(57) **ABSTRACT**

A leadless pacing device (LPD) includes a motion sensor configured to generate a motion signal as a function of heart movement. The LPD is configured to analyze the motion signal within an atrial contraction detection window that begins an atrial contraction detection delay period after activation of the ventricle, and detect a contraction of an atrium of the heart based on the analysis of the motion signal within the atrial contraction detection window. If the LPD does not detect a ventricular depolarization subsequent to the atrial contraction, e.g., with an atrio-ventricular (AV) interval beginning when the atrial contraction was detected, the LPD delivers a ventricular pacing pulse.

**ATRIAL CONTRACTION DETECTION BY A
VENTRICULAR LEADLESS PACING
DEVICE FOR ATRIO-SYNCHRONOUS
VENTRICULAR PACING**

Matter enclosed in heavy brackets [] appears in the original patent but forms no part of this reissue specification; matter printed in italics indicates the additions made by reissue; a claim printed with strikethrough indicates that the claim was canceled, disclaimed, or held invalid by a prior post-patent action or proceeding.

This application claims the benefit of U.S. Provisional Application No. 62/028,957, filed Jul. 25, 2014, the entire contents of which are incorporated herein by reference.

TECHNICAL FIELD

The disclosure relates to cardiac pacing, and more particularly, to cardiac pacing using a leadless pacing device.

BACKGROUND

An implantable pacemaker may deliver pacing pulses to a patient's heart and monitor conditions of the patient's heart. In some examples, the implantable pacemaker comprises a pulse generator and one or more electrical leads. The pulse generator may, for example, be implanted in a small pocket in the patient's chest. The electrical leads may be coupled to the pulse generator, which may contain circuitry that generates pacing pulses and/or senses cardiac electrical activity. The electrical leads may extend from the pulse generator to a target site (e.g., an atrium and/or a ventricle) such that electrodes at the distal ends of the electrical leads are positioned at a target site. The pulse generator may provide electrical stimulation to the target site and/or monitor cardiac electrical activity at the target site via the electrodes.

A leadless pacing device has also been proposed for sensing electrical activity and/or delivering therapeutic electrical signals to the heart. The leadless pacing device may include one or more electrodes on its outer housing to deliver therapeutic electrical signals and/or sense intrinsic depolarizations of the heart. The leadless pacing device may be positioned within or outside of the heart and, in some examples, may be anchored to a wall of the heart via a fixation mechanism.

SUMMARY

The disclosure describes a leadless pacing device (hereinafter, "LPD") that is configured for implantation in a ventricle of a heart of a patient, and is configured to deliver atrio-synchronous ventricular pacing based on detection of atrial contraction. More particularly, the LPD includes a motion sensor configured to generate a motion signal as a function of heart movement. The motion sensor may include one or more accelerometers, which may have a single axis, or multiple axes. The LPD is configured to analyze the motion signal within an atrial contraction detection window. The atrial contraction detection window begins upon completion of an atrial contraction detection delay period, which begins upon detection of activation of the ventricle. The LPD is configured to detect a contraction of an atrium of the heart based on the analysis of the motion signal within

the atrial contraction detection window. If the LPD does not detect a ventricular depolarization subsequent to the atrial contraction, e.g., within an atrioventricular (AV) interval beginning when the atrial contraction was detected, the LPD delivers a ventricular pacing pulse. In some examples, the LPD is configured to deliver atrio-synchronous ventricular pacing using an electrical AV interval based on detection of atrial depolarizations via a plurality of electrodes of the LPD and, if the LPD is unable to detect atrial depolarizations, switch to delivering atrio-synchronous ventricular pacing using a mechanical AV interval, which may be shorter than the electrical AV interval, based on detection of atrial contractions.

In one example, a leadless pacing device is configured to provide atrio-synchronous ventricular pacing. The leadless pacing device comprises a plurality of electrodes, a motion sensor configured to generate a motion signal as a function of movement of a heart of a patient, a stimulation module coupled to the plurality of electrodes, wherein the stimulation module is configured to generate pacing pulses and deliver the pacing pulses to a ventricle of the heart via the plurality of electrodes, and an electrical sensing module coupled to the plurality of electrodes, wherein the electrical sensing module is configured to detect depolarizations of the ventricle within a cardiac electrogram sensed via the plurality of electrodes. The leadless pacing device further comprises a mechanical sensing module coupled to the motion sensor. The mechanical sensing module is configured to receive the motion signal from the motion sensor, identify an activation of the ventricle and, upon identification of the activation of the ventricle, initiate an atrial contraction detection delay period. The mechanical sensing module is further configured to analyze the motion signal within an atrial contraction detection window that begins upon completion of the atrial contraction detection delay period, and detect a contraction of an atrium of the heart based on the analysis of the motion signal within the atrial contraction detection window. The leadless pacing device further comprises a processing module configured to control the stimulation module to generate a pacing pulse and deliver the pacing pulse to the ventricle via the plurality of electrodes in response to the detection of the contraction of the atrium by the mechanical sensing module. The leadless pacing device further comprises a housing configured to be implanted within the ventricle, wherein the housing encloses the motion sensor, the stimulation module, the electrical sensing module, the mechanical sensing module, and the processing module.

In another example, a method for providing atrio-synchronous ventricular pacing by a leadless pacing device implanted within a ventricle of a heart of a patient comprises identifying an activation of the ventricle, upon identification of the activation of the ventricle, initiating an atrial contraction detection delay period, and analyzing a motion signal within an atrial contraction detection window that begins upon completion of the atrial contraction detection delay period. The motion signal is generated by a motion sensor of the leadless pacing device as a function of movement of the heart. The method further comprises detecting a contraction of an atrium of the heart based on the analysis of the motion signal within the atrial contraction detection window, and delivering a pacing pulse to the ventricle in response to the detection of the contraction of the atrium.

In another example, a leadless pacing device is configured to provide atrio-synchronous ventricular pacing. The leadless pacing device comprises means for generating a motion signal as a function of movement of a heart of a patient,

3

means for identifying an activation of a ventricle of the heart, means for initiating an atrial contraction detection delay period upon identification of the activation of the ventricle, and means for analyzing the motion signal within an atrial contraction detection window that begins upon completion of the atrial contraction detection delay period. The leadless pacing device further comprises means for detecting a contraction of an atrium of the heart based on the analysis of the motion signal within the atrial contraction detection window, and means for delivering a pacing pulse to the ventricle in response to the detection of the contraction of the atrium.

In another example, a computer-readable storage medium comprises instructions stored thereon that, when executed by one or more programmable processors of a leadless pacing device configured to provide atrio-synchronous ventricular pacing, cause the one or more processors to identify an activation of the ventricle, upon identification of the activation of the ventricle, initiate an atrial contraction detection delay period, and analyze a motion signal within an atrial contraction detection window that begins upon completion of the atrial contraction detection delay period. The motion signal is generated by a motion sensor of the leadless pacing device as a function of movement of the heart. The instructions further cause the one or more processors to detect a contraction of an atrium of the heart based on the analysis of the motion signal within the atrial contraction detection window, and control delivery of a pacing pulse to the ventricle in response to the detection of the contraction of the atrium.

The details of one or more examples are set forth in the accompanying drawings and the description below. Other features, objects, and advantages will be apparent from the description and drawings, and from the claims.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a conceptual diagram illustrating an example leadless pacing system that comprises an example leadless pacing device configured to deliver atrio-synchronous ventricular pacing based on atrial contraction detection implanted within a patient.

FIG. 2 is a conceptual diagram further illustrating the example leadless pacing device of FIG. 1.

FIG. 3 is a conceptual diagram illustrating another example leadless pacing system that comprises another example leadless pacing device configured to deliver atrio-synchronous ventricular pacing based on atrial contraction detection implanted within a patient.

FIG. 4 is a functional block diagram illustrating an example configuration of a leadless pacing device configured to deliver atrio-synchronous ventricular pacing based on atrial contraction detection.

FIG. 5 is a graph illustrating a cardiac electrogram and a corresponding motion signal.

FIG. 6 is a timing diagram illustrating an example technique for delivering atrio-synchronous ventricular pacing based on atrial contraction detection.

FIG. 7 is a flow diagram of an example technique for delivering atrio-synchronous ventricular pacing based on atrial contraction detection that may be performed by a leadless pacing device implanted within a ventricle.

FIG. 8 is a flow diagram illustrating an example technique for detecting an atrial contraction based on analysis of a motion signal that may be performed by a leadless pacing device implanted within a ventricle.

4

FIG. 9 is a flow diagram illustrating an example technique for verifying efficacy of atrio-synchronous ventricular pacing based on atrial contraction detection that may be performed by a leadless pacing device implanted within a ventricle.

FIG. 10 is a flow diagram illustrating an example technique for switching between an atrio-synchronous ventricular pacing mode and an asynchronous pacing mode that may be performed by a leadless pacing device implanted within a ventricle.

FIG. 11 is a flow diagram illustrating an example technique for switching between atrio-synchronous ventricular pacing in response to atrial depolarizations and atrio-synchronous ventricular pacing in response to atrial contractions that may be performed by a leadless pacing device implanted within a ventricle.

DETAILED DESCRIPTION

Typically, dual-chamber implantable pacemakers are implanted within a pocket within the patient's chest, and coupled to a right-atrial lead and a right-ventricular lead. The right-atrial lead extends from the implantable pacemaker in the pocket to the right atrium of the patient's heart, and positions one or more electrodes within the right atrium. The right-ventricular lead extends from the implantable pacemaker in the pocket to the right ventricle of the patient's heart, and positions one or more electrodes within the right ventricle.

Such dual-chamber implantable pacemakers sense respective cardiac electrical activity, e.g., respective cardiac electrograms, via the one or more electrodes implanted within the right atrium and the one or more electrodes implanted within the right ventricle. In particular, such dual-chamber implantable pacemakers detect intrinsic atrial depolarizations via the one or more electrodes implanted within the right atrium, and intrinsic ventricular depolarizations via the one or more electrodes implanted within the right ventricle. The implantable pacemakers may also deliver pacing pulses to the right atrium and the right ventricle via the one or more electrodes in the right atrium and the right ventricle, respectively. Due to the ability to sense both atrial and ventricular electrical activity, such dual-chamber implantable pacemakers may be able to provide atrio-synchronous ventricular pacing. For patients with intermittent AV node conduction, it may be preferable to inhibit ventricular pacing and allow an intrinsic ventricular depolarization to occur for a time, referred to as the AV interval, after an intrinsic atrial depolarization or atrial pace. Such atrio-synchronous pacing in dual-chamber implantable pacemakers may be according to the VDD or DDD programming modes, which have been used to treat patients with various degrees of AV block.

Implantable cardiac leads and the pocket in which pacemakers are implanted may be associated with complications. To avoid such complications leadless pacing devices sized to be implanted entirely within one chamber, e.g., the right ventricle, of the heart have been proposed. Some proposed leadless pacemakers include a plurality of electrodes that are affixed to, or are a portion of, the housing of the leadless pacing device.

Some proposed leadless pacing devices are capable of sensing intrinsic depolarizations of, and delivering pacing pulses to, the chamber of the heart in which they are implanted via the plurality of electrodes. However, because they are not coupled to electrodes in any other chamber, some proposed leadless pacing devices are incapable of sensing intrinsic depolarizations of, and delivering pacing

5

pulses to, another chamber of the heart. Consequently, when implanted in the right ventricle, for example, such proposed leadless pacing devices may be unable to sense intrinsic atrial depolarizations of the atria, and may be limited to delivery of ventricular pacing according to an asynchronous ventricular pacing, e.g., according to a VVI or VVIR mode.

FIG. 1 is a conceptual diagram illustrating an example leadless pacing system 10A that comprises an example leadless pacing device (LPD) 12A that is configured to deliver atrio-synchronous ventricular pacing based on atrial contraction detection. In the example of FIG. 1, LPD 12A is implanted within right ventricle 18 of heart 16 of patient 14. More particularly, LPD 12A is fixed or attached to the inner wall of the right ventricle 18 proximate to the apex of the right ventricle in the example of FIG. 1. In other examples, LPD 12A may be fixed to the inner wall of right ventricle 18 at another location, e.g., on the intraventricular septum or free-wall of the right ventricle, or may be fixed to the outside of heart 16, i.e., epicardially, proximate to right ventricle 18. In other examples, LPD may be fixed within, on, or near the left-ventricle of heart 16.

LPD 12A includes a plurality of electrodes that are affixed to, or are a portion of, the housing of LPD 12A. LPD 12A senses electrical signals associated with depolarization and repolarization of heart 16, i.e., a cardiac electrogram signal, via the electrodes. LPD 12A also delivers cardiac pacing pulses to right ventricle 18 via the electrodes.

LPD 12A detects depolarizations of right ventricle 18 within the cardiac electrogram. In some examples, LPD 12A is not configured to detect intrinsic depolarizations of an atrium, e.g., right atrium 20, or the atria of heart 16 generally, within the cardiac electrogram signal. In other examples, LPD 12A is configured to detect atrial depolarizations within the cardiac electrogram signal. In some examples, LDP 12A is configured to detect atrial depolarizations with the cardiac electrogram signal, but may, at times, be unable to reliably detect atrial depolarizations, e.g., due to the quality of the cardiac electrogram signal, or the relatively small magnitude of the atrial depolarizations within a cardiac electrogram signal sensed via electrodes disposed within right ventricle 18. LPD 12A is configured to detect mechanical contractions of an atrium, e.g., right atrium 20, or the atria of heart 16 generally, e.g., as an alternative to sensing electrical depolarizations of right atrium 20. In this manner, LPD 12A may be configured to deliver atrio-synchronous ventricular pacing to right ventricle 18 even when not configured, or unable, to detect atrial depolarizations.

As described in greater detail below, LPD 12A includes a motion sensor configured to generate a motion signal as a function of movement of a heart of a patient. LPD 12A is configured to identify an activation event of right ventricle 18, and analyze the motion signal within an atrial contraction detection window that begins upon completion of an atrial contraction detection delay period that is initiated upon detection of the activation of the ventricle. The activation of the ventricle may be an intrinsic depolarization of the ventricle or delivery of a pacing pulse to the ventricle. In some examples, LPD 12A may be configured to detect contraction of right ventricle 18 based on the motion signal, and identify activation of the ventricle based on the detected ventricular contraction.

LPD 12A is configured to detect an atrial contraction based on the analysis of the motion signal within the atrial contraction detection window. If a subsequent intrinsic depolarization of right ventricle 18 is not detected, e.g., within an AV interval beginning when the atrial contraction

6

was detected, LPD 12A is further configured to deliver the pacing pulse to right ventricle 18. In this manner, LPD 12A is configured to deliver atrio-synchronous pacing to right ventricle 18 based on detection of atrial contractions.

In some examples, LPD 12A is configured to assess the efficacy of the delivery of atrio-synchronous pacing to right ventricle 18. For example, LPD 12A may detect a resulting contraction of right ventricle 18 based on the motion signal after delivery of a pacing pulse to the right ventricle, and determine whether the delivery of the pacing pulse to the right ventricle was effective based on the detection of the contraction of the right ventricle. In some examples, LPD 12A may determine one or more metrics of the ventricular contraction, such as a timing or amplitude of the ventricular contraction, and adjust the delivery of the ventricular pacing based on the one or more metrics. LPD 12A may adjust the AV interval, which begins upon detection of atrial contraction, based on the one or more metrics, as one example.

In addition to the motion of the heart, a motion signal generated by the motion sensor of LPD 12A may include more general motion of patient 14 due to patient activity or experienced by patient, e.g., driving in a car. Such motion of patient 14 may interfere with the ability of LPD 12A to detect atrial contractions. In some examples, LPD 12A is configured to determine an amount of motion of patient 14 based on the motion signal, and change from delivery of ventricular pacing according to an atrio-synchronous pacing mode to delivery of ventricular pacing according to an asynchronous pacing mode in response to determining that the amount of patient motion exceeds a threshold. In some examples, LPD 12A is additionally or alternatively configured to change from delivery of ventricular pacing according to an atrio-synchronous pacing mode to delivery of ventricular pacing according to an asynchronous pacing mode in response to determining that the heart rate is relatively high and/or irregular, e.g., based on intervals between successive intrinsic ventricular depolarizations and a stored threshold value, such as approximately 100 beats-per-minute (bpm). In some examples, LPD 12A is additionally or alternatively configured to change from delivery of ventricular pacing according to an atrio-synchronous pacing mode to delivery of ventricular pacing according to an asynchronous pacing mode in response to determining that an atrial contraction was not detected during a predetermined number of cardiac cycles. According to an asynchronous ventricular pacing mode, e.g., VVI or VVIR, LPD 12A delivers a ventricular pacing pulse if an intrinsic ventricular depolarization is not detected within a VV interval that begins when a previous intrinsic ventricular depolarization was detected, or a previous ventricular pacing pulse was delivered.

As illustrated in FIG. 1, leadless pacing system 10A also includes a medical device programmer 22, which is configured to program LPD 12A and retrieve data from LPD 12A. Programmer 22 may be a handheld computing device, desktop computing device, a networked computing device, or any other type of computing device, as examples. Programmer 22 may include a computer-readable storage medium having instructions that cause a processor of programmer 22 to provide the functions attributed to programmer 22 in the present disclosure. LPD 12A may wirelessly communicate with programmer 22. For example, LPD 12A may transfer data to programmer 22 and may receive data from programmer 22. Programmer 22 may also wirelessly program and/or wirelessly charge LPD 12A.

Data retrieved from LPD 12A using programmer 22 may include cardiac electrograms and motion signals stored by LPD 12A that indicate the electrical and mechanical activity

of heart 16, and marker channel data that indicates the occurrence and timing of sensing, diagnosis, and therapy events associated with LPD 12A, e.g., detection of atrial and ventricular depolarizations, atrial and ventricular contractions, and delivery of pacing pulses. Data transferred to LPD 12A using programmer 22 may include, for example, operational programs for LPD 12A that causes LPD 12A to operate as described herein. As examples, data transferred to LPD 12A using programmer 22 may include lengths of any AV intervals, atrial contraction detection delay periods, and atrial contraction detection windows described herein, any threshold values, such as for detecting atrial and/or ventricular contractions, or programming used by LPD 12A to determine such values based on determined parameters of heart 16, patient 14, or LPD 12A.

FIG. 2 is a conceptual diagram further illustrating LPD 12A. As illustrated in FIG. 2, LPD 12A includes an outer housing 30, fixation tines 32A-32D (collectively "fixation tines 32"), and electrodes 34 and 36. Outer housing 30 is configured to allow, e.g., has a size and form factor that allows, LPD 12A to be entirely implanted within a chamber of heart 16, such as right ventricle 18. As illustrated in FIG. 2, housing 30 may have a cylindrical (e.g., pill-shaped) form factor in some examples. Housing 30 may be hermetically sealed to prevent ingress of fluids into the interior of housing 30.

Fixation tines 32 extend from outer housing 30, and are configured to engage with cardiac tissue to substantially fix a position of housing 30 within a chamber of heart 16, e.g., at or near an apex of right ventricle 18. Fixation tines 32 are configured to anchor housing 30 to the cardiac tissue such that LPD 12A moves along with the cardiac tissue during cardiac contractions. Fixation tines 32 may be fabricated from any suitable material, such as a shape memory material (e.g., Nitinol). The number and configuration of fixation tines 32 illustrated in FIG. 2 is merely one example, and other numbers and configurations of fixation tines for anchoring an LPD housing to cardiac tissue are contemplated. Additionally, although LPD 12A includes a plurality of fixation tines 32 that are configured to anchor LPD 12A to cardiac tissue in a chamber of a heart, in other examples, LPD 12A may be fixed to cardiac tissue using other types of fixation mechanisms, such as, but not limited to, barbs, coils, and the like.

LPD 12A is configured to sense electrical activity of heart 16, i.e., a cardiac electrogram, and deliver pacing pulses to right ventricle 18, via electrodes 34 and 36. Electrodes 34 and 36 may be mechanically connected to housing 30, or may be defined by a portion of housing 30 that is electrically conductive. In either case, electrodes are electrically isolated from each other. Electrode 34 may be referred to as a tip electrode, and fixation tines 32 may be configured to anchor LPD 12A to cardiac tissue such that electrode 34 maintains contact with the cardiac tissue. Electrode 36 may be defined by a conductive portion of housing 30 and, in some examples, may define at least part of a power source case that houses a power source (e.g., a battery) of LPD 12A. In some examples, a portion of housing 30 may be covered by, or formed from, an insulative material to isolate electrodes 34 and 36 from each other and/or to provide a desired size and shape for one or both of electrodes 34 and 36.

Outer housing 30 houses electronic components of LPD 12A, e.g., an electrical sensing module for sensing cardiac electrical activity via electrodes 34 and 36, a motion sensor, a mechanical sensing module for detecting cardiac contractions, and an electrical stimulation module for delivering pacing pulses via electrodes 34 and 36. Electronic compo-

nents may include any discrete and/or integrated electronic circuit components that implement analog and/or digital circuits capable of producing the functions attributed to an LPD described herein. Additionally, housing 30 may house a memory that includes instructions that, when executed by one or more processors housed within housing 30, cause LPD 12A to perform various functions attributed to LPD 12A herein. In some examples, housing 30 may house a communication module that enables LPD 12A to communicate with other electronic devices, such as medical device programmer 22. In some examples, housing 30 may house an antenna for wireless communication. Housing 30 may also house a power source, such as a battery.

FIG. 3 is a conceptual diagram illustrating another example leadless pacing system 10B that comprises another example LPD 12B configured to deliver atrio-synchronous ventricular pacing based on atrial contraction detection. Leadless pacing system 10B and LPD 12B may be substantially the same as leadless pacing system 10A and LPD 12A described above with respect to FIGS. 1 and 2. Unlike LPD 12A, however, LPD 12B includes a sensing extension 40 that includes an electrode 42. In some examples, sensing extension 40 may include one or more additional electrodes having the same polarity as electrode 42. Although not illustrated in FIG. 3, LPD 12B may include an electrode 34, but may not include electrode 36, as described above with respect to LPD 12A and FIG. 2.

Electrode 42 is electrically connected to electronics within a housing of LPD 12B (e.g., an electrical sensing module and a stimulation module) via an electrical conductor of sensing extension 40. In some examples, the electrical conductor of sensing extension 40 is connected to the electronics via an electrically conductive portion of the housing of LPD 12B, which may correspond to electrode 36 of LPD 12A (FIG. 2), but may be substantially completely insulated (e.g., completely electrically insulated or nearly completely electrically insulated). Substantially completely electrically insulating the conductive portion of the housing may allow an electrical sensing module of LPD 12B to sense electrical cardiac activity with electrode 42 of sensing extension 40, rather than the conductive portion of the housing.

Additionally, as shown in FIG. 3, sensing extension 40 extends away from LPD 12, which enables electrode 42 to be positioned relatively close to right atrium 20. As a result, a cardiac electrogram sensed by LPD 12B via electrodes 34 (FIGS. 2) and 42 may include a higher amplitude far-field atrial depolarization signal than a cardiac electrogram sensed by LPD 12A via electrodes 34 and 36 (FIG. 2). In this way, sensing extension 40 may facilitate detection of atrial depolarizations when LPD 12B is implanted in right ventricle 18. In some examples, sensing extension 40 is sized to be entirely implanted within right ventricle 18. In other examples, sensing extension 40 is sized to extend into right atrium 20.

LPD 12B is configured to detect atrial depolarizations within a cardiac electrogram signal. Accordingly, LPD 12B may be configured to deliver atrio-synchronous ventricular pacing based on detection of atrial depolarizations. For example, LPD 12B may be configured to deliver a pacing pulse to right ventricle 18 if an intrinsic depolarization of right ventricle 18 is not detected within an AV interval after detection of a depolarization of right atrium 20.

However, despite sensing extension 40, LPD 12B may, at times, be unable to detect depolarizations of right atrium 20, e.g., due to reduced cardiac electrogram signal quality. Reduced cardiac electrogram signal quality may include

reduced amplitude of the atrial component of the cardiac electrogram signal and/or increased noise. Reduced cardiac electrogram signal quality may be caused by, for example, movement of sensing extension **40** relative to right atrium **20**, which may be caused by posture or activity of patient **14**, or other conditions of patient **14**, heart **16**, and/or LPD **12B**. Consequently, LPD **12B** is also configured to detect atrial contractions, and deliver atrio-synchronous ventricular pacing based on the atrial contractions, as described with respect to LPD **12A**.

In some examples, LPD **12B** is configured to determine that an atrial depolarization was not detected during a cardiac cycle. For example, LPD **12B** may be configured to determine that an atrial depolarization was not detected between consecutive ventricular depolarizations. In some examples, in response to determining that a depolarization of the atrium was not detected during a predetermined number of cardiac cycles, LPD **12B** is configured to switch from delivering atrio-synchronous ventricular pacing based on detection of atrial depolarization and using an electrical AV interval, to delivering atrio-synchronous ventricular pacing based on detection of atrial contractions and using a mechanical AV interval. Because mechanical contraction of the atrium occurs after electrical depolarization of the atrium, the mechanical AV interval may be shorter than the electrical AV interval.

FIG. **4** is a functional block diagram illustrating an example configuration of an LPD **12A** to deliver atrio-synchronous ventricular pacing based on atrial contraction detection. LPD **12B** of FIG. **3** may have a similar configuration. However, electrode **36** of LPD **12A** may be replaced by electrode **42** of LPD **12B**, which may be positioned a greater distance away from electrode **34** and LPD **12B**, as described above with respect to FIG. **3**.

LPD **12A** includes a processing module **50**, memory **52**, stimulation module **54**, electrical sensing module **56**, motion sensor **58**, mechanical sensing module **60**, communication module **62**, and power source **64**. Power source **64** may include a battery, e.g., a rechargeable or non-rechargeable battery.

Modules included in LPD **12A** represent functionality that may be included in LPD **12A** of the present disclosure. Modules of the present disclosure may include any discrete and/or integrated electronic circuit components that implement analog and/or digital circuits capable of producing the functions attributed to the modules herein. For example, the modules may include analog circuits, e.g., amplification circuits, filtering circuits, and/or other signal conditioning circuits. The modules may also include digital circuits, e.g., combinational or sequential logic circuits, memory devices, and the like. The functions attributed to the modules herein may be embodied as one or more processors, hardware, firmware, software, or any combination thereof. Depiction of different features as modules is intended to highlight different functional aspects, and does not necessarily imply that such modules must be realized by separate hardware or software components. Rather, functionality associated with one or more modules may be performed by separate hardware or software components, or integrated within common or separate hardware or software components.

Processing module **50** may include any one or more of a microprocessor, a controller, a digital signal processor (DSP), an application specific integrated circuit (ASIC), a field-programmable gate array (FPGA), or equivalent discrete or integrated logic circuitry. In some examples, processing module **50** includes multiple components, such as any combination of one or more microprocessors, one or

more controllers, one or more DSPs, one or more ASICs, or one or more FPGAs, as well as other discrete or integrated logic circuitry. Additionally, although illustrated as separate functional components in FIG. **4**, some or all of the functionality attributed to stimulation module **54**, electrical sensing module **56**, mechanical sensing module **60**, and communication module **62** may be implemented in the one or more combination of one or more microprocessors, one or more controllers, one or more DSPs, one or more ASICs, one or more FPGAs, and/or other discrete or integrated logic circuitry that implements processing module **50**.

Processing module **50** may communicate with memory **52**. Memory **52** may include computer-readable instructions that, when executed by processing module **50**, cause processing module **50** and any other modules of LPD **12A** to perform the various functions attributed to them herein. Memory **52** may include any volatile, non-volatile, magnetic, or electrical media, such as a random access memory (RAM), read-only memory (ROM), non-volatile RAM (NVRAM), electrically-erasable programmable ROM (EEPROM), Flash memory, or any other memory device.

Stimulation module **54** and electrical sensing module **56** are electrically coupled to electrodes **34**, **36**. Processing module **50** is configured to control stimulation module **54** to generate and deliver pacing pulses to heart **16** (e.g., right ventricle **18** in the example shown in FIG. **1**) via electrodes **34**, **36**. In addition, processing module **50** is configured to control electrical sensing module **56** to monitor a signal from electrodes **34**, **36** in order to monitor electrical activity of heart **16**. Electrical sensing module **56** may include circuits that acquire an electrical signal from electrodes **34**, **36**, as well as circuits to filter, amplify, and otherwise process the electrical signal. The electrical signal includes intrinsic cardiac electrical activity, such as depolarizations and repolarizations of the ventricles and, in some cases, depolarizations of the atria, and may be referred to as a cardiac electrogram signal. Electrical sensing module **56** detects ventricular depolarizations within the cardiac electrogram signal and, in some examples, detects atrial depolarizations within the cardiac electrogram signal.

LPD **12A** also includes motion sensor **58**. In some examples, motion sensor **58** comprises one or more accelerometers. In some examples, motion sensor **58** comprises a plurality of accelerometers, e.g., three accelerometers, each of which is oriented to detect motion in the direction of a respective axis or vector. The axes or vectors may be orthogonal. In other examples, motion sensor **58** may comprise one or more different sensors that generate a signal as a function of motion, instead of or in addition to the one or more accelerometers, such as gyros, mercury switches, or bonded piezoelectric crystals.

Mechanical sensing module **60** includes circuitry to receive the motion signal from motion sensor **58**, as well as circuits to filter, amplify, and otherwise process the motion signal. Because LPD **12A** is affixed to heart **16**, motion sensor **60** generates a motion signal that varies as a function of motion of the heart, including motion associated with the contraction of the atria, and motion associated with the subsequent contraction of the ventricles. Because LPD **12A** is implanted within patient **14**, the motion signal generated by motion sensor **58** also varies as a function of any motion of (or experienced by) the patient, e.g., due to patient activity.

As described in greater detail below, mechanical sensing module **60** analyzes the motion signal generated by motion sensor **58** to detect contraction of an atrium. Mechanical sensing module **60** may also analyze the motion signal to

detect ventricular contraction. To detect atrial or ventricular contractions, mechanical sensing module 60 may filter the motion signal to exclude components other than cardiac motion, e.g., components of the motion signal associated with motion engaged in or experienced by patient 14. For example, to detect contraction of an atrium, mechanical sensing module 60 may high-pass filter the motion signal, e.g., to exclude frequencies lower than about 40 Hz. As another example, to detect contraction of a ventricle, mechanical sensing module 60 may high-pass filter the motion signal, e.g., to exclude frequencies lower than about 60 Hz.

Mechanical sensing module 60 may also analyze the motion signal to detect other parameters of patient 14, such as patient activity level. To detect patient activity level, mechanical sensing module 60 may filter the motion signal to exclude components other than those resulting from patient activity, such as components associated with cardiac contraction. For example, mechanical sensing module 60 may low-pass filter the motion signal generated by motion sensor 58, e.g., to exclude frequencies above about 40 Hz. Processing module 50 may control stimulation module 54 to deliver rate responsive ventricular pacing based on the activity level determined by motion sensing module 60. For example, processing module 50 may adjust an AV interval based on the activity level.

In examples in which motion sensor 58 includes a plurality of accelerometers or other sensors, a motion signal generated by motion sensor 58 may include one or more of the signals generated by the sensors, respectively, or a combination of one or more of the respective signals, which may be referred to as component signals of the motion signal. Mechanical sensing module 60 may derive the motion signal based on one or more of the component signals according to a sensing vector, where different sensing vectors specify a different one or more of the component signals. In some examples, mechanical sensing module 60 is configured to derive the motion signal according to a variety of different sensing vectors. In some examples, mechanical sensing module 60 may be configured to sense different parameters or events, e.g., atrial contractions, ventricular contractions, and patient activity, using different sensing vectors. In some examples, mechanical sensing module 60 is configured to detect an event or parameter, e.g., atrial contraction, according to a plurality of sensing vectors, and identify one or more sensing vectors that provide adequate detection of the event.

Communication module 62 may include any suitable hardware (e.g., an antenna), firmware, software, or any combination thereof for communicating with another device, such as programmer 22 (FIGS. 1 and 3) or a patient monitor. Under the control of processing module 50, communication module 62 may receive downlink telemetry from and send uplink telemetry to other devices, such as programmer 22 or a patient monitor, with the aid of an antenna included in communication module 62.

Memory 52 may include data recorded by LPD 12A, e.g., cardiac electrograms, motion signals, heart rates, information regarding detection of atrial contractions, ventricular pacing efficacy, etc. Under the direction of processing module 50, communication module 62 may transfer data recorded by LPD 12A to another device, such as programmer 22. Memory 52 may also store programming data received by processing module 50 from another device, such as programmer 22, via communication module 62. The programming data stored in memory 52 may include, as examples, lengths of any AV intervals, atrial contraction

detection delay periods, and atrial contraction detection windows described herein. The programming data stored in memory 52 may additionally or alternatively include any threshold values described herein, such as for detecting atrial and/or ventricular contractions, determining whether pacing is efficacious, or determining whether atrio-synchronous ventricular pacing should be suspended in favor of asynchronous pacing. The programming data stored in memory 52 may additionally or alternatively include data used by processing module 50 to determine any values described herein, e.g., based determined parameters of heart 16, patient 14, or LPD 12A.

FIG. 5 is a graph illustrating a cardiac electrogram signal 70 and a corresponding motion signal 72 generated by one or more accelerometers. Cardiac electrogram signal 70 includes ventricular depolarizations (R-waves) 74A and 74B, and corresponding ventricular repolarizations (T-waves) 76A and 76B. A cardiac cycle 78 may be defined as the period from one ventricular depolarization 74A to the next ventricular depolarization 74B, or the period between any repeating fiducial features of cardiac electrogram signal 70 or motion signal 72.

As illustrated by FIG. 5, cardiac cycle 78 includes an ejection phase, which may also be referred to as systole. During the ejection phase a ventricular contraction 80A occurs as a result of ventricular depolarization 74A. The S1 and S2 heart sounds, which are associated with ventricular contraction, occur at the beginning and end, respectively, of the ejection phase. The S1 and S2 heart sounds are produced by closing of the atrioventricular valves and semilunar valves of heart 16, respectively.

After the ejection phase, cardiac cycle 78 includes a passive filing stage during diastole, during which passive filling of the ventricles may produce the S3 heart sound. Additionally, near the end of diastole, an atrial contraction 82 occurs, actively filling of the ventricles. The active filing of the ventricles may produce the S4 heart sound. The atrial depolarization that resulted in atrial contraction 82 is not present in cardiac electrogram 70. Another cardiac cycle begins with ventricular depolarization 74B, and the resulting ventricular contraction 80B.

Mechanical sensing module 60 detects atrial contractions, and may also detect ventricular contractions, based on an analysis of a motion signal generated by motion sensor 58. The motion signal generated by motion sensor 58 may vary based on the movement of tissue of heart 16, as well as any associated mechanical perturbations or vibrations, during contraction of heart 16. Mechanical perturbations or vibrations may include those associated with the S1-S4 heart sounds discussed above. For example, mechanical sensing module 60 may detect an atrial contraction based on features in motion signal 72 that are indicative of movement of cardiac tissue during atrial contraction, and/or the presence of mechanical perturbations associated with the S4 heart sound. As another example, mechanical sensing module 60 may detect a ventricular contraction based on features in motion signal 72 that are indicative of movement of cardiac tissue during ventricular contraction, and/or the presence of mechanical perturbations associated with the S1 heart sound.

FIG. 6 is a timing diagram illustrating an example technique for delivering atrio-synchronous ventricular pacing based on atrial contraction detection. The timing diagram of FIG. 6 includes a ventricular marker channel, and a corresponding motion signal. According to the example technique for delivering atrio-synchronous ventricular pacing based on atrial contraction detection, mechanical sensing module 60

identifies an activation of a ventricle, e.g., right ventricle 18. An activation of a ventricle may be an intrinsic or paced depolarization of the ventricle, or a mechanical contraction of the ventricle. Mechanical sensing module 60 may identify activation of a ventricle by determining that electrical sensing module 56 detected an intrinsic depolarization 90A of the ventricle, by determining that stimulation module 54 delivered a pacing pulse to the ventricle, or by detecting mechanical contraction 92A of ventricle.

In response to identifying activation of the ventricle, mechanical sensing module 60 waits for an atrial contraction detection delay period 94, and then analyzes the motion signal generated by motion sensor 58 within an atrial contraction detection window 96 that begins the atrial contraction detection delay period 94 after the activation of the ventricle, i.e., that begins upon completion of the atrial contraction detection delay period 94. In the example of FIG. 6, mechanical sensing module 60 determined that electrical sensing module detected ventricular depolarization 90A, and analyzes the motion signal within atrial contraction detection window 96 that begins atrial contraction detection delay period 94 after detection of ventricular depolarization 90A.

Starting atrial contraction detection window 96 upon completion of atrial contraction delay period 94 may allow mechanical sensing module 60 to avoid misidentifying ventricular contraction 92A, or other motion of heart during the cardiac cycle prior to atrial depolarization and contraction, as an atrial contraction. In some examples, atrial contraction delay period 94 is at least approximately 300 milliseconds. In some examples, atrial contraction delay period 94 is at least approximately 400 milliseconds, or is approximately 400 milliseconds. In some examples, atrial contraction detection delay period 94 is at least approximately 600 milliseconds. In some examples, processing module 50 and/or mechanical sensing module 60 adjusts atrial contraction detection delay period 94 based on a heart rate of patient 14, e.g., based on one or more intervals between consecutive intrinsic ventricular depolarizations detected by electrical sensing module 56. For example, processing module 50 and/or mechanical sensing module 60 may increase atrial contraction detection delay period 94 as heart rate decreases, and decrease atrial contraction detection delay period 94 as heart rate increases. In some examples, a clinician or other user may program a length of atrial contraction delay period 94, e.g., using programmer 22. The user may select the length of atrial contraction delay period 94 based on individual patient characteristics.

Based on the analysis of the motion signal within atrial contraction detection window 96, mechanical sensing module 60 may detect atrial contraction 98. Mechanical sensing module 60 may extend atrial contraction detection window 96, and the associated analysis of the motion signal, until detection of atrial contraction 98, or until a subsequent intrinsic ventricular depolarization 90B is detected by electrical sensing module 56, or a subsequent ventricular pacing pulse 104 is delivered by stimulation module 54. In some examples, as described above, mechanical sensing module 60 filters the motion signal within atrial contraction detection window 96. Mechanical sensing module 60 may also rectify the motion signal within atrial contraction detection window 96. In some examples, mechanical sensing module 60 detects atrial contraction 98 by comparing an amplitude of the motion signal within atrial contraction detection window 96 to a threshold 100. In some examples, mechanical sensing module 60 determines a derivative signal of the motion signal, e.g., the filtered and/or rectified motion

signal, and compares an amplitude of the derivative signal, which represents the rate of change of the motion signal, to threshold 100. In some examples, mechanical sensing module 60 detects the time of atrial contraction 98 as the earliest time point at which the amplitude of the motion signal, or it derivative signal, exceeds threshold 100.

In some examples, threshold 100 is a constant value, which may be determined by a manufacturer of an LPD 12A, or programmed by a clinician using programmer 22. In other examples, mechanical sensing module 60 and/or processing module 50 determines threshold 100 based on a peak amplitude of the motion signal during one or more previously detected atrial contractions. For example, mechanical sensing module 60 and/or processing module 50 may determine that threshold 100 is a value within a range from approximately 20 percent to approximately 80 percent, such as approximately 50 percent, of the peak amplitude of the motion signal during the most recently detected atrial contraction, or of an average peak amplitude of the motion signal during a plurality of previously detected atrial contractions.

In some examples, instead of or in addition to detection of atrial contraction 98 based on a comparison of the motion signal to threshold 100, mechanical sensing module 60 may detect atrial contraction 98 using morphological comparison techniques. For example, mechanical sensing module 60 may compare the motion signal within atrial contraction detection window 96 to one or more templates representing one or more features of a motion signal during atrial contraction. Mechanical sensing module 60 may detect atrial contraction 98 at the point when a statistic resulting from the comparison indicates a sufficient level of similarity between the motion signal and the one or more templates.

In some examples, processing module 50 determines whether electrical sensing module 56 detects an intrinsic ventricular depolarization 90B resulting from the atrial depolarization that led to atrial contraction 98. For example, processing module 50 may determine whether electrical sensing module 56 detects intrinsic ventricular depolarization 90B within an AV interval 102 that begins upon detection of atrial contraction 98 by mechanical sensing module 60. If electrical sensing module 56 does not detect intrinsic depolarization 90B within AV interval 102, e.g., because it did not occur due to AV nodal block, then processing module 50 controls electrical stimulation module 54 to generate and deliver ventricular pacing pulse 104 at the expiration of AV interval 102. In this manner, LPD 12A delivers atrio-synchronous ventricular pacing based on detection of atrial contractions.

Due to the delay between atrial depolarization and atrial contraction 98, and the resulting temporal proximity between atrial contraction 98 and the time at which a paced or intrinsic ventricular depolarization should occur, AV interval 102, which may be referred to as a mechanical AV interval, may be shorter than an (electrical) AV interval employed by a pacemaker that provides atrio-synchronous ventricular pacing based on detection of atrial depolarizations. In some examples, AV interval 102 is less than approximately 100 milliseconds. In some examples, AV interval 102 is less than approximately 50 milliseconds. In some examples, AV interval 102 is approximately 30 milliseconds. In some examples, mechanical AV interval 102 is approximately 20 to 30 milliseconds shorter than an electrical AV interval for the patient.

In some examples, processing module 50 does not employ an AV interval. In such examples, upon detection of atrial contraction 98 by mechanical sensing module 60, processing

15

module determines whether electrical sensing module **56** has detected intrinsic ventricular depolarization **90B**. If electrical sensing module **56** has not detected intrinsic ventricular depolarization **90B**, then processing module **50** controls stimulation module **54** to generate and deliver a ventricular pacing pulse.

In some examples, LPD **12A** determines whether the delivery of ventricular pacing pulse **104** was effective based on detection of the ventricular contraction **92B** resulting from the delivery of pacing pulse **104**. In such examples, mechanical sensing module **60** detects ventricular contraction **92B** based on the motion signal, e.g., based on a comparison of the motion signal to a threshold **106** in a manner similar to that employed for detection of atrial contraction **98** based on threshold **100**, or based on a morphological analysis. In some examples, mechanical sensing module **60** detects the time of ventricular contraction **110** to be the first time-point after delivery of pacing pulse **104** when the amplitude of the motion signal exceeds threshold **106**. Mechanical sensing module **60** and/or processing module **50** may determine an interval **108** from delivery of pacing pulse **104** to a time of detection of ventricular contraction **92B**. Mechanical sensing module **60** may also determine a peak amplitude **110** of the motion signal during ventricular contraction **92B**.

In some examples, processing module **50** adjusts AV interval **102** based on the determination of whether the delivery of pacing pulse **104** to the ventricle was effective. For example, processing module **50** may decrease AV interval **102** in response to determining that interval **108** is less than a threshold. Additionally or alternatively, processing module **50** may increase AV interval **102** in response to determining that peak amplitude **110** is greater than a threshold.

FIG. **7** is a flow diagram of an example technique for delivering atrio-synchronous ventricular pacing based on atrial contraction detection that may be performed by a LPD implanted within a ventricle, such as LPD **12A** or LPD **12B** implanted within right ventricle **18** of heart **16**. The example technique of FIG. **7** may be performed, at least in part, by a processing module **50** of such an LPD. According to the example technique of FIG. **7**, the LPD identifies ventricular activation (**120**), and detects a subsequent atrial contraction based on a motion signal generated by a motion sensor of the LPD (**122**). The LPD then determines whether an intrinsic ventricular depolarization resulting from the atrial depolarization that caused the detected atrial contraction has been detected, e.g., within an AV interval beginning upon detection of the atrial contraction (**124**).

If the LPD detects an intrinsic ventricular depolarization resulting from the atrial depolarization that caused the detected atrial contraction (YES of **124**), then the LPD identifies the intrinsic ventricular depolarization as a ventricular activation that begins the next cardiac cycle (**120**). If the LPD does not detect an intrinsic ventricular depolarization resulting from the atrial depolarization that caused the detected atrial contraction (NO of **124**), then the LPD delivers a ventricular pacing pulse (**126**). For example, the LPD may deliver a ventricular pacing pulse upon expiration of the AV interval without detecting an intrinsic ventricular depolarization. The LPD identifies delivery of the ventricular pacing pulse as a ventricular activation that begins the next cardiac cycle (**120**). The LPD may also determine whether the delivery of the cardiac pacing pulse was effective, e.g., as described above with respect to FIG. **6** (**128**).

FIG. **8** is a flow diagram illustrating an example technique for detecting an atrial contraction based on analysis of a

16

motion signal (e.g., **122** of FIG. **7**) that may be performed by a LPD implanted within a ventricle, such as LPD **12A** or LPD **12B** implanted within right ventricle **18** of heart **16**. The example technique of FIG. **8** may be performed, at least in part, by a processing module **50** of such an LPD. According to the example technique of FIG. **8**, the LPD begins an atrial contraction detection delay period upon identification of a ventricular activation event (**130**). The LPD begins an atrial contraction detection window upon expiration of the atrial contraction delay period (**132**). The LPD analyzes the motion signal generated by the motion sensor of the LPD within the atrial contraction detection window.

The LPD filters the motion signal within the atrial contraction detection window, rectifies the filtered signal, and generates a derivative signal of the filtered and rectified motion signal within the atrial contraction detection window (**134**). The LPD determines whether an amplitude of the derivative signal within the atrial contraction detection window exceeds a threshold (**136**). In response to determining that the amplitude of the derivative signal within the atrial contraction detection window exceeds the threshold (YES of **136**), the LPD detects an atrial contraction (**138**).

FIG. **9** is a flow diagram illustrating an example technique for verifying efficacy of atrio-synchronous ventricular pacing based on atrial contraction detection that may be performed by a LPD implanted within a ventricle, such as LPD **12A** or LPD **12B** implanted within right ventricle **18** of heart **16**. According to the example technique of FIG. **9**, the LPD detects a ventricular contraction resulting from a ventricular pacing pulse based on the motion signal generated by a motion sensor of the LPD after delivery of the ventricular pacing pulse (**140**). For example, the LPD may detect a time of the ventricular contraction as a time when an amplitude of the motion signal, e.g., an amplitude of a derivative signal generated from a filtered and rectified motion signal, exceeds a threshold.

The LPD determines an interval from the delivery of the ventricular pacing pulse to the time of detection of the ventricular contraction (**142**). The LPD determines whether the interval is less than a threshold (**144**). If the interval is less than the threshold (YES of **144**), then the LPD decreases an AV interval used for delivery of atrio-synchronous ventricular pacing pulses after detection of an atrial contraction (**146**).

If the interval is not less than the threshold, e.g., is greater than the threshold (NO of **144**), then the LPD determines a peak amplitude of the motion signal during the detected ventricular contraction (**148**). The LPD determines whether the peak amplitude of the motion signal during the detected ventricular contraction is greater than a threshold (**150**). If the peak amplitude is greater than the threshold (YES of **150**), then the LPD increases an AV interval used for delivery of atrio-synchronous ventricular pacing pulses after detection of an atrial contraction (**152**). If the peak amplitude is not greater than the threshold, e.g., is less than the threshold (NO of **150**), then the LPD maintains the AV interval at its current value (**154**).

FIG. **10** is a flow diagram illustrating an example technique for switching between an atrio-synchronous ventricular pacing mode and an asynchronous pacing mode that may be performed by a LPD implanted within a ventricle, such as LPD **12A** or LPD **12B** implanted within right ventricle **18**. The example technique of FIG. **10** may be performed, at least in part, by a processing module **50** of such an LPD. According to the example technique of FIG. **10**, the LPD operates in an atrio-synchronous ventricular pacing mode in

which the LPD delivers atrio-synchronous ventricular pacing based detection of atrial contractions, as described herein (160). The atrio-synchronous ventricular pacing mode in which the LPD delivers atrio-synchronous ventricular pacing based detection of atrial contractions may be similar to a conventional VDD pacing mode, and may be referred to as a VDD pacing mode.

The LPD determines whether a patient activity level, or a level of motion experienced by the patient, exceeds a threshold (162). The LPD may determine the patient activity or motion level based on the motion signal generated by the motion sensor of the LPD. If the activity or motion level exceeds the threshold (YES of 162), then the LPD switches to an asynchronous ventricular pacing mode (164). In the asynchronous ventricular pacing mode, the LPD may deliver pacing pulses to the ventricle if an intrinsic ventricular depolarization is not detected within a VV interval from the last paced or intrinsic ventricular depolarization. The asynchronous ventricular pacing mode of the LPD may be similar to a conventional VVI or VVIR pacing mode, and may be referred to as a WI or VVIR pacing mode.

If the activity or motion level does not exceed the threshold, e.g., is less than the threshold (NO of 162), then the LPD determines whether the heart rate is greater than a threshold, e.g., greater than approximately 80 beats-per-minute or approximately 100 beats-per-minute, and/or irregular (166). The LPD may determine the heart rate and its regularity based on intervals between previous ventricular depolarizations. If the heart rate is greater than the threshold and/or irregular (YES of 166), then the LPD switches to the asynchronous ventricular pacing mode (164).

If the heart rate is not greater than the threshold and/or not irregular (NO of 166), then the LPD determines whether it is able to detect atrial contractions based on an analysis of the motion signal generated by a motion sensor of the LPD (168). For example, the LPD may determine that it is unable to detect atrial contractions if it determines that it has not detected atrial contractions for a predetermined number of cardiac cycles. The predetermined number of cardiac cycles may be any number of one or more cardiac cycles, which may be consecutive or non-consecutive. For example, the predetermined number of cardiac cycles may be three. If LPD determines that it is unable to detect atrial contraction (NO of 168), then the LPD switches to the asynchronous ventricular pacing mode (170). If the LPD determines that it is unable to detect atrial contractions (NO of 168), then the LPD may also change a motion signal sensing vector according to which the LPD derives the motion signal from one or more of a plurality of signals generated by the motion sensor, e.g., the plurality accelerometers of the motion sensor (172).

If the LPD determines that it is able to detect atrial contractions (YES of 168), then LPD may continue to deliver ventricular pacing according to the atrio-synchronous ventricular pacing mode (160). Further, after delivering pacing according to the asynchronous pacing mode (164, 170) for a period of time, or until a condition that led to the switch to the asynchronous mode has abated, the LPD may switch to delivery of ventricular pacing according to the atrio-synchronous ventricular pacing mode.

FIG. 11 is a flow diagram illustrating an example technique for switching between atrio-synchronous ventricular pacing in response to atrial depolarizations and atrio-synchronous ventricular pacing in response to atrial contractions that may be performed by a LPD implanted within a ventricle, such as right ventricle 18, that is able to detect depolarizations of an atrium, such as right atrium 20. LPD

12B that is coupled to sensing extension 40 is one example of such an LPD, although LPD 12A may also be configured to detect depolarizations of the atrium. The example technique of FIG. 11 may be performed by a processing module 50 of such an LPD.

According to the example technique of FIG. 11, the LPD delivers atrio-synchronous pacing a first, electrical AV interval after detection of atrial depolarizations (180). The LPD determines whether it is unable to detect atrial depolarizations (182). For example, the LPD may determine that it is unable to detect atrial depolarizations if it determines that it has not detected atrial depolarizations for a predetermined number of cardiac cycles, e.g., has not detected an atrial depolarization between consecutive ventricular depolarizations of a predetermined number of cardiac cycles. The predetermined number of cardiac cycles may be any number of one or more cardiac cycles, which may be consecutive or non-consecutive. If LPD determines that it is unable to detect atrial depolarizations (YES of 182), then the LPD may activate atrial contraction detection, and switch to delivery of atrio-synchronous pacing a second, mechanical AV interval after detection of atrial contractions (184). If LPD determines that it is able to detect atrial depolarizations (NO of 182), or some time delivering atrio-synchronous ventricular pacing based on atrial contraction detection (184), then the LPD may continue or switch back to delivery of atrio-synchronous ventricular pacing based on atrial depolarization detection (180).

The techniques described in this disclosure, including those attributed to LPDs 12, programmer 22, or various constituent components, may be implemented, at least in part, in hardware, software, firmware or any combination thereof. For example, various aspects of the techniques may be implemented within one or more processors, including one or more microprocessors, DSPs, ASICs, FPGAs, or any other equivalent integrated or discrete logic circuitry, as well as any combinations of such components, embodied in programmers, such as physician or patient programmers, stimulators, image processing devices or other devices. The term "processor" or "processing circuitry" may generally refer to any of the foregoing logic circuitry, alone or in combination with other logic circuitry, or any other equivalent circuitry.

Such hardware, software, firmware may be implemented within the same device or within separate devices to support the various operations and functions described in this disclosure. In addition, any of the described units, modules or components may be implemented together or separately as discrete but interoperable logic devices. Depiction of different features as modules or units is intended to highlight different functional aspects and does not necessarily imply that such modules or units must be realized by separate hardware or software components. Rather, functionality associated with one or more modules or units may be performed by separate hardware or software components, or integrated within common or separate hardware or software components.

When implemented in software, the functionality ascribed to the systems, devices and techniques described in this disclosure may be embodied as instructions on a computer-readable medium such as RAM, ROM, NVRAM, EEPROM, FLASH memory, magnetic data storage media, optical data storage media, or the like. The instructions may be executed to support one or more aspects of the functionality described in this disclosure.

Various examples have been described. These and other examples are within the scope of the following claims.

What is claimed is:

1. A leadless pacing device configured to deliver atrio-synchronous ventricular pacing, the leadless pacing device comprising:

a plurality of electrodes;

a motion sensor configured to generate a motion signal [as a function of] *based on* movement of a heart of a patient;

[a] stimulation [module] *circuitry* coupled to the plurality of electrodes, wherein the stimulation [module] *circuitry* is configured to generate pacing pulses and deliver the pacing pulses to a ventricle of the heart via the plurality of electrodes;

[an] electrical sensing [module] *circuitry* coupled to the plurality of electrodes, wherein the electrical sensing [module] *circuitry* is configured to detect depolarizations of the ventricle within a cardiac electrogram sensed via the plurality of electrodes;

[a] mechanical sensing [module] *circuitry* coupled to the motion sensor and configured to:

receive the motion signal from the motion sensor;

identify an activation of the ventricle;

[upon] *in response to* identification of the activation of the ventricle, initiate an atrial contraction detection delay period;

analyze the motion signal within an atrial contraction detection window that begins upon completion of the atrial contraction detection delay period; and

detect a contraction of an atrium of the heart based on the analysis of the motion signal within the atrial contraction detection window;

[a] processing [module] *circuitry* configured to control the stimulation [module] *circuitry* to generate a pacing pulse and deliver the pacing pulse to the ventricle via the plurality of electrodes in response to the detection of the contraction of the atrium by the mechanical sensing [module] *circuitry*; and

a housing configured to be implanted within the ventricle, wherein the housing encloses the motion sensor, the stimulation [module] *circuitry*, the electrical sensing [module] *circuitry*, the mechanical sensing [module] *circuitry*, and the processing [module] *circuitry*;

wherein the processing [module] *circuitry* is configured to:

determine that the electrical sensing [module] *circuitry* did not detect a depolarization of the ventricle within an atrioventricular (AV) interval [beginning] *timed from* when the mechanical sensing [module] *circuitry* detected the contraction of the atrium; and

control the stimulation [module] *circuitry* to generate the pacing pulse and deliver the pacing pulse to the ventricle via the plurality of electrodes in response to the determination; and,

wherein the mechanical sensing [module] *circuitry* is configured to detect a contraction of the ventricle based on the motion signal after delivery of the pacing pulse to the ventricle, and the processing [module] *circuitry* is configured to [.] determine whether the delivery of the pacing pulse to the ventricle was effective based on the detection of the contraction of the ventricle [.] and adjust the AV interval based on the determination of whether the delivery of the pacing pulse to the ventricle was effective [.]

2. The leadless pacing device of claim 1, wherein the processing [module] *circuitry* is configured to:

determine that an interval from the delivery of the pacing pulse to the detection of the contraction of the ventricle is less than a threshold; and

decrease the AV interval in response to the determination that the interval from the delivery of the pacing pulse to the detection of the contraction of the ventricle is less than the threshold.

3. The leadless pacing device of claim 1, wherein the mechanical sensing [module] *circuitry* is configured to:

detect a peak of the [ventricular] contraction of the ventricle based on the motion signal; and

determine an amplitude of the motion signal at the peak, and

wherein the processing [module] *circuitry* is configured to:

determine that the amplitude is greater than the threshold; and

increase the AV interval in response to the determination that the amplitude is greater than the threshold.

4. A leadless pacing device configured to deliver atrio-synchronous ventricular pacing, the leadless pacing device comprising:

a plurality of electrodes;

a motion sensor configured to generate a motion signal [as a function of] *based on* movement of a heart of a patient;

[a] stimulation [module] *circuitry* coupled to the plurality of electrodes, wherein the stimulation [module] *circuitry* is configured to generate pacing pulses and deliver the pacing pulses to a ventricle of the heart via the plurality of electrodes;

[an] electrical sensing [module] *circuitry* coupled to the plurality of electrodes, wherein the electrical sensing [module] *circuitry* is configured to detect depolarizations of the ventricle within a cardiac electrogram sensed via the plurality of electrodes, *wherein the electrical sensing circuitry is further configured to detect depolarizations of at least one atrium of the heart*;

[a] mechanical sensing [module] *circuitry* coupled to the motion sensor and configured to:

receive the motion signal from the motion sensor;

identify an activation of the ventricle;

[upon] *in response to* identification of the activation of the ventricle, initiate an atrial contraction detection delay period;

analyze the motion signal within an atrial contraction detection window that begins upon completion of the atrial contraction detection delay period; and

detect a contraction of an atrium of the heart based on the analysis of the motion signal within the atrial contraction detection window;

[a] processing [module] *circuitry* configured to control the stimulation [module] *circuitry* to generate [a] *one or more* pacing [pulse] *pulses* and deliver the pacing [pulse] *pulses* to the ventricle via the plurality of electrodes [in response to the detection of the contraction of the atrium by the mechanical sensing module]; and

a housing configured to be implanted within the ventricle, wherein the housing encloses the motion sensor, the stimulation [module] *circuitry*, the electrical sensing [module] *circuitry*, the mechanical sensing [module] *circuitry*, and the processing [module] *circuitry*;

[wherein the processing module is configured to:
determine that the electrical sensing module did not
detect a depolarization of the ventricle within an
atrioventricular (AV) interval beginning when the
mechanical sensing module detected the contraction
of the atrium; and
control the stimulation module to generate the pacing
pulse and deliver the pacing pulse to the ventricle via
the plurality of electrodes in response to the deter-
mination; and,
wherein the AV interval comprises a mechanical AV
interval,
wherein the electrical sensing module is configured to
detect depolarizations of the atrium within the cardiac
electrogram sensed via the plurality of electrodes,]
wherein, in response to the electrical sensing [module]
circuitry detecting a depolarization of the atrium, the
processing [module] circuitry is configured to:
determine that the electrical sensing [module] circuitry
did not detect a depolarization of the ventricle within
an electrical *atrioventricular* (AV) interval [begin-
ning] *timed from* when the electrical sensing [mod-
ule] circuitry detected the depolarization of the
atrium; and
control the stimulation [module] circuitry to generate
[a] *one of the* pacing [pulse] *pulses* and deliver the
pacing pulse to the ventricle via the plurality of
electrodes in response to the determination that the
electrical sensing [module] circuitry did not detect a
depolarization of the ventricle,
wherein the processing [module] circuitry is further con-
figured to determine that the electrical sensing [mod-
ule] circuitry did not detect a depolarization of the
atrium during [a predetermined number of] one or more
cardiac cycles and, in response to the determination:
control the mechanical sensing [module] circuitry to
detect [a] *the* contraction of the atrium based on the
motion signal;
determine that the electrical sensing [module] circuitry
did not detect a depolarization of the ventricle within
[the] *a* mechanical AV interval [beginning] *timed*
from when the mechanical sensing [module] cir-
cuitry detected the contraction of the atrium; and
control the stimulation [module] circuitry to generate
[a] *one of the* pacing [pulse] *pulses* and deliver the
pacing pulse to the ventricle via the plurality of
electrodes in response to the determination that the
mechanical sensing [module] circuitry did not detect
a depolarization of the ventricle, and
wherein the electrical AV interval is greater than the
mechanical AV interval.

5. A leadless pacing device configured to deliver atrio-
synchronous ventricular pacing, the leadless pacing device
comprising:
a plurality of electrodes;
a motion sensor configured to generate a motion signal [as
a function of] *based on* movement of a heart of a
patient;
[a] stimulation [module] circuitry coupled to the plurality
of electrodes, wherein the stimulation [module] cir-
cuitry is configured to generate pacing pulses and
deliver the pacing pulses to a ventricle of the heart via
the plurality of electrodes;
[an] electrical sensing [module] circuitry coupled to the
plurality of electrodes, wherein the electrical sensing
[module] circuitry is configured to detect depolariza-

tions of the ventricle within a cardiac electrogram
sensed via the plurality of electrodes;
[a] mechanical sensing [module] circuitry coupled to the
motion sensor and configured to:
receive the motion signal from the motion sensor;
identify an activation of the ventricle;
[upon] *in response to* identification of the activation of
the ventricle, initiate an atrial contraction detection
delay period;
analyze the motion signal within an atrial contraction
detection window that begins upon completion of the
atrial contraction detection delay period; and
detect a contraction of an atrium of the heart based on
the analysis of the motion signal within the atrial
contraction detection window;
[a] processing [module] circuitry configured to control the
stimulation [module] circuitry to generate a pacing
pulse and deliver the pacing pulse to the ventricle via
the plurality of electrodes in response to the detection
of the contraction of the atrium by the mechanical
sensing [module] circuitry; and
a housing configured to be implanted within the ventricle,
wherein the housing encloses the motion sensor, the
stimulation [module] circuitry, the electrical sensing
[module] circuitry, the mechanical sensing [module]
circuitry, and the processing [module] circuitry;
wherein the processing [module] circuitry is configured
to:
determine a heart rate of the patient based on depolar-
izations detected by the electrical sensing [module]
circuitry;
determine that the heart rate exceeds a threshold; and
control the stimulation [module] circuitry to generate
pacing pulses and deliver the pacing pulses to the
ventricle according to an asynchronous ventricular
pacing mode [in response to] *based on* the determi-
nation that the heart rate exceeds the threshold.

6. A leadless pacing device configured to deliver atrio-
synchronous ventricular pacing, the leadless pacing device
comprising:
a plurality of electrodes;
a motion sensor configured to generate a motion signal [as
a function of] *based on* movement of a heart of a
patient;
[a] stimulation [module] circuitry coupled to the plurality
of electrodes, wherein the stimulation [module] cir-
cuitry is configured to generate pacing pulses and
deliver the pacing pulses to a ventricle of the heart via
the plurality of electrodes;
[an] electrical sensing [module] circuitry coupled to the
plurality of electrodes, wherein the electrical sensing
[module] circuitry is configured to detect depolariza-
tions of the ventricle within a cardiac electrogram
sensed via the plurality of electrodes;
[a] mechanical sensing [module] circuitry coupled to the
motion sensor and configured to:
receive the motion signal from the motion sensor;
identify an activation of the ventricle;
[upon] *in response to* identification of the activation of
the ventricle, initiate an atrial contraction detection
delay period;
analyze the motion signal within an atrial contraction
detection window that begins upon completion of the
atrial contraction detection delay period; and
detect a contraction of an atrium of the heart based on
the analysis of the motion signal within the atrial
contraction detection window;

23

[a] processing [module] *circuitry* configured to control the stimulation [module] *circuitry* to generate a pacing pulse and deliver the pacing pulse to the ventricle via the plurality of electrodes in response to the detection of the contraction of the atrium by the mechanical sensing [module] *circuitry*; and
 a housing configured to be implanted within the ventricle, wherein the housing encloses the motion sensor, the stimulation [module] *circuitry*, the electrical sensing [module] *circuitry*, the mechanical sensing [module] *circuitry*, and the processing [module] *circuitry*;
 wherein the motion sensor comprises a plurality of accelerometers, each of the plurality of accelerometers oriented along a respective axis and configured to generate a respective accelerometer signal,
 wherein mechanical sensing [module] *circuitry* derives the motion signal based on a first one or more of the accelerometer signals according to a first sensing vector, and
 wherein the processing [module] *circuitry* is configured to:
 determine that the mechanical sensing [module] *circuitry* did not detect a contraction of the atrium during [a predetermined number of] one or more cardiac cycles; and
 control the mechanical sensing [module] *circuitry* to derive the motion signal based on a second one or more of the accelerometer signals according to a second sensing vector [in response to] *based on* the determination.

7. A method for delivering atrio-synchronous ventricular pacing by a leadless pacing device implanted within a ventricle of a heart of a patient, the method comprising:
 identifying an activation of the ventricle;
 [upon] *in response to* identification of the activation of the ventricle, initiating an atrial contraction detection delay period;
 analyzing a motion signal within an atrial contraction detection window that begins upon completion of the atrial contraction detection delay period, wherein the motion signal is generated by a motion sensor of the leadless pacing device [as a function of] *based on* movement of the heart;
 detecting a contraction of an atrium of the heart based on the analysis of the motion signal within the atrial contraction detection window; [and
 delivering a pacing pulse to the ventricle in response to the detection of the atrial contraction;
 determining that a depolarization of the ventricle resulting from the depolarization of the atrium that caused the contraction of the atrium was not detected within an atrioventricular (AV) interval beginning when the contraction of the atrium was detected;
 delivering the pacing pulse to the ventricle in response to the determination;]
 determining that a depolarization of the ventricle resulting from the depolarization of the atrium that caused the contraction of the atrium was not detected within an atrioventricular (AV) interval [beginning] *timed from* when the contraction of the atrium was detected; [and]
 delivering [the] a pacing pulse to the ventricle in response to the determination;
 detecting a contraction of the ventricle based on the motion signal after delivery of the pacing pulse to the ventricle; *and*

24

determining whether the delivery of the pacing pulse to the ventricle was effective based on the detection of the contraction of the ventricle; and
 adjusting the AV interval based on the determination of whether the delivery of the pacing pulse to the ventricle was effective].

8. The method of claim 7, further comprising:
 determining that an interval from the delivery of the pacing pulse to the detection of the contraction of the ventricle is less than a threshold; and
 decreasing the AV interval in response to the determination that the interval from the delivery of the pacing pulse to the detection of the contraction of the ventricle is less than the threshold.

9. The method of claim 7, further comprising:
 detecting a peak of the [ventricular] contraction *of the ventricle* based on the motion signal;
 determining an amplitude of the motion signal at the peak;
 determining that the amplitude is greater than the threshold; and
 increasing the AV interval in response to the determination that the amplitude is greater than the threshold.

10. A method for delivering atrio-synchronous ventricular pacing by a leadless pacing device implanted within a ventricle of a heart of a patient, the method comprising:
 [identifying an activation of the ventricle;
 upon identification of the activation of the ventricle, initiating an atrial contraction detection delay period;
 analyzing a motion signal within an atrial contraction detection window that begins upon completion of the atrial contraction detection delay period, wherein the motion signal is generated by a motion sensor of the leadless pacing device as a function of movement of the heart;
 detecting a contraction of an atrium of the heart based on the analysis of the motion signal within the atrial contraction detection window; and
 delivering a pacing pulse to the ventricle in response to the detection of the atrial contraction;
 determining that a depolarization of the ventricle resulting from the depolarization of the atrium that caused the contraction of the atrium was not detected within an atrioventricular (AV) interval beginning when the contraction of the atrium was detected;
 delivering the pacing pulse to the ventricle in response to the determination;
 determining that a depolarization of the ventricle resulting from the depolarization of the atrium that caused the contraction of the atrium was not detected within an atrioventricular (AV) interval beginning when the contraction of the atrium was detected; and
 delivering the pacing pulse to the ventricle in response to the determination;
 wherein the leadless pacing device is configured to detect depolarizations of the atrium, and the AV interval comprises a mechanical AV interval, the method further comprising:]
 in response to detecting a depolarization of [the] *an atrium of the heart*:
 determining that a depolarization of the ventricle was not detected within an electrical *atrioventricular* (AV) interval [beginning when the electrical sensing module detected] *timed from the detection of* the depolarization of the atrium; and
 delivering a pacing pulse to the ventricle in response to the determination that a depolarization of the ventricle was not detected, and

25

in response to determining that a depolarization of the atrium was not detected during [a predetermined number of] one or more cardiac cycles;

detecting a contraction of the atrium based on [the] a motion signal;

determining that a depolarization of the ventricle was not detected within [the] a mechanical AV interval [beginning] *timed from* when the contraction of the atrium was detected; and

delivering a pacing pulse to the ventricle in response to the determination that a depolarization of the ventricle was not detected, and

wherein the electrical AV interval is greater than the mechanical AV interval, *and*

wherein detecting the contraction of the atrium based on the motion signal comprises:

identifying an activation of the ventricle;

in response to identification of the activation of the ventricle, initiating an atrial contraction detection delay period;

analyzing a motion signal within an atrial contraction detection window that begins upon completion of the atrial contraction detection delay period, wherein the motion signal is generated by a motion sensor of the pacing device based on movement of the heart;

and

detecting the contraction of the based on the analysis of the motion signal within the atrial contraction detection window.

11. A method for delivering atrio-synchronous ventricular pacing by a leadless pacing device implanted within a ventricle of a heart of a patient, the method comprising:

identifying an activation of the ventricle;

[upon] *in response to* identification of the activation of the ventricle, initiating an atrial contraction detection delay period;

analyzing a motion signal within an atrial contraction detection window that begins upon completion of the atrial contraction detection delay period, wherein the motion signal is generated by a motion sensor of the leadless pacing device [as a function of] *based on* movement of the heart;

detecting a contraction of an atrium of the heart based on the analysis of the motion signal within the atrial contraction detection window; and

delivering a pacing pulse to the ventricle in response to the detection of the atrial contraction[;], *wherein the motion signal is further generated by the motion sensor based on motion of the patient, the method further comprising:*

determining an amount of motion of the patient based on the motion signal; and

delivering the pacing pulses to the ventricle according to an asynchronous ventricular pacing mode [in response to] *based on* the amount of motion of the patient exceeding a threshold.

12. A method for delivering atrio-synchronous ventricular pacing by a leadless pacing device implanted within a ventricle of a heart of a patient, the method comprising:

identifying an activation of the ventricle;

[upon] *in response to* identification of the activation of the ventricle, initiating an atrial contraction detection delay period;

analyzing a motion signal within an atrial contraction detection window that begins upon completion of the atrial contraction detection delay period, wherein the

26

motion signal is generated by a motion sensor of the leadless pacing device [as a function of] *based on* movement of the heart;

detecting a contraction of an atrium of the heart based on the analysis of the motion signal within the atrial contraction detection window; and

delivering a pacing pulse to the ventricle in response to the detection of the atrial contraction[;], *the method further comprising:*

determining a contraction of the atrium was not detected during [a predetermined number of] one or more cardiac cycles; and

delivering pacing pulses to the ventricle according to an asynchronous ventricular pacing mode [in response to] *based on* the determination.

13. A method for delivering atrio-synchronous ventricular pacing by a leadless pacing device implanted within a ventricle of a heart of a patient, the method comprising:

identifying an activation of the ventricle;

[upon] *in response to* identification of the activation of the ventricle, initiating an atrial contraction detection delay period;

analyzing a motion signal within an atrial contraction detection window that begins upon completion of the atrial contraction detection delay period, wherein the motion signal is generated by a motion sensor of the leadless pacing device [as a function of] *based on* movement of the heart;

detecting a contraction of an atrium of the heart based on the analysis of the motion signal within the atrial contraction detection window; and

delivering a pacing pulse to the ventricle in response to the detection of the atrial contraction[;], *the method further comprising:*

determining that a heart rate *of the heart* exceeds a threshold; and

delivering [the] *one or more additional* pacing pulses to the ventricle according to an asynchronous ventricular pacing mode [in response to] *based on* the determination that the heart rate exceeds the threshold.

14. *The leadless pacing device of claim 1, wherein the AV interval begins when the mechanical sensing circuitry detected the contraction of the atrium.*

15. *The leadless pacing device of claim 1, wherein the processing circuitry is configured to adjust the AV interval based on the determination of whether the delivery of the pacing pulse to the ventricle was effective.*

16. *The leadless pacing device of claim 4, wherein the electrical sensing circuitry is configured to detect the depolarizations of the at least one atrium via the plurality of electrodes.*

17. *The leadless pacing device of claim 4, wherein the processing circuitry is configured to control the mechanical sensing circuitry to detect the contraction of the atrium based on the motion signal in response to determining that the electrical sensing circuitry did not detect a depolarization of the atrium during a predetermined number of one or more cardiac cycles.*

18. *The method of claim 7, further comprising adjusting the AV interval based on the determination of whether the delivery of the pacing pulse to the ventricle was effective.*

19. *The method claim 10, wherein detecting the contraction of the atrium based on the motion signal comprises detecting the contraction of the atrium in response to*

27

determining that the depolarization of the atrium was not detected during a predetermined number of one or more cardiac cycles.

20. The method of claim 12, wherein determining the contraction of the atrium was not detected during one or more cardiac cycles comprises determining the contraction of the atrium was not detected during a predetermined number of one or more cardiac cycles.

21. A leadless pacing device configured to deliver atrio-synchronous ventricular pacing, the leadless pacing device comprising:

a plurality of electrodes;

a motion sensor configured to generate a motion signal based on movement of a heart of a patient;

stimulation circuitry coupled to the plurality of electrodes, wherein the stimulation circuitry is configured to generate pacing pulses and deliver the pacing pulses to a ventricle of the heart via the plurality of electrodes;

electrical sensing circuitry coupled to the plurality of electrodes, wherein the electrical sensing circuitry is configured to detect depolarizations of the ventricle within a cardiac electrogram sensed via the plurality of electrodes;

mechanical sensing circuitry coupled to the motion sensor and configured to:

receive the motion signal from the motion sensor;

identify an activation of the ventricle;

in response to identification of the activation of the ventricle, initiate an atrial contraction detection delay period;

analyze the motion signal within an atrial contraction detection window that begins upon completion of the atrial contraction detection delay period; and

detect a contraction of an atrium of the heart based on the analysis of the motion signal within the atrial contraction detection window;

processing circuitry configured to:

determine that the electrical sensing circuitry did not detect a depolarization of the ventricle within an atrioventricular (AV) interval timed from when the mechanical sensing circuitry detected the contraction of the atrium; and

control the stimulation circuitry to generate a pacing pulse and deliver the pacing pulse to the ventricle via the plurality of electrodes in response to the determination; and

a housing configured to be implanted within the ventricle, wherein the housing encloses the motion sensor, the stimulation circuitry, the electrical sensing circuitry, the mechanical sensing circuitry, and the processing circuitry;

wherein the processing circuitry is further configured to:

determine a heart rate of the heart; and

adjust the atrial contraction detection delay period based on the determined heart rate.

22. A leadless pacing device configured to deliver atrio-synchronous ventricular pacing, the leadless pacing device comprising:

a plurality of electrodes;

a motion sensor configured to generate a motion signal based on movement of a heart of a patient;

stimulation circuitry coupled to the plurality of electrodes, wherein the stimulation circuitry is configured

28

to generate pacing pulses and deliver the pacing pulses to a ventricle of the heart via the plurality of electrodes; electrical sensing circuitry coupled to the plurality of electrodes, wherein the electrical sensing circuitry is configured to detect depolarizations of the ventricle within a cardiac electrogram sensed via the plurality of electrodes;

mechanical sensing circuitry coupled to the motion sensor and configured to:

receive the motion signal from the motion sensor;

identify an activation of the ventricle;

in response to identification of the activation of the ventricle, initiate an atrial contraction detection delay period;

analyze the motion signal within an atrial contraction detection window that begins upon completion of the atrial contraction detection delay period; and

detect a contraction of an atrium of the heart based on the analysis of the motion signal within the atrial contraction detection window;

processing circuitry configured to:

determine that the electrical sensing circuitry did not detect a depolarization of the ventricle within an atrioventricular (AV) interval timed from when the mechanical sensing circuitry detected the contraction of the atrium; and

control the stimulation circuitry to generate a pacing pulse and deliver the pacing pulse to the ventricle via the plurality of electrodes in response to the determination; and

a housing configured to be implanted within the ventricle, wherein the housing encloses the motion sensor, the stimulation circuitry, the electrical sensing circuitry, the mechanical sensing circuitry, and the processing circuitry;

wherein the processing circuitry is further configured to:

identify a condition inconsistent with atrio-synchronous ventricular pacing; and control the stimulation circuitry to deliver one or more additional pacing pulses to the ventricle according to an asynchronous ventricular pacing mode based on the identification of the condition.

23. The leadless pacing device of claim 22, wherein the motion sensor is configured to generate the motion signal based on motion of the patient and, to identify the condition inconsistent with atrio-synchronous ventricular pacing, the processing circuitry is configured to determine, based on the motion signal, that an amount of motion of the patient satisfies a threshold.

24. The leadless pacing device of claim 22, wherein, to identify the condition inconsistent with atrio-synchronous ventricular pacing, the processing circuitry is configured to determine that a contraction of the atrium was not detected during one or more cardiac cycles.

25. The leadless pacing device of claim 22, wherein, to identify the condition inconsistent with atrio-synchronous ventricular pacing, the processing circuitry is configured to determine that a heart rate of the heart satisfies a threshold.

26. The leadless pacing device of claim 22, wherein, to identify the condition inconsistent with atrio-synchronous ventricular pacing, the processing circuitry is configured to determine that a heart rate irregularity of the heart satisfies a threshold.
