A host device is configured to read and write information from and into a card and to supply a supply voltage that belongs to a first voltage range or a second voltage range which is lower than the first voltage range, and issues a voltage identification command to the card. The voltage identification command includes a voltage range identification section, an error detection section, and a check pattern section. The voltage range identification section includes information indicating which one of the first voltage range and the second voltage range the supply voltage belongs. The error detection section has a pattern configured to enable the card which has received the voltage identification command to detect errors in the voltage identification command. The check pattern section has a preset pattern.

The entire contents of each of these documents are incorporated herein by reference.

## BACKGROUND OF THE INVENTION

## 1. Field of the Invention

The present invention relates to a card and a host device, and relates, for example to checking of operating voltage and capacity of the memory card and host device.

## 2. Description of the Related Art

In recent years, a memory card, which is one type of removable storage device, has been heavily used in various portable electronic devices such as personal computers, PDAs, cameras, and mobile phones. PC cards and small-size SD™ cards draw much attention as memory cards. The SD™ card is a memory card which has a flash memory, a card controller and the like built-in, and is designed in

particular to meet the demands of increased compactness, larger capacities and higher speeds.

Conventionally, an operating voltage of a memory card and its host device has been 3.3 V (high voltage) range and has supported a voltage range from 2.7 V to 3.6 V. Demand has arisen for operation with a lower voltage, for example, in 1.8 V (low voltage) range, in other words, which supports a voltage range of 1.65 V to 1.95 V, for example.

In addition, the capacity of a conventional memory card is not sufficient for storing large volumes of data, and a SD™ card which store large volumes of data is desired.

## BRIEF SUMMARY OF THE INVENTION

According to an aspect of the present invention, there is provided a host device configured to read and write information from and into a card and to supply a supply voltage that belong to a first voltage range or a second voltage range which is lower than the first voltage range, the host device configured to issue to the card a voltage identification command including a voltage range identification section, an error detection section, and a check pattern section, wherein the voltage range identification section includes information indicating which one of the first voltage range and the second voltage range the supply voltage belongs, the error detection section has a pattern configured to enable the card which has received the voltage identification command to detect errors in the voltage identification command, and the check pattern section has a preset pattern.

According to an aspect of the present invention, there is provided a card comprising a memory which stores information and a controller to control the memory, the card being operable at only a voltage that lies within a first voltage range, or at a voltage that lies within the first voltage range and a voltage that lies within a second voltage range which is lower than the first voltage range, and the card being supplied with a voltage identification command including a voltage range identification section, an error detection section, and a check pattern section, wherein, the card issues a response including a voltage range identification section and an error detection section or a check pattern section in response to the voltage identification command, the voltage range identification section of the response has the same pattern as the voltage range identification section of the voltage identification command, the error detection section of the response has a pattern configured to enable a device which has received the response to detect errors in the response, and the check pattern section of the response has the same pattern as the check pattern of the voltage identification command.

## BRIEF DESCRIPTION OF THE SEVERAL VIEWS OF THE DRAWING

FIG. 1 is a diagram schematically showing the main parts of a card and a host device according to a first embodiment of the present invention.

FIG. 6 is a flowchart showing a process for checking an operating voltage range in the case where the host device operates in a high voltage range.

FIG. 7 is a flowchart of a process for checking an operating voltage range in the case where the host device operates in a low voltage range.

FIG. 8 is a diagram showing the main parts of the content of a memory initialization command according to a second embodiment of the present invention.

FIG. 9 is a diagram showing the main parts of the content of a response to the memory initialization command according to the second embodiment.

FIG. 10 is a flowchart showing a memory initialization process according to the second embodiment of the invention.

### DETAILED DESCRIPTION OF THE INVENTION

Embodiments of the present invention will be described in the following with reference to the accompanying drawings. Note that the structural elements that have substantially the same function and configuration in the following description are assigned the same numbers, and repeated description is provided only when necessary.

#### First Embodiment

A first embodiment relates to reciprocal checking of an operating voltage range which a host device and a card support.

It is expected that when a card which can operate in low voltage is realized, a card that supports only high voltage operation (high voltage card), a card that supports high voltage and low voltage (dual-voltage card), and a host device that supplies low voltage and a host device that supplies high voltage exist in market.

As a result, when the host device that supplies low voltage (low voltage host device) and the high voltage card are used together, the following problems may arise. When a card is inserted into the host device, it is initialized by commands from the host device. At the initialization, the host device issues to the card commands for acquiring information in a register that stores information relating to operation conditions that is provided in the card. The host device can acquire information on the voltage supported by the card from the information.

When the information relating to the operation conditions is acquired, the high voltage card operates by a low voltage power supply that a host supplies and outputs information from the operation conditions register even though it does not support a low voltage operation. However, the validity of transmission/reception of the operation conditions register information cannot be guaranteed because the card operates by a voltage which it does not support. For this reason, the host device attempts initialization of the inserted card and in the case where the initialization fails to know that the card does not support the low voltage operation.

Note that when the conventional host device that supplies high voltage and the two-voltage card are used together, there is no particular problem because both can operate at high voltage.

FIG. 1 schematically shows the main parts of the card and host device according to the first embodiment of the invention. As shown in FIG. 1, the card 1 includes a memory 3 and a card controller 4.

4

The card 1 supports only a high voltage operation (for example, 3.3 V) or supports both high voltage and low voltage operations (for example, 1.8 V). Note that low voltage operation refers, in reality, that the card 1 and the host device 2 are configured to support a voltage range including 1.8 V (such as 1.65 V to 1.95 V). Similarly, the high voltage operation refers that the card 1 and the host device 2 are configured to support a voltage range including 3.3 V (such as 2.7 V to 3.6 V). Typically, the range of the operating voltage itself is the same for both the card 1 and the host device 2. An unused voltage region is provided between the low voltage range and the high voltage range.

The host device 2 includes a voltage supply section 5, a read/write section 6, and a command control section 7. The voltage supply section 5 operates with a high voltage or low voltage power source potential V<sub>dd</sub>, and the power source potential V<sub>dd</sub> and a common potential V<sub>ss</sub> are supplied to the card. The read/write section 6 reads data from the card 1 and writes data onto the card 1. The command control section 7 transmits and receives commands and responses to and from the card 1. Reference numerals 11, 12, 13, 14 and 17 will be explained in a second embodiment.

A NAND type flash memory may be used as the memory 3. FIG. 2 shows arrangement of data in the NAND type flash memory. Each page of the NAND type flash memory 11 has 2122 Bytes ((512 Bytes data memory section+16 Bytes redundant section)×4), and 128 pages form one erasure unit (256 kBytes+8 kBytes).

In addition, the NAND type flash memory 21 has a page buffer 21A for inputting and outputting data into and from the flash memory. The memory capacity of the page buffer 21A is 2112 Bytes (2048 Bytes+64 Bytes). At the time of data writing and the like, the page buffer 21A performs processing of inputting and outputting data into and from the flash memory in 1 page units corresponding to its own capacity.

When the memory capacity of the NAND flash memory 21 is, for example, 1 Gbit, the number of 256-kByte blocks (erasure units) is 512. In addition, the NAND flash memory 21 is manufactured by using, for example, 0.09-μm process technology. That is, the design rule of the NAND type flash memory 21 is less than 0.1 μm.

Meanwhile, the embodiment shows the case where the erasure unit is a 256-kByte block, but construction such that the erasure unit is, for example, a 16-kByte block is also advantageous in practical use. In this case, each page has 528 Bytes ((512 Bytes data memory section+16 Bytes redundant section), and 32 pages form one deletion unit (16 kBytes+0.5 kBytes (k is 1024)). In addition, the NAND flash memory 21 may be a binary memory which stores 1 bit of information in one memory cell, or may be a multi-value memory which stores 2 bits or more of information in one memory cell.

Next, the initialization method using the card 1 and the host device 2 in FIG. 1 will be described with reference to FIGS. 3 to 7. The initialization process includes various processings. First, an outline of commands issued by the host device 2 up until immediately before memory initialization will be described. FIG. 3 shows an example of the commands issued by the host device 2 up until immediately before memory initialization. Note that the card 1 and the memory 2 operates with the operating voltage until information is acquired from the operation conditions register of the memory 2 by a memory initialization command described hereinafter. During this time, the card 1 must be operable by the operating voltage.

## 5

As shown in FIG. 3, when initialization is started, the host device 2 issues a reset command CMDR to reset circuits in the card 1.

Next, the host device 2 issues a voltage check command CMDV. The command is a newly introduced command in this embodiment. For this reason, the conventional card 1 does not recognize the voltage check command CMDV, and even if it receives this command, it does not send back a response to the host device 2. The host device 2 and the card 1 can check the operating voltage (operating voltage range) supported by each other using the voltage check command CMDV. The reciprocal checking method will be described in detail hereinafter.

Next, if the card 1, for example, supports various I/O functions that are expanded from a data storage function, the host device 2 issues an initialization command CMDIO to the card 1. Subsequently, an initialization command for the memory 1 is supplied. Memory initialization will be described using the second embodiment.

Now, the voltage check command CMDV will be described. FIG. 4 shows the main parts of the content of the voltage check command CMDV. As shown in FIG. 4, the voltage check command CMDV has at least a check pattern section CPS and a voltage range identification section VOLS. The voltage range identification section VOLS has a pattern which uniquely shows whether the host device 2 supports a low voltage operation or a high voltage operation.

The check pattern section CPS and the voltage range identification section VOLS can have any number of bits. However, it is preferable that the following conditions are satisfied. Namely, as described in the following, the operation of the host device 2 and the card 1 examine whether the bit pattern of the voltage range identification section VOLS match or not to check the operating voltage range for each other. For this reason, the check pattern section CPS may be, for example, about 8 bits and the voltage range identification section VOLS may be, for example, about 4 bits in order to avoid incorrect recognition when the pattern for this section changes due to noise. The command section CM has an index for identifying this command.

In order to check whether or not the command is correctly transmitted from the host device 2 to the card 1, the voltage check command CMDV has an error detection code section ED which uses an error detection code section ED using an error detection code or the like such as CRC (Cycle Redundancy Check). The card 1 can detect an error inside the voltage check command CMDV by using the error detection code.

FIG. 5 shows the main parts of the content of a response to the voltage check command CMDV. As shown in FIG. 5, the response to the voltage check command includes at least a check pattern section CPA and a voltage range identification section VOLA. The card 1 forms the same bit pattern as the voltage check command CMDV in the check pattern section CPA, and forms the same bit pattern as the voltage range identification section VOLS in the voltage range identification section VOLA to thereby send a response to the host device. The response may have an error detection code section ED as in the case of the voltage check command CMDV. The host device 2 can use the error detection code or compare the response with the command to determine if they match in order to detect errors in the response of the voltage check command CMDV.

Next, description will be given to a method in which the host device 2 and the card 1 check the operating voltage range which each other supports by using the voltage check command CMDV. The process differs depending on a high

## 6

voltage range operation or a low voltage range operation. First, the process of the high voltage range operation will be described. FIG. 6 is a flowchart showing a process for checking the operating voltage range when the host device 2 operates in the high voltage range. As shown in FIG. 6, the host device 2 issues the voltage check command CMDV to the card 1 in step ST1.

In step ST2, the host device 2 determines whether or not there is a response to the voltage check command CMDV. As described above, the conventional card does not recognize the voltage check command CMDV, and thus does not issue a response to the command. For this reason, the host device 2 determines that the card 1 is not a low voltage card, or in other words, it determines that the process by the high voltage operation can be continued, and takes the memory initialization process. The memory initialization process will be described in the second embodiment.

Meanwhile, when the card 1 under initialization is the card of this embodiment, the card 1 sends back the response shown in FIG. 5 to the host device 2. At this step, the card 1 first observes a bit pattern of the voltage range identification section VOLS of the voltage check command CMDV. Then, the card 1 sends back the response which has the same bit pattern as this bit pattern in the voltage range identification section VOLA.

Next, in step ST3, the host device 2 checks the matching of the pattern of the voltage range identification section VOLA in the response and the pattern of the voltage range identification section VOLS in the voltage check command CMDV. When these pattern match, the host device 2 determines that the card 1 is a new card for which the voltage check command CMDV can be checked and that the operating voltage range of the host device 2 is supported.

Simultaneously, the host device 2 executes CRC check or checks that the bit pattern of the response matches the bit pattern of the command. Consequently, it can be confirmed that the transmission and reception of the voltage check command CMDV are reliable.

In the case of a bus mode with an error detection code in a command, the pattern of the error detection code section ED in the response is formed into, for example, a CRC code to check the validity of the response. In the case of a bus mode without error detection code section ED in the voltage check command CMDV, the voltage range identification section VOLS and the voltage range identification section VOLA as well as the check pattern sections CPS and CPA of the command and response respectively match, and the response is determined to be normal. If the response is determined to be normal, the voltage check process ends. Then, the flow transfers to the memory initialization process. This will be described in the second embodiment.

On the other hand, if the voltage range identification section VOLS and the voltage range identification section VOLA do not match and/or the check pattern section CPS and the check pattern section CPA do not match, and an error is detected by the error detection code, the process for checking the operating voltage range ends. As a result, the initialization process stops.

FIG. 7 is a flowchart showing a process for checking the operating voltage range when the operating voltage of the host device 2 is within the low voltage range. The difference between the low voltage operation and the high voltage operation lies only in the following point. Namely, if there is no response from the card 1 in step ST2, this means that the card 1 does not operate with low voltage. Thus, the

initialization process stops in order to avoid initialization on the high voltage card by the host device **2** that operates in the low voltage range.

According to the card **1** and the host device **2** of the first embodiment of the invention, the card **1** and the host device **2** can know the operating voltage range that each other supports based on transmission/reception of the newly provided command. For this reason, the subsequent initialization process can be performed by normal operation using the operating voltage range that the card **1** and the host device **2** both support. In addition, when the operating voltage range that both support do not match, the host device **2** can detect this and cancel the initialization process. As a result, it is possible to avoid wasteful process such as initialization in an abnormal state and a malfunction of the host.

In addition, according to the first embodiment, the voltage check command CMDV has a check pattern, and the card **1** forms the same pattern as the check pattern in the response to the voltage check command CMDV. Comparing the check patterns can provide guarantee of the reliability of transmission and reception of the voltage check command CMDV. Accordingly, even when the bus mode without code error detection section in each command, errors can be detected in the response.

#### Second Embodiment

A second embodiment relates to a method of memory initialization depending on whether a memory loaded in a card is of a large capacity or a small capacity.

With the realization of a card capable of storing large volume of information (large capacity card), it is necessary to newly set a format corresponding to the large capacity card. A file system of a new format is different from that of a conventional low capacity format. In addition, a conventional host device which uses the low capacity format cannot recognize the file system of the large capacity card. For this reason, if the conventional host device initializes the large capacity card, data on the card may be destroyed.

The following four combinations are possible according to whether or not the host device supports large capacity and whether or not the card that is being initialized supports large capacity.

- (1) Conventional host device (which does not support large capacity)+small capacity card
- (2) Conventional host device+large capacity card
- (3) Large capacity supporting host device (also supports small capacity)+small capacity card
- (4) Large capacity supporting host device+large capacity card.

It is desirable that the host device and/or the card detect which of the above cases applies and responds accordingly.

As shown in FIG. 1, a card **11** according to the second embodiment of the invention is loaded with a small capacity or large capacity memory **13** and a card controller **14**. A host device **12** includes a command control section **17**. The command control section **17** is configured to support a memory initialization command of the second embodiment described and both the small capacity card and the large capacity card as well as the functions of the command control section **7** of the first embodiment.

The content of the memory initialization command differs depending on where the process reaches in the flowchart of the first embodiment. If the results of the operating voltage range checking determines that the process has reached A in FIG. 6, the host device **12** has a function for issuing the voltage check command CMDV and is thus not a conven-

tional format, or in other words, it supports large capacity. In addition, the case in which the card being initialized is a small capacity card, the case (3) above is applicable. In this case, the host device **12** issues a conventional memory initialization command. The card controller **14** of the card **1** receives the conventional memory initialization command to initialize the memory into a mode that is compatible with the prior art.

On the other hand, in the case where the process reaches B in FIG. 6 or FIG. 7, the host device **12** performs memory initialization by using a new initialization command shown hereinafter. FIG. 8 shows the main parts of the content of the new memory initialization command according to the second embodiment of the invention. As shown in FIG. 8, the memory initialization command includes a first voltage identification section V1S, a second voltage identification section V2S, a capacity identification section HCS, and a busy notification section BS. The second voltage identification section V2S may be omitted, and only the first voltage identification section V1S may be defined.

The first voltage identification section V1S is configured by, for example, multiple bits, and each bit corresponds to a specific width of voltage (such as 0.1 V). A voltage range supported by the first voltage identification section V1S is the same as the high voltage operation range of the first embodiment. A bit showing the voltage being currently applied at the host device **12** is set to "1".

The second voltage identification section V2S may be configured by 1 bit. It may also be formed of a plurality of bits. The bit is set if the host device **12** applies voltage in the low voltage range. When the second voltage identification section V2S is configured by multiple bits, the width of the voltage covered by each bit in the second voltage identification section V2S can be less than that for the first voltage identification section V1S, and may be unit of 0.05 V, for example. By doing this, even if the operating voltage of the host device and the card is decreased even further in the future, the host device can show its own operating voltage in more detail. A voltage range supported by the second voltage identification section V2S is the same as the low voltage range of the first embodiment.

A middle voltage range section VM is provided between time voltage range covered by the first voltage identification section V1S and the voltage range covered by the second voltage identification section V2S. The host device **12** does not support the voltage range corresponding to the middle voltage range section VM, and as a consequence, all of the bits in the middle voltage range section VM never show "1".

The following advantages are obtained by providing the middle voltage range section VM. The card controller **14** has a voltage regulator in order that the card **11** can correspond to two operating voltage ranges. The voltage regulator determines whether a supply voltage from the host device **12** is high voltage or low voltage, and changes the supply voltage to the operating voltage of the card **11**. At this time, if two operating voltage ranges are successive, the voltage regulator finds it difficult to determine a voltage which is substantially in the middle of the two operating voltage ranges. As a result, the operation slowly progresses. To avoid that, a region that is not for use is provided to help the voltage regulator easily determine the range of the supply voltage.

The capacity identification section HCS has a pattern which indicates whether the host device **12** supports only small capacity or both small capacity and large capacity. The busy notification section BS is set to 0 or 1 in the response, and is constant (for example, 0) in the command. The new

memory initialization command may have an error detection section ED composed of a CRC code and the like.

FIG. 9 shows the main parts of the content of the response of the memory initialization command according to the second embodiment. As shown in FIG. 9, each part of the response of the memory initialization command has the same format as the command, and includes a first voltage identification section V1A, a second voltage identification section V2A, a capacity identification section HCA, and a busy notification signal BA.

The first voltage identification section V1A has the same number of bits as the first voltage identification section V1S in the command, and all of the bits corresponding to the operating voltage that the card 11 itself supports may be, for example, "1".

Similarly, the second voltage identification section V2A also has the same number of bits as the second voltage identification section V2S in the command. All of the bits corresponding to the operating voltage that the card 11 itself supports may be, for example, "1".

The capacity identification section HCA indicates whether the card 11 is a small capacity card or a large capacity card. The busy notification section BS forms a bit pattern during the memory initialization, the bit pattern indicating this fact.

Next, the method for memory initialization will be described with reference to FIG. 10. FIG. 10 is a flowchart showing the memory initialization process according to the second embodiment of the invention. FIG. 10 shows the portion following A and B in FIGS. 6 and 7. That at least both the card 11 and the host device 12 support issuing the voltage check command CMDV is necessary to issue a new memory initialization command. In addition, when the card 11 is a large capacity card, the new memory initialization command must be issued.

As shown in FIG. 10, in step ST11, the host device 12 issues a new memory initialization command shown in FIG. 8. If the host device 12 supports a large capacity card, the capacity identification section HCS of this command is set to a bit pattern that indicates that the host device 12 supports a large capacity card.

Note that when the host device is a conventional type, the voltage check command CMDV and the memory initialization command (new memory initialization command) according to this embodiment are not issued. In addition to it, when the card being initialized is a small capacity card, which corresponds to (1) above, the card 11 is initialized (including the operation of the card 11 sending back a response) in a mode that is compatible with the prior art by means of the conventional initialization command.

When the host device is the conventional type, and the card 11 that being initialized is a large capacity card, which corresponds to (2) above, the card 11 which has not received the voltage check command CMDV does not complete initialization instructed by the memory initialization command in order to cancel the initialization process. The host device, then, detects that the initialization could not be performed based on a time limit check. This makes it possible to prevent initialization of the large capacity card by the small capacity format in error.

Next, in step ST12, the host device 12 determines existence of a response to the new memory initialization command. When no response is received, it is assumed that an error occurred and the processing ends. When a response is received, the host device 12 checks in step ST13 the bit pattern of the busy notification section BA in the response. The host device 12 keep issuing the memory initialization

command until the initialization of the memory ends and the bit pattern indicates that memory initialization has ended (step ST14). Once initialization of the memory 13 starts, the card only sends back a response and ignores the content that has been set in the memory initialization command parameters. The host device 12 checks the limits for the time for which the memory 13 is being initialized.

When the initialization of the memory 13 is complete, the host device 12 checks the bit pattern of the capacity identification section HCA in the response in step ST15. The capacity identification section HCA comes in effect when initialization ends. If the card 11 being initialized is a new card and of a small capacity card, HCA=0 is shown, which corresponds to the case (3) above. As a result, the host device 12 knows that the card has been initialized as a small capacity card. If it is a large capacity card, HCA=1 is shown, which corresponds to the case (4) above. As a result, the host device 12 knows that the card has been initialized as a large capacity card. The process, then, transfers to an additional process (for example, acquisition of an ID of the card 11).

In the host device 12 and the card 11 according to the second embodiment of the invention, the memory initialization command and response includes support information and identifying information for the small capacity card or the large capacity card. The host device 12 and the card 11 use it to check whether a host device with which it is in communication supports large capacity. The high capacity card 11 is initialized only when both the host device 12 and the card 11 support high capacity. The small capacity card is initialized only when both the host device 12 and the card 11 support small capacity. Also, because the host device 12 which supports large capacity must also support small capacity, the initialization process is cancelled when the small capacity host attempts to initialize the large capacity card 11. Consequently, even when the new or old host devices are used with the new or old cards, errors in operation can be prevented.

In addition, various modifications and adjustments within the scope of the present invention may occur to one skilled in the art, and it is to be understood that these modifications and adjustments are included in the scope of the invention.

According to the present invention, a card and a host device can be provided, in which reciprocal checking of the operating voltage and capacity is possible.

What is claimed is:

[1. A memory card comprising:

a memory; and

a controller which

controls the memory,

receives from a host device a first command which includes a voltage identification section which has a bit pattern selected from two bit patterns, the bit pattern indicating voltages which the host device supports,

determines whether the memory card supports the voltages indicated by the bit pattern in the voltage identification section of the first command, and

issues a response which includes a voltage identification section which has the same bit pattern as the bit pattern in the voltage identification section of the first command when the memory card determines that the memory card supports the voltages indicated by the bit pattern in the voltage identification section of the first command.]

[2. The card of claim 1, wherein

the memory card does not issue a response when the memory card determines that the memory card does not

11

support the voltages indicated by the bit pattern in the voltage identification section of the first command.]

[3. The card of claim 1, wherein:

the first command further includes an error detection code section which has an error detection code and a check pattern section which has a bit pattern, and

the memory card issues the response which further includes an error detection section which has an error detection code and a check pattern section which has the same bit pattern as the bit pattern in the check pattern section of the first command.]

[4. A host device which:

reads and writes data from and into a memory card, issues a first command which includes a voltage identification section which has a bit pattern selected from two bit patterns, the bit pattern indicating voltages which the host device supports,

performs initialization of the memory card when the host device receives a response which includes a voltage identification section which has the same bit pattern as the bit pattern in the voltage identification section of the first command, and

terminates initialization of the memory card when the host device does not receive a response to the first command.]

[5. The device of claim 4, wherein:

the first command further includes an error detection code section which has an error detection code and a check pattern section which has a bit pattern, and

the host device performs initialization of the memory card when the host device receives the response which further includes an error detection section which has an error detection code which indicates no error and a check pattern section which has the same bit pattern as the bit pattern in the check pattern section of the first command.]

[6. The device of claim 4, wherein:

the host device issues an initialization command which instructs the memory card to perform initialization when the host device receives a response which includes a voltage identification section which has the same bit pattern as the bit pattern in the voltage identification section of the first command, and

the host device does not issue an initialization command which instructs the memory card to perform initialization when the host device does not receive a response

12

which includes a voltage identification section which has the same bit pattern as the bit pattern in the voltage identification section of the first command.]

7. *A memory system including a host device and a memory device and being operated between the host device and the memory device, wherein the host device issues a first command to the memory device, the first command including an argument which indicates a range of voltage supplied by the host device, the memory device receives the first command and returns a response of the first command to the host device when a range of voltage supported by the memory device matches the range of voltage indicated in the argument, the host device issues a second command to the memory device, when the host device does not receive a response from the memory device to the first command, the memory device receives the second command with a first definition, supports a second command with the first definition, and returns a response of the second command with the first definition; when the host device receives a response from the memory device to the first command, the memory device receives the second command with a second definition, supports the second command with the second definition, upon reception of the second command, performs initialization of the memory device according to either the first definition or the second definition, and returns a result of the initialization of the memory device with response to the second command with the first definition or a result of the initialization of the memory device with response to the second command with the second definition.*

8. *The system of claim 7, wherein the second definition in the response of the second command corresponds to the second definition in the second command.*

9. *The system of claim 8, wherein the second command with the second definition includes a capacity support section and the response to the second command with the second definition includes a capacity identification section.*

10. *The system of claim 9, wherein: the capacity support section in the second command with the second definition indicates whether the host device supports a small capacity or supports both a small capacity and a large capacity; and the capacity identification section in the response to the second command with the second definition indicates which one of a small capacity memory device and a large capacity memory device the memory device has been initialized as.*
