. By such means, the audio noise and the EMI caused by excessive variation of a sum of the driving currents are suppressed.

In order to make the aforementioned and other features and advantages of the present invention comprehensible, several exemplary embodiments accompanied with figures are described in detail below.

BRIEF DESCRIPTION OF THE DRAWINGS

The accompanying drawings are included to provide a further understanding of the invention, and are incorporated in and constitute a part of this specification. The drawings illustrate embodiments of the invention and, together with the description, serve to explain the principles of the invention.

FIG. **1**A is a system schematic diagram illustrating a conventional driving circuit of an LED.

FIG. **1**B is a timing diagram of driving currents of FIG. **1**A.

FIG. **2**A is a schematic diagram illustrating a driving circuit according to an embodiment of the present invention.

FIG. **2**B is a current waveform diagram of LED strings of FIG. **2**A.

FIG. **2**C is another current waveform diagram of LED strings of FIG. **2**A.

FIG. **2**D is a waveform diagram of a driving apparatus and LED strings of FIG. **2**A.

FIG. **2**E is a schematic diagram illustrating a current control unit and a dimming detector of FIG. **2**A.

FIG. **2**F is a schematic diagram illustrating a duty cycle to voltage converter of FIG. **2**E.

FIG. **2**G is another schematic diagram illustrating a duty cycle to voltage converter of FIG. **2**E.

FIG. **2**H is another schematic diagram illustrating a current control unit and a dimming detector of FIG. **2**A.

FIG. **2**I is still another schematic diagram illustrating a current control unit and a dimming detector of FIG. **2**A.

FIG. **3**A is a flowchart illustrating a driving method according to an embodiment of the present invention.

FIG. **3**B is a flowchart illustrating a driving method according to another embodiment of the present invention.

DESCRIPTION OF THE EMBODIMENTS

Reference will now be made in detail to the present preferred embodiments of the invention, examples of which are illustrated in the accompanying drawings. Wherever possible, the same reference numbers are used in the drawings and the description to refer to the same or like parts.

FIG. **2**A is a schematic diagram illustrating a driving circuit according to an embodiment of the present invention. Referring to FIG. **2**A, the driving circuit **200** includes a voltage converter **210**, a conversion loop controller **220**, an amplifier **230**, a voltage selector **240**, a current driving unit **250**, a dimming detector **260**, a current control unit **270** and switches SW**1**-SWn. The dimming detector **260** receives a dimming signal Sdim, and detects whether the driving apparatus **200** performs dimming according to the dimming signal Sdim, so as to output a dimming mode signal Smod. The current control unit **270** outputs a plurality of control signals Sco**1** and a control voltage Vco**1** according to the dimming mode signal Smod and the dimming signal Sdim. The control signals Sco**1** respectively control a conducting state of each of the switches SW**1**-SWn, and the control voltage Vco**1** controls the current driving unit **250** to regulate current magnitudes of driving currents I_1-I_n.

The voltage converter **210** receives a power voltage V_{DD}, and generates an operating voltage V_{CC} with a level different to that of the power voltage V_{DD} according to an adjusting signal output from the conversion loop controller **220**. The conversion loop controller **220** generates the adjusting signal according to a received voltage. A positive input terminal of the amplifier **230** receives a reference voltage V_R, and a negative input terminal thereof receives a voltage output from the voltage selector **240**, so that the amplifier **230** accordingly outputs a voltage to the conversion loop controller **220**, wherein the reference voltage V_R can be a fixed value. The voltage selector **240** selects and outputs a voltage of a negative terminal of one of light-emitting diode (LED) strings **50_1-50_**n. Positive terminals of the LED strings **50_1-50_**n receive the operating voltage V_{CC}, and the negative terminals of the LED strings **50_1-50_**n are respectively coupled to the current driving unit **250** through the switches SW**1**-SWn. The LED strings **50_1-50_**n are driven by the driving currents i_1-i_n.

When a duty cycle of the dimming signal Sdim is 100%, it represents that the driving apparatus does not perform the dimming. Now, the current control unit **270** generates the control signals Sco**1** according to the dimming mode signal Smod, so as to control the switches to be simultaneously conducted in a period, and control the current driving unit **250** to regulate a current magnitude D of each of the driving currents I_1-I_n to a current upper limit according to the control voltage Vco**1**. When the duty cycle of the dimming signal Sdim is not 100%, it represents that the driving apparatus performs the dimming. Now, the current control unit **270** also generates the control signals Sco**1** according to the dimming mode signal Smod, so as to control conducting time of the switches SW**1**-SWn to be equivalent in a period, and control the current driving unit **250** to regulate the current magnitudes of the driving currents I_1-I_n according to the control voltage Vco**1**, wherein the current driving unit **250** can be formed by a plurality of voltage-controlled current sources, so as to simultaneously regulate the current magnitudes of the driving currents I_1-I_n according to the control voltage Vco**1**. It should be noticed that a relationship between the duty cycle of the dimming signal Sdim and whether the driving apparatus **200** performs the dimming is only used as an example, which can be modified according to an actual requirement.

The dimming operation of the driving apparatus **200** is further described below. FIG. **2**B is a current waveform diagram of the LED strings of FIG. **2**A. Referring to FIG. **2**A and FIG. **2**B, when the driving apparatus **200** performs the dimming and the duty cycle of the dimming signal Sdim is greater than or equal to a predetermined value, the current control unit **270** generates a plurality of the control signals Sco**1** and the control voltage Vco**1** according to the dimming mode signal Smod and the dimming signal Sdim. The control signals Sco**1** control the switches SW**1**-SWn to be simultaneously conducted in a period T, so as to simultaneously provide the driving currents I_1-I_n to the LED strings **50_1**-**50**_n. The currents on the LED strings **50_1**-**50**_n present a direct current (DC) state rather than a pulse state due to that the switches SW**1**-SWn are maintained conducted. Moreover, the current driving unit **250** regulates the current magnitude D of each of the driving currents I_1-I_n according to the control voltage Vco**1**, wherein the current magnitude D relates to the duty cycle of the dimming signal Sdim, for example, if the duty cycle is 1/8, the current magnitude D is equal to 1/8 of the current upper limit. The predetermined value can be a ratio between the period T and a number n of the driving currents I_1-I_n, for example, if the number n of the driving currents is 8, the predetermined value is then 1/8 of the period (i.e. T/8).

FIG. **2**C is another current waveform diagram of the LED strings of FIG. **2**A. Referring to FIG. **2**A and FIG. **2**C, when the driving apparatus **200** performs the dimming and the duty cycle of the dimming signal Sdim is smaller than the predetermined value, the current control unit **270** also generates a plurality of the control signals Sco**1** and the control voltage Vco**1** according to the dimming mode signal Smod and the dimming signal Sdim. The control signals Sco**1** control conducting time t_2 of each of the switches SW**1**-SWn to be equivalent in the period T, so as to respectively output the driving currents I_1-I_n to the LED strings **50_1**-**50**_n. For example, if a number of the switches is 8, the conducting time t_2 is then 1/8 of the period T. The current driving unit **250** regulates the current magnitude D of each of the driving currents according to the control voltage Vco**1**, wherein the current magnitude D relates to the duty cycle of the dimming signal Sdim and the predetermined value, for example, if the duty cycle is 1/16, the current magnitude D is equal to 1/2 of the current upper limit, i.e. equal to the duty cycle (i.e. 1/16) divided by the predetermined value (i.e. 1/8) times the current upper limit The driving currents I_1-I_n can be sequentially output in turn or can be output in turn according to a random sequence.

Accordingly, regardless of the switches SW**1**-SWn being simultaneously or respectively conducted during the period T according to the duty cycle of the dimming signal Sdim, a sum of the driving currents I_1-I_n is approximately maintained to a fixed value, which can greatly reduce or even eliminate a load variation of the operating voltage V_{CC}, so as to suppress an audio noise and an electromagnetic interference (EMI).

FIG. **2**D is a waveform diagram of the driving apparatus and the LED strings of FIG. **2**A. Referring to FIG. **2**A and FIG. **2**D, in the present embodiment, assuming the driving apparatus **200** only drives the LED strings **50_1** and **50_2**, and the duty cycle of the received dimming signal Sdim is 1/4. Now, the switches SW**1** and SW**2** are respectively conducted according to the received control signals Sco**1**, and the conducting time thereof is respectively T/2. Moreover, the current driving unit **250** regulates the current magnitude D of each of the driving currents I_1-I_n to a half (i.e. 1/2) of a current upper limit H according to the control voltage Vco**1**, wherein the current upper limit H corresponds to a high level V of the voltage signal. Accordingly, the driving apparatus **200** can implement a 1/4 dimming effect, and the current magnitude D is approximately maintained to a half of the current upper limit H, so as to suppress the audio noise and the EMI.

FIG. **2**E is a schematic diagram illustrating the current control unit and the dimming detector of FIG. **2**A. Referring to FIG. **2**E, in the present embodiment, the current control unit **270** includes a multiplexer **271**, a disperse delay unit **272** and a duty cycle to voltage converter **273**. When the driving apparatus **200** performs the dimming and the duty cycle of the dimming signal Sdim is greater than or equal to the predetermined value, under a control of the dimming mode signal Smod output from the dimming detector **260**, a first output terminal of the multiplexer **271** outputs the dimming signal Sdim received by an input terminal thereof to the duty cycle to voltage converter **273**, so as to regulate a magnitude of the control voltage Vco**1** according to the duty cycle of the dimming signal Sdim. The current driving unit **250** synchronously regulates the current magnitudes of the driving currents I_1-I_n according to a magnitude of the control voltage Vco**1**. Meanwhile, since the disperse delay unit **272** does not receive the dimming signal Sdim, the control signals of the disperse delay unit **272** control the switches SW**1**-SWn to be simultaneously conducted, so as to simultaneously output the driving currents I_1-I_n to the LED strings **50_1**-**50**_n.

When the driving apparatus **200** performs the dimming and the duty cycle of the dimming signal Sdim is smaller than the predetermined value, under a control of the dimming mode signal Smod output from the dimming detector **260**, a second output terminal of the multiplexer **271** outputs the dimming signal Sdim received by the input terminal thereof to the disperse delay unit **272**. After the disperse delay unit **272** receives the dimming signal Sdim, the controls signals Sco**1** generated by the disperse delay unit **272** control the switches SW**1**-SWn to be respectively conducted during the period, wherein the conducting time of each of the switches SW**1**-SWn is identical. Generally, the control signals Sco**1** can separately transmit pulses to conduct the switches SW**1**-SWn at different time sections. The conducting time of the switches SW**1**-SWn are separated and consecutive, i.e. the pulses used for conducting the switches are consecutively output from the corresponding output terminals of the control signals Sco**1**, and a consecutive output effect thereof is equivalent to a pulse shifting effect. Wherein, the pulse shifting effect can be implemented by shift registers, namely, the function that the control signals Sco**1** transmit the pulses at different time sections can be implemented by shifting and outputting the pulses through a plurality of the shift registers.

Meanwhile, the disperse delay unit **272** transmits the received dimming signal Sdim to the duty cycle to voltage converter **273**, and simultaneously outputs a gain signal GN to the duty cycle to voltage converter **273**. The duty cycle to voltage converter **273** regulates the magnitude of the control voltage Vco**1** according to the duty cycle of the dimming signal Sdim and the gain signal GN, so as to synchronously regulate the magnitudes of the driving currents I_1-I_n. Wherein, the gain signal GN can transmit a gain, and the gain transmitted by the gain signal GN can be equal to a current number of the driving currents I_1-I_n. For example, if the current number of the driving currents I_1-I_n is 8, the gain transmitted by the gain signal GN is 8. For example, when the duty cycle of the dimming signal Sdim is 1/16, the current magnitude of each of the driving currents should be 1/16 of the current upper limit, though according to the gain signal GN, the current magnitude of each of the driving currents I_1-I_n is adjusted to be 1/2 of the current upper limit, and since the outputting time of each of the driving currents I_1-I_n is 1/8 of the period, a 1/16 dimming effect can be achieved.

It should be noticed that when the disperse delay unit **272** does not receive the dimming signal Sdim, the disperse delay unit **272** can output the gain signal GN with a gain of 1, or does not output the gain signal GN. Moreover, when the duty cycle to voltage converter **273** does not receive the gain signal GN, it can generate the corresponding control voltage Vco**1** according to the duty cycle of the dimming signal Sdim.

FIG. **2**F is a schematic diagram illustrating the duty cycle to voltage converter of FIG. **2**E. Referring to FIG. **2**F, in the present embodiment, the duty cycle to voltage converter **273** includes a low pass filter circuit LPF**1** and an analog multiplier ML**1**, wherein the low pass filter circuit LPF**1** can be formed by a resistor R**1** and a capacitor C**1**, though the present invention is not limited thereto. The low pass filter circuit LPF**1** can convert the received dimming signal Sdim into a DC level, i.e. the low pass filter circuit LPF**1** can output different DC levels according to different duty cycles of the dimming signal Sdim. The analog multiplier ML**1** can amplify the DC level output from the low pass filter circuit LPF**1** to serve as the control voltage Vco**1** according to the gain signal GN. When the gain transmitted by the gain signal GN is 1, a level of the control voltage Vco**1** is the same to the DC level output by the low pass filter circuit LPF**1**. When the gain transmitted by the gain signal GN is 2, the level of the control voltage Vco**1** is twice of the DC level output by the low pass filter circuit LPF**1**, and the others are deduced by analogy.

FIG. **2**G is another schematic diagram illustrating the duty cycle to voltage converter of FIG. **2**E. Referring to FIG. **2**F and FIG. **2**G, a difference there between lies in a multiplexer mux**1**. The multiplexer mux**1** determines whether to transmit the DC level output from the low pass filter circuit LPF**1** to the analog multiplier ML**1** or directly output the DC level according to the dimming mode signal Smod. In other words, when the driving apparatus **200** performs the dimming, and the duty cycle of the dimming signal Sdim is greater than or equal to the predetermined value, the DC level output by the low pass filter circuit LPF**1** is directly output as the control voltage Vco**1**. When the driving apparatus **200** performs the dimming, and the duty cycle of the dimming signal Sdim is smaller than the predetermined value, the DC level output by the low pass filter circuit LPF**1** is transmitted to the analog multiplier ML**1**, so as to be amplified according to the gain signal GN and output as the control voltage Vco**1**.

FIG. **2**H is another schematic diagram illustrating the current control unit and the dimming detector of FIG. **2**A. Referring to FIG. **2**E and FIG. **2**H, differences there between lie in the disperse delay unit **274** and the omitted multiplexer **271**. When the driving apparatus **200** performs the dimming, and the duty cycle of the dimming signal Sdim is greater than or equal to the predetermined value, the disperse delay unit **274** generates the control signals Sco**1** according to the dimming mode signal Smod, so as to control the switches SW**1**-SWn to be simultaneously conducted, wherein the disperse delay unit **274** does not output the gain signal GN or outputs the gain signal GN with the gain of 1. In case that the disperse delay unit **274** does not output the gain signal GN, the duty cycle to voltage converter **273** can generate the control voltage Vco**1** according to the received dimming signal Sdim. In case that the disperse delay unit **274** outputs the gain signal GN with the gain of 1, the duty cycle to voltage converter **273** can generate the control voltage Vco**1** according to the received dimming signal Sdim and the gain signal GN.

When the driving apparatus **200** performs the dimming, and the duty cycle of the dimming signal Sdim is smaller than the predetermined value, the disperse delay unit **274** generates the control signals Sco**1** according to the dimming mode signal Smod, so as to control the switches SW**1**-SWn to be respectively conducted in one period, and the disperse delay unit **274** outputs the gain signal GN corresponding to the current number of the driving currents I_1-I_n. The duty cycle to voltage converter **273** can generate the control voltage Vco**1** according to the received dimming signal Sdim and the gain signal GN.

FIG. **2**I is still another schematic diagram illustrating the current control unit and the dimming detector of FIG. **2**A. Referring to FIG. **2**I, the current number of the driving currents I_1-I_n is, for example, 8, i.e. the predetermined value is 1/8. The dimming detector **260** includes a low pass filter circuit LPF**2**, an analog-to-digital converter (ADC) **261** and an OR gate **262**, wherein the ADC **261** is, for example, a 4 bits ADC. If the duty cycle of the dimming signal Sdim is 1/4, the ADC **261** outputs "0100", which is "0100 0000" in a digital type. The predetermined value is "0010 0000" in the digital type.

According to the above description, as long as one of the front three highest bits has a value of 1, it is considered to be greater than the predetermined value, so that an OR operation can be performed to the front three highest bits to generate the dimming mode signal Smod. After the OR gate **262** operates the front three highest bits of "0100 0000" output by the ADC **261**, the dimming mode signal Smod with a high logic level is generated, which represents that the duty cycle of the dimming signal Sdim is greater than the predetermined value. Thereafter, the multiplexer **271** outputs "0100 0000" transmitted from the ADC **261** to a duty cycle to voltage converter **276** according to the dimming mode signal Smod, so as to convert the digital type "0100 0000" into an analog type and output it as the control voltage Vco**1**, wherein the duty cycle to voltage converter **276** can include a digital-to-analog converter (DAC) for converting the digital type "0100 0000" into the analog type. Moreover, when the disperse delay unit **275** does not receive the output of the ADC **261**, it can correspondingly generate a plurality of the control signals Sco**1** to simultaneously conduct the switches SW**1**-SWn.

If the duty cycle of the dimming signal Sdim is 1/16, the ADC **261** outputs "0001 0000", and after the OR gate **262** operates the front three highest bits thereof, the dimming mode signal Smod with a low logic level is generated. Thereafter, the multiplexer **271** outputs "0001 0000" transmitted from the ADC **261** to the duty cycle to voltage converter **276** according to the dimming mode signal Smod. Now, the disperse delay unit **275** correspondingly generates a plurality of the control signals Sco**1** to control the switches SW**1**-SWn to be respectively conducted during one period. Moreover, the disperse delay unit **275** regulates the output "0001 0000" of the ADC **261** according to the predetermined value, i.e. "0001 0000" is multiplied by 8 (which is equivalent to left-shift three bits) to obtain "1000 0000". Taking "1000 0000" as the gain signal, the duty cycle to voltage converter **276** converts "1000 0000" into an analog type and outputs it as the control voltage Vco**1**. It should be noticed that in the present embodiment, the duty cycle to voltage converter **276** does not receive the dimming signal Sdim, so as to reduce a complexity of a circuit design.

According to the above description, a driving method for the driving apparatus **200** can be deduced. FIG. **3**A is a flowchart illustrating a driving method according to an embodiment of the present invention. Referring to FIG. **2**A and FIG. **3**A, the driving apparatus **200** receives the dimming signal Sdim, and whether the driving apparatus **200** performs the dimming can be detected according to the dimming signal Sdim (step S**301**). When the driving apparatus **200** performs the dimming, the outputting time of the driving currents are equally allotted in a period (step S**302**), and the driving apparatus **200** can output the driving currents I_1-I_n to respectively drive the LED strings **50_1-50**_n. When the driving apparatus **200** does not perform the dimming, the driving method is ended.

FIG. **3**B is a flowchart illustrating a driving method according to another embodiment of the present invention. Referring to FIG. **3**A and FIG. **3**B, a difference there between lies in steps **S311**, **S312** and **S313**. When the driving apparatus performs the dimming, it is determined whether the duty cycle of the dimming signal is smaller than the predetermined value (step S**311**). If the duty cycle of the dimming signal is not smaller than the predetermined value, the driving currents are simultaneously output during the period, and the current magnitudes of the driving currents are regulated according to the dimming signal (step S**312**). If the duty cycle of the dimming signal is smaller than the predetermined value, the outputting time of the driving currents are equally allotted in the period, and the current magnitudes of the driving currents are correspondingly regulated (step S**313**). Wherein, the aforementioned embodiments can be referred for the steps **S312** and **S313**, and therefore detailed descriptions thereof are not repeated.

In summary, according to the driving apparatus of the LED of the present invention and the driving method thereof, when the driving apparatus performs the dimming and the duty cycle of the dimming signal is smaller than the predetermined value, the outputting time of the driving currents are equally allotted in the period, and the current magnitude of each of the driving currents is correspondingly regulated. When the driving apparatus performs the dimming and the duty cycle of the dimming signal is equal to or greater than the predetermined value, the driving currents are simultaneously output in the period, and the current magnitude of each of the driving currents is regulated according to the dimming signal. By such means, the audio noise and the EMI caused by excessive variation of a sum of the driving currents are suppressed.

It will be apparent to those skilled in the art that various modifications and variations can be made to the structure of the present invention without departing from the scope or spirit of the invention. In view of the foregoing, it is intended that the present invention cover modifications and variations of this invention provided they fall within the scope of the following claims and their equivalents.

What is claimed is:

[1. A driving method of a light-emitting diode (LED), adapted to a driving apparatus, the driving method comprising:

detecting whether the driving apparatus performs dimming;

if the driving apparatus is detected to perform dimming, determining whether a predetermined requirement for dimming control is met or not;

when the predetermined requirement for dimming control is not met, regulating respective current magnitudes of a plurality of driving currents, and outputting each of the driving currents for a full time of a period; and

when the predetermined requirement for dimming control is met, outputting each of the driving currents for a partial time of a period.**]**

[2. The driving method of the LED as claimed in claim **1**, wherein

the driving method further comprises receiving a dimming signal, and

the step of determining whether the predetermined requirement for dimming control is met or not is performed according to the dimming signal.**]**

[3. The driving method of the LED as claimed in claim **2**, wherein the step of determining whether the predetermined requirement for dimming control is met or not according to the dimming signal comprises determining whether a duty cycle of the dimming signal is smaller than a predetermined value or not.**]**

[4. The driving method of the LED as claimed in claim **1**, wherein in a situation where the predetermined requirement for dimming control is not met, the respective current magnitudes of the plurality of driving currents are regulated according to the dimming signal.**]**

[5. The driving method of the LED as claimed in claim **4**, wherein in the situation where the predetermined requirement for dimming control is not met, the respective current magnitudes of the plurality of driving currents are determined according to the duty cycle of the dimming signal.**]**

[6. The driving method of the LED as claimed in claim **1**, further comprising:

in a situation where the predetermined requirement for dimming control is met, arranging a respective current magnitude and a respective outputting time of each of the driving currents in a period according to the dimming signal.**]**

[7. The driving method of the LED as claimed in claim **6**, wherein in the situation where the predetermined requirement for dimming control is met, the respective current magnitude and the respective outputting time of each of the driving currents in the period are determined according to the duty cycle of the dimming signal.**]**

[8. The driving method of the LED as claimed in claim **1**, further comprising: regardless of whether each of the driving currents is output for the full time or the partial time of the period, maintaining a sum of the driving currents calculated for a period approximately to a fixed value for a same duty cycle of the dimming signal.]

[9. A driving method of a light-emitting diode (LED), adapted to a driving apparatus, the driving method comprising:

receiving a dimming signal;

detecting whether the driving apparatus performs dimming;

if the driving apparatus is detected to perform dimming, regulating at least one of a respective current magnitude and a respective outputting time of each of a plurality of driving currents in a period according to a duty cycle of the dimming signal, such that a sum of the driving currents calculated for a period is substantially proportional to the duty cycle of the dimming signal.]

[10. The driving method of the LED as claimed in claim 9, wherein

in at least one of the regulations, only the respective current magnitude of each of the driving currents is regulated according to the duty cycle of the dimming signal, and

in at least another one of the regulations, both the respective current magnitude and the outputting time of each of the driving currents in the period are regulated according to the duty cycle of the dimming signal.]

[11. The driving method of the LED as claimed in claim 9, wherein

in at least one of the regulations, each of the driving currents is output for a full time of the period, and

in at least another one of the regulations, each of the driving currents is output for a partial time of the period.]

[12. The driving method of the LED as claimed in claim 11, wherein whether each of the driving currents is output for the partial time of the period or the full time of the period is determined according to whether the duty cycle of the dimming signal is smaller than a predetermined value or not.]

[13. The driving method of the LED as claimed in claim 11, wherein for the regulations for a same duty cycle of the dimming signal, regardless of whether each of the driving currents is output for the full time or the partial time of the period, a sum of the driving currents calculated for the period is substantially maintained to a fixed value.]

14. A driving circuit for driving a plurality of light-emitting diodes (LEDs), the driving circuit comprising:

a plurality of switches, used to be coupled to the LEDs;

a dimming detector, for receiving a dimming signal and outputting a dimming mode signal according to the dimming signal;

a current control unit, for outputting a plurality of control signals according to the dimming mode signal and the dimming signal, wherein the control signals respectively control conducting states of the switches,

wherein the driving circuit further comprises a current driving unit coupled between the switches and the current control unit, and the current control unit further outputs a control voltage according to the dimming mode signal and the dimming signal, wherein the control voltage controls the current driving unit to regulate a plurality of driving currents for driving the LEDs.

[15. The driving circuit as claimed in claim **14**, wherein the driving circuit further comprises a current driving unit coupled between the switches and the current control unit, and

the current control unit further outputs a control voltage according to the dimming mode signal and the dimming signal, wherein the control voltage controls the current driving unit to regulate a plurality of driving currents for driving the LEDs.]

16. The driving circuit as claimed in claim **14**, wherein the dimming detector detects whether dimming is performed according to the dimming signal and outputs the dimming mode signal according to the detection result.

17. The driving circuit as claimed in claim **16**, wherein the dimming detector detects whether dimming is performed by detecting a duty cycle of the dimming signal.

18. The driving circuit as claimed in claim **16**, wherein the dimming detector further detects whether a duty cycle of the dimming signal is smaller than a predetermined value or not so as to output the dimming mode signal to the current control unit for arranging the status of the switches.

19. [The driving circuit as claimed in claim **18**, wherein] *A driving circuit for driving a plurality of light-emitting diodes (LEDs), the driving circuit comprising:*

a plurality of switches, used to be coupled to the LEDs;

a dimming detector, for receiving a dimming signal and outputting a dimming mode signal according to the dimming signal;

a current control unit, for outputting a plurality of control signals according to the dimming mode signal and the dimming signal, wherein the control signals respectively control conducting states of the switches,

wherein the dimming detector detects whether dimming is performed according to the dimming signal and outputs the dimming mode signal according to the detection result, the dimming detector further detects whether a duty cycle of the dimming signal is smaller than a predetermined value or not so as to output the dimming mode signal to the current control unit for arranging the status of the switches, and the dimming detector detects whether the duty cycle of the dimming signal is smaller than the predetermined value or not so as to further output the dimming signal to the current control unit, such that the current control unit controls the current driving unit to regulate driving currents for driving the LEDs.

20. The driving circuit as claimed in claim **18**, wherein in a situation where the dimming detector detects that dimming is performed and the duty cycle of the dimming signal is smaller than the predetermined value, the current control unit outputs the control signals to control the switches to be conducted for a partial time of a period.

21. The driving circuit as claimed in claim **18**, wherein in a situation where the dimming detector detects that dimming is performed and the duty cycle of the dimming signal [is the duty cycle of the dimming signal] is not smaller than the predetermined value, the current control unit outputs the control signals to control each of the switches to be conducted for a full time of a period.

22. The driving circuit as claimed in claim **19**, wherein in a situation where the dimming detector detects that dimming is performed and the duty cycle of the dimming signal [is the duty cycle of the dimming signal] is smaller than the predetermined value, the current control unit outputs the control signals to control each of the switches to be conducted for a partial time of a period.

23. The driving circuit as claimed in claim **19**, regardless of whether a duty cycle of the dimming signal is smaller than the predetermined value or not, the driving currents are regulated such that a sum of the driving currents calculated for the period is substantially proportional to the duty cycle of the dimming signal.

[**24**. An electronic device, comprising

the driving circuit as claimed in claims **14**; and

a plurality of light-emitting diodes coupled to and driven by the driving circuit.]

25. A driving circuit for driving a plurality of light-emitting diodes (LEDs), the driving circuit comprising:

a plurality of switches, coupled to the LEDs;

a dimming detector, receiving a dimming signal and detecting a dimming control; and

a current control unit, coupled to the dimming detector, and responsive to a detection of the dimming control to output a plurality of control signals, wherein the control signals respectively control conducting states of the switches,

wherein the driving circuit further comprises a current driving unit coupled between the switches and the current control unit, the current control unit further outputs a control voltage in response to the detection of the dimming control, and the control voltage controls the current driving unit to regulate a plurality of driving currents for driving the LEDs.

26. The driving circuit as claimed in claim 25, wherein the current control unit controls the conducting state of each of the switches for a partial time of a period.

27. The driving circuit as claimed in claim 26, wherein conducting times of the switches are substantially equal to each other.

28. The driving circuit as claimed in claim 26, wherein conducting times of any two of the switches are not overlapped.

29. The driving circuit as claimed in claim 26, wherein the driving currents flowing through the switches are substantially equal to each other.

30. The driving circuit as claimed in claim 29, wherein a sum of current magnitudes of the driving currents flowing through the switches is substantially constant over the period.

31. The driving circuit as claimed in claim 25, wherein the dimming detector further detects a predetermined condition according to the dimming signal for determining ways of the dimming control.

32. The driving circuit as claimed in claim 31, wherein the dimming detector detects the predetermined condition by detecting a duty cycle of the dimming signal.

33. The driving circuit as claimed in claim 32, wherein the current control unit arranges the conducting states of the switches according to detection result of the predetermined condition.

34. The driving circuit as claimed in claim 33, wherein the current control unit controls the current driving unit to regulate the driving currents for driving the LEDs according to the detection result of the predetermined condition.

35. The driving circuit as claimed in claim 33, wherein when a first predetermined condition is detected, the current control unit outputs the control signals to control the switches to be conducted for a partial time of a period.

36. The driving circuit as claimed in claim 35, wherein when a second predetermined condition is detected, the current control unit outputs the control signals to control each of the switches to be conducted for a full time of a period.

37. The driving circuit as claimed in claim 36, regardless of the first predetermined condition or the second predetermined condition is detected, the driving currents are regulated such that a sum of the driving currents calculated for the period is substantially proportional to the duty cycle of the dimming signal.
